There are many chemical substances which, although difficult to determine quantitatively in very dilute solutions by chemical methods, have the property of strong selective absorption of light. According to the law of Beer, the absorption coefficient of a solution is directly proportional to the concentration. Since this law holds with fair accuracy for most dilute solutions, it follows that the colour change in transmitted light obtained by varying the concentration (within certain ranges) can be exactly imitated by increasing the thickness of the medium which must be traversed; thus, if 1 cm. of solution A gives the same colour as 10 cm. of solution B, we should expect (provided that the above law held) that the amount of material dissolved in unit volume of A is ten times that of B. The application of this principle to find the concentration of a solution of unknown strength, given one of the same material and of known strength, is quite clear. Failing a means of using different thickness of solution, the alternative is to prepare a number of samples of known concentration and to endeavour to place the unknown in its relation to the rest a method much less elegant, but of value when Beer's law is likely to break down. In practice, no such liberties as indicated above in the 'ten to one' example are advisable. According to Thorpe, if the strength of the standard differs by more than 10 per cent from that of the test liquid, it is usual to dilute one or the other (in a known ratio) before comparison, so that the lengths to be compared are approximately equal.

It is not possible in a short article to do more than indicate some of the numerous applications of the method. It is used in the estimation of small quantities of the salts of copper, tin, lead, iron, cobalt, manganese, and other metals; also in the determination of dyes and natural colouring materials. Krüss mentions the estimation of salicylic acid in surgical wadding, and the examination of the coloration given by animal charcoal. Other applications are met in the operations of the oil, sugar, and brewing industries. Special instruments with artificial standards are applied in the determination of the sugar content of the blood of diabetic patients. An account of practical methods will be found in Lunge-Berl's "Chemische-technische Untersuchungsmethoden", vols. 1, 2, 3, and 4, and in books such as "Colorimetric Analysis", by B. Snell.

The early methods of application of the principle were of the simplest description; an account of them is given in Thorpe's "Dictionary of Applied Chemistry", vol. 2, p. 340. Flat-ended tubes placed side by side were often employed, sky-light being reflected through their lengths by a mirror. It is well known, however, that the exact comparison of separated colour fields is very difficult. In 1910 Autenreith and Königsberger[1] used a colorimeter with a Helmholtz 'Doppelplatte' for approximating the comparison fields. A movable hollow wedge affords the means of varying the thickness of the test solution. This was used for the determination of hæmatin in blood and other medical work. Another early suggestion aiming at better optical accuracy was that of H. Krüss,[2] who suggested the use of the Swan or Lummer-Brodhun double prism in order to secure a comparison field with an indefinitely narrow separation.

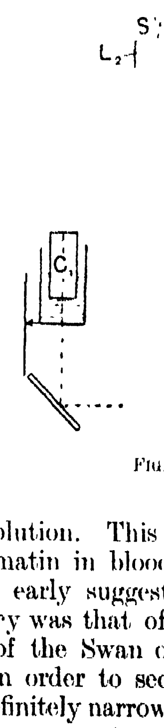

FIG. 1.

The most practical arrangement was, however, due to Duboscq,[3] who gave the instrument its most usual modern form, Fig. 1. The rays traversing the vertical cylinders holding the solutions are brought into one field by the use of two rhomb reflectors; or a single symmetrical rhomb can be employed. A lens brings these groups of parallel rays into one focus, where a telecentric stop is placed so as to prevent stray light from reaching the eye. The eye-lens helps to bring the sharp line of separation into exact visual focus in the field of view. In order to vary the thickness of solution traversed, the vessels containing the solution (shaded in the figure) can each be moved on vertical slides by rack and pinion. Thus the flat-ended cylinders, either closed tubes or glass rods

made of the finest and most colourless glass, dip more or less into the liquid, and the consequent thickness of the layer on each side can be read off on a suitable scale. Alternatively, the rods alone may be moved. The light is usually derived from the sky, and reflected upwards by a mirror through each tube; it is advisable, however, to use an artificial source with a 'daylight' filter and a suitable diffusing screen if inconsistencies due to the variation of the sky are to be avoided. A good example of such an instrument as described above is made by Messrs. Hawksley and Sons, Ltd.

There are numerous variations of the usual pattern, such as may be found in the catalogues of the various makers. We shall, however, only have space to mention efforts which have been made to overcome certain difficulties. The simple account above assumed that the colour is entirely produced by the substance in solution. It may be, however, that the solvent is coloured, or has other coloured substances present. To meet this difficulty, the Bürker compensating colorimeter of Messrs. Leitz, Fig. 2, is provided with two auxiliary vessels of the same depth introduced into the respective beams. One is filled with a solution of accurately known strength while the other is filled with the solvent only. The two cylinders or rods are now moved together; they dip into the two cups, one of which contains the solvent, and the other holds the solution under test. Naturally, the cup containing the solution is placed beneath the auxiliary vessel containing the solvent only, so that when balance is obtained the thickness of the strata of liquid in each beam is equal, which is not the case in the simpler form of the instrument. Hence any *difference* of coloration in the two fields must be entirely due to the solute; equality can be established by the adjustment of the plungers provided that the standard and test solutions are of comparable concentrations.

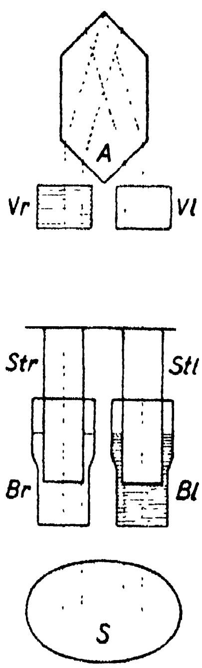

FIG. 2.

The accuracy of such measurements is naturally facilitated by the precision of manufacture of the parts. The cylinders should be accurately ground, and, in cases where the greatest accuracy in the thickness of the cells is required, the plane and pieces may be pressed on in optical contact and maintained in position by suitable clamps; thus the uncertainties and chemical objections connected with the use of cements can be avoided.

The accuracy of comparison also depends on the visual sensitiveness of the eye. Where pure intensity comparisons are concerned, the optimum sensitiveness of the eye corresponds to a difference threshold (dI/I) of about 2 per cent. If we may be permitted a little mathematical shorthand, the intensity of the light transmitted by a thickness t of a solution of concentration c is given by

$$I = I_0 e^{-kct},$$

k being the absorption coefficient for unit concentration. It is easily found that (dI/I) with t constant $= -kt\,dc$, while (dI/I) with c constant $= -kc\,dt$. With low concentrations we need a greater thickness to obtain a given absolute accuracy of measurement, and with small thickness we need greater concentrations. Let the transmission coefficient of the layer, that is, $I/I_0 = T$, then $-kt = (\log T)/c$, so that if $dI/I = 0{\cdot}02$ (say) $= -kt\,dc$, we obtain $dc/c = 0{\cdot}02/\log T$, so that the proportional accuracy would depend on having a fairly big absorption of light, but just as in the case of the polarimeter, this makes the visual accuracy smaller and a compromise must be reached. The settings, moreover, do not involve pure intensity comparisons and are likely to depend more on 'saturation discrimination'. The usual presence of dichroism may also cause here changes which help to make the settings more sensitive; in fact, the thorough discussion of the accuracy of the instrument is a very complicated matter. In certain cases the use of a suitable filter might vastly enhance the sensitiveness.

This note would be incomplete without a reference to the recently introduced instruments which effect the comparison by the aid of a photo-electric cell or cells, as in the equipment manufactured by the Cambridge Instrument Co., Ltd. There are a number of ways in which the photo-electric comparison can be effected. It is possible to use two cells in a bridge form of circuit as in the Cambridge instrument, the cells being exposed to beams passing respectively through a test solution and through a standard solution; any deviation from equality can be recorded by a suitable valve amplification system adapted for alternating current. Alternatively, the light may be passed alternately through two such tubes, the two beams falling intermittently into the same cell. A lack of equality of the photo-electric currents is detected by a synchronised rectifier and suitable amplification. Nor are photo-electric cells the only possibility for recording changes of absorption. The Moll 'nephelometer and absorptiometer' furnishes objective records of comparative absorption with the aid of a pair of balanced thermopiles of the Moll pattern. This instrument is made by Messrs. Kipp and Zonen. A considerable improvement on the visual accuracy is effected by the physical detectors.

Such instruments can obviously be applied for obtaining continuous records of fluid products during the course of manufacture, and illustrate once more the ways in which optical methods of control may save much time and trouble.

[3] Duboscq lived about fifty years ago, and it has not been possible to trace any original description of the Duboscq instrument. The firm of Duboscq has now been succeeded by Pellin. Messrs. Jobin and Yvon, Paris, also make colorimeters.

Obituary.

SIR FRANCIS WATTS, K.C.M.G.

THE death of Sir Francis Watts, which occurred on Sept. 26, terminates a career of devoted service to the West Indies. The son of John Watts of Ilfracombe, Francis Watts was born in 1859. He was educated privately and at Mason College, Birmingham, the forerunner of the present University of that city. His official connexion with the West Indies commenced in 1889, when he was appointed analytical chemist in Antigua, but an earlier association with these islands was formed as chemist to the Montserrat Company, Ltd. It was this earlier association which directed his early studies to citric acid. He was transferred in 1898 to Jamaica for a brief period, but returned to the Leeward Islands as Government Chemist and Superintendent of Agriculture.

In 1898, on the recommendation of the Royal Commission appointed to report on the depression caused by the slump in sugar, was formed the Imperial Department of Agriculture for the West Indies. The first years of that Department saw a great development of the sugar industry throughout the West Indies, and Francis Watts played a prominent part in that development, notably in the establishment of central factories in Antigua and St. Kitts, which was rendered possible by the grant-in-aid given by the Imperial Government to the West Indies in 1902 to enable them to tide over the period between the signing of the Brussels Convention for the abolition of the sugar bounties and the date on which it came into force. When, therefore, the time came, in 1909, for the selection of a successor to Sir Daniel Morris, the first Commissioner and head of the Imperial Department, the choice naturally fell upon Francis Watts. This early association with sugar is reflected in a number of papers published in association with Tempany on the chemical problems associated with sugar production. But his knowledge of the industry covered a much wider sphere. He held decided views on the sugar problems of the Empire, as is shown by his virile contribution to the discussion on the report on the production and consumption of sugar within the Empire presented at the conference organised in 1919 by the Society of Chemical Industry.

Until recent times, when oil has assumed major importance in Trinidad, the prosperity of the West Indies has been based on agriculture. Of the major crops, sugar has always been subjected to vicissitudes, and not the least of the functions of the Imperial Department of Agriculture has been the search for subsidiary crops. In this search Watts was not backward, as his studies on lemon grass, pawpaw, and so on, indicate. The Imperial Department established, in the *West Indian Bulletin*, its own organ, and in that *Bulletin* is to be found a record of these investigations. The *Bulletin*, in fact, constitutes a record of his activities.

As a result of the report of the Tropical Agricultural College Committee appointed by Lord Milner in 1919, the West Indian College was founded in 1921 and installed on a site, at St. Augustine, presented by the Government of Trinidad and Tobago. At the same time the headquarters of the Imperial Department was transferred from its former location in Barbados to Trinidad, and Sir Francis Watts, who had received the C.M.G. in 1904 and been created K.C.M.G. in 1917, was appointed to the post of principal of the College. From April 1, 1922, the two institutions were amalgamated under the title of the Imperial College of Tropical Agriculture, and the joint post of Principal of the College and Commissioner of Agriculture for the West Indies was held by him until his retirement in 1924. What part he played in bringing to fruition a scheme so dear to his heart is hidden away in the archives of the Colonial Office.

After his retirement Watts settled down in Trinidad and threw himself with all his accustomed energy, both as a member of the Legislative Council and as president of the Agricultural Society, into the affairs of the community. His last public service was to pay a visit to Mauritius, where he was sent as commissioner to report on the sugar industry of that island at the same time as Lord Olivier and Mr. D. M. Semple visited the West Indies on a like mission. His report was published in March last, and his death occurred shortly after his return to Trinidad.

H. M. LEAKE.

PROF. CORNELIO DOELTER.

ANOTHER prominent member of the brilliant school of Viennese mineralogists has passed away at an advanced age. Cornelio August Doelter, who died on Aug. 8 last, was born on Sept. 16, 1850, at Arroyo, Porto Rico, in the West Indies, where his father was a German planter and slave-owner, who had emigrated from Emmendingen in Baden. His mother, Francisca Cisterich, was Spanish, and on this account his name was sometimes given as Doelter y Cisterich. At the age of six he was taken to Paris, and he studied later at Freiburg in Baden, Heidelberg, and Vienna, graduating at Heidelberg in 1872. For a time from 1873 he was attached to the Austrian Geological Survey, and in 1875 was a *privat-dozent* in the University of Vienna. From 1876 until 1906 he was professor of mineralogy in the University of Graz in Styria, where in 1906 he was also Rector of the University. In 1907 he succeeded G. Tschermak as professor of mineralogy and petrography in the University of Vienna, from which post he retired with the title of emeritus professor in 1922.

Doelter's earlier papers from 1873 dealt with volcanic rocks, during which period he produced monographs on the volcanoes of the Ponza Islands, the Cape Verde Islands, and of southern Tyrol. From 1884 he did intensive work on the synthesis of minerals and rocks and on silicate fusions. At a later period he was much interested in the changes in colour produced by the action of radium, X-rays, and other radiations on gem-stones and other minerals; and he wrote several papers on the cause of the blue coloration of rock-salt.

Doelter wrote a number of books on chemical mineralogy, petrogenesis, precious stones, colour of minerals, and the mineral resources of the Balkans and Asia Minor; but his *magnum opus*, by which he will be best remembered, is his "Handbuch der Mineralchemie". This great work of reference (not entirely free from misprints) was commenced by him in 1911, after he had reached the age of sixty, and, although nine large volumes have appeared, it unfortunately remains uncompleted at his death. L. J. S.

Rev. J. G. Hagen, *S.J.*

Rev. Johann Georg Hagen, *S.J.*, who had been director of the Vatican Observatory for more than twenty years, died in a nursing home in Rome on Sept. 5, at the age of eighty-three years.

Father Hagen superintended the photography of the plates of the Astrographic Zone for declination N. 55° to 64°, which had already been commenced when he went to the Observatory. The University Observatory at Oxford helped in the reduction of the measures of these plates after the completion of its own section of the Astrographic Catalogue. He also gave much attention to the distribution of obscure nebulosity: he claimed to see this in many regions where photography failed to show it, and pointed out that some of the regions had been noted as nebulous by Sir W. Herschel. Many astronomers now admit the reality of at least some of the nebulosities announced by Hagen.

Father Hagen's name was already widely known before he went to the Vatican Observatory; more especially for his "Atlas stellarum variabilium", with its numerous appendices. This contained accurate charts of the fields surrounding the variable stars, with magnitudes of suitable comparison stars. It has been of great use to observers of these objects.

We regret to announce the following deaths:

Capt. William Colbeck, magnetic observer and cartographer with the Southern Cross Expedition to the Antarctic in 1898–99, on Oct. 19, aged fifty-nine years.

Mr. S. L. Hinde, formerly Commissioner of the East Africa Protectorate, who contributed to the ethnological, anthropological, and natural history collections of the British Museum, and was the author of "Fall of the Congo Arabs" and "The Last of the Masai", on Oct. 18, aged sixty-seven years.

M. Philippe Glangeaud, professor of geology in the University of Clermont, *correspondant* of the Section of Mineralogy of the Paris Academy of Sciences, author of works on the Massif Central of France, aged sixty-four years.

M. Emile Godlewski, honorary professor of agricultural chemistry in the University of Cracow and *correspondant* of the Section of Rural Economy of the Paris Academy of Sciences, known for his work on vegetable physiology, on Sept. 11, aged eighty-three years.

Mr. E. H. Wilson, Keeper of the Arnold Arboretum, Harvard, since 1927, known for his botanical explorations, on Oct. 15, aged fifty-four years.

News and Views.

Homage was paid to the memory of a great chemist, the late Prof. W. H. Perkin, by the Chemical Society at the first ordinary scientific meeting of the new session on Oct. 16, which was devoted to the acceptance and unveiling of a memorial plaque and the delivery of a memorial oration. The plaque, which (like the Harrison memorial) is the work of Mr. Ernest Gillick, is one of three; the others are destined to commemorate Prof. Perkin's distinguished association with the Universities of Manchester and Oxford. In presenting the plaque to the Society on behalf of the Perkin Memorial Fund Committee, Prof. R. Robinson said that the intention to offer suitable congratulations to Prof. Perkin on the attainment of his seventieth birthday had, to the immense regret of his colleagues, been frustrated by death, so that an occasion of joy had been changed into a memorial. It was fitting that the Chemical Society should possess a visible memorial of one who had served it so long and so well. Elected a fellow in 1884, he served on the council and as vice-president for several terms. He received the Longstaff medal in 1900, and was president from 1913 to 1915. Almost his last labour in the cause of chemistry was the delivery of the first Pedler lecture. The gift was unveiled by Mr. A. J. Greenaway, formerly editor of the Society's *Journal*, a life-long friend and at one time a colleague of Prof. Perkin; it was received on behalf of the Society by the president, Prof. J. F. Thorpe, who also paid tribute to the distinction of its late fellow and former president.

Prof. W. N. Haworth, responding to the president's invitation, delivered an oration on the late Prof. W. H. Perkin's life and work. Perkin's span of life was, he said, coextensive with the rise and development of modern structural chemistry. A pupil of Sir Edward Frankland, he studied also under the guidance of Wislicenus and afterwards of Baeyer, in whose laboratory he commenced his series of researches on the synthesis of closed carbon chains. Before he left this subject he had synthesised every naturally occurring monocyclic terpene, and had investigated the constitution of camphor and its analogues. On his return to Great Britain, he worked for a short time at Manchester on the natural colouring matters brazilin and hæmatoxylin before being appointed to a chair at the Heriot Watt College, Edinburgh, where he commenced his researches on berberine and cryptopine. Invited to occupy the chair of organic chemistry in Owens College, Manchester, in 1892, he built up there a great school of research, while at the same time giving much thought and care to his lectures. He combined exceptional skill in manipulation with sound judgment and acute observation; moreover, the help and encouragement which he gave to his pupils resulted in an *esprit de corps* and a personal loyalty which were the greatest incentive to good work and to progress in research. Of his period at Oxford from 1912 until 1929, Prof. Haworth said that Perkin's great work is appreciated by none more than by Oxford itself. William Henry Perkin consecrated

his ability and intellect to the ideal "that original research is in itself and by itself the most powerful weapon that ever can be wielded by mankind in struggling with the great problems which Nature offers on all sides for solution".

THAT the Church Congress, which recently met at Newport, should have devoted a session to the discussion of eugenics, is a sign of the times; and eugenists may congratulate themselves upon having moved public opinion to this extent. The Dean of St. Paul's (Dr. Inge), who read a paper on the subject, confined himself to its moral aspects. He urged that Church-people ought to include their duties to posterity among the new moral obligations which the advance of knowledge has laid upon them. There is still a weight of prejudice to be removed, and it is the mental attitude of Churchmen to these questions that he [illegible]ires to see modified. The desire to improve the intrinsic qualities of future generations, or to stop their further deterioration, is a purely disinterested and public-spirited quest. Is the Church to help these disinterested workers, or is it to ridicule and misrepresent them? The Dean expressed the view, held by all who have studied the subject, that a civilisation which gives its whole attention to environment, and pays no attention whatever to the inborn qualities of the children, is heading for disaster. He declared that there is dysgenic selection going on, the cumulative effects of which must result in progressive degeneracy. He thinks that the Church should not be indifferent to a system of *laissez-faire* which largely increases the number of criminals, fallen women, and others who prey upon society.

THE scientific aspects of eugenics were dealt with at the Church Congress by Dr. A. F. Tredgold, a member of the Consultative Council of the Eugenics Society. He said that while the amount of social inefficiency due to physical unfitness is very great, that due to mental unfitness is still greater and of even more importance. While a proportion of cases of both physical and mental unfitness are caused by faulty environment, the great bulk of such cases are a consequence of hereditary defects and are transmissible. On this point he thought that the eugenists have made out their claim, and that the prevention of propagation by these mentally and physically unfit individuals would result in an improvement of the race and a considerable decrease of social inefficiency. Dr. Tredgold observed that increased medical knowledge and facilities for treatment, humanitarian sentiment, and the general trend of social legislation combine to encourage the survival and propagation of the unfit, and to make life easier for them than for the fit. There are indications that the number and ratio of the inefficient and the unfit are increasing. If this process be allowed to continue, national degeneracy will only be a question of time and a sum in arithmetic. Partial interference by man in the shaping of his racial progress can only end in disaster; and Dr. Tredgold is of opinion that eugenics is not only necessary, but also the logical consequence of the steps which man has already taken.

AMONG the early scientific worthies buried in Westminster Abbey is the famous Dr. Isaac Barrow, scholar, mathematician, and divine, who was born in London in October 1630, three hundred years ago. The son of Thomas Barrow, linen-draper to Charles I., he was educated at the Charterhouse and Felsted, entered Peterhouse, Cambridge, and in 1649 became a fellow of Trinity. Finding the times unfavourable to churchmen, he devoted himself to medicine, botany, chemistry, geometry, astronomy, and poetry, and in 1656, at Constantinople, read all the works of St. Chrysostom. Home again in 1659, in 1660 he became professor of Greek at Cambridge, in 1662 professor of geometry at Gresham College, London, in 1663 was included in the first list of members of the Royal Society after receiving its charter, and in the same year became the first Lucasian professor of the mathematical sciences. This last post he resigned five years later in favour of his brilliant pupil Isaac Newton; but Barrow was afterwards made Master of Trinity College, the King declaring that he had bestowed the post "on the best scholar in Europe". Three years later, in 1675, he was chosen vice-chancellor of the University, and he died of fever on May 4, 1677, while on a visit to London.

BARROW'S mathematical works included his edition of the "Elements of Euclid", 1655; "Lectiones Mathematicæ", 1683; "Lectiones Opticæ et Geometricæ", 1669; and his edition of the "Conics of Apollonius", 1675. As a divine, Barrow ranked with the greatest of his age. Described as "a person of the lesser size, lean and of extraordinary strength, of a fair and calm complexion", a portrait of Barrow by Lefebre has long been included in the catalogue of the National Portrait Gallery, but this is not now considered genuine. The Gallery, however, possesses a pencil portrait by the contemporary artist Loggan. Barrow's death took place, one account says, "in a mean lodging at a saddler's near Charing Cross"; but Dean Stanley wrote that "He had come, as Master after Master had come, to the election of Westminster Scholars, and was lodged in one of the canonical houses that had a little stair to it out of the cloister, which made him call it 'a man's nest'. He was there struck with high fever, and died from the opium which, by a custom contracted when at Constantinople, he administered to himself." His grave in the Abbey is to be found on the west side of Poets' Corner, opposite to those of Chaucer, Browning, and Tennyson.

AFTER an interval of three years, a second Science Exhibition was held on Oct. 14–18 in the White Rock Pavilion at Hastings. This time the whole building was used, and the committee of local electricians, engineers, medical men, chemists, science teachers, artists, musicians, and others, with the mayor as president and the headmaster of the Grammar School as organising secretary, got together a much more comprehensive collection of working apparatus to illustrate modern scientific discovery and invention. Demonstrations were given every hour on such subjects as television, ultra-violet light, sound vibration, and electric transformers; cinematograph films were

shown to illustrate natural history subjects; and on successive evenings Sir Leonard Hill, Prof E. N. da C. Andrade, Prof. E. V. Appleton, and Dr. Alexander Wood lectured to considerable audiences on the advances in science with which they are especially familiar. Admission in the mornings was limited to parties of school pupils. It is obvious that in a town such as Hastings some means should be found for giving popular instruction in science, and the crowds that attended and the interest shown have convinced the promoters that the Exhibition has served this purpose. The receipts from admission fees will, it is expected, cover the expenses, so that no call on the guarantors will be necessary. One advantage of the Exhibition is that the scientific talent of the town has been mobilised to carry it out, and an enthusiastic band of workers brought together which will be available for other concerted efforts.

At a meeting of the Newcomen Society held at the Science Museum on Oct. 15, Mr. H. P. Vowles read a paper entitled "An Inquiry into Origins of the Windmill". Though our Domesday survey, made between 1080 and 1086, mentions between five and six thousand mills, it is presumed these were all water-mills or cattle-mills. The earliest authentic evidence of a windmill in England refers to that erected by Herbert, the Dean at Bury St. Edmunds, about A.D. 1191, the event being recorded in the "Chronicle of Jocelin de Brakelond". The question as to whence England and other western countries obtained their ideas of a windmill Mr. Vowles attempted to answer by recalling the travel and trade of a thousand years ago, when the Vikings sailed the waterways of Russia and a great trade route extended from Asia Minor through Persia to China. Near this trade route, as it passed through Persia, lay Sijistan, now Seistan, a land of almost ceaseless winds, where windmills were apparently in common use by the tenth century, and where innumerable windmills of a primitive type can be seen to-day. Mr. Vowles's paper contained many references to the manuscripts and early works he has examined, and what he calls "a not altogether unreasonable theory" of the origin of windmills is certainly worth pursuing.

The presidential address of Mr. L. St. L. Pendred to the Institution of Mechanical Engineers, delivered on Oct. 17, was entitled "Random Reflections" and was addressed principally to young engineers—"I mean", Mr. Pendred said, "men under forty". Great inventions have generally been made by men still under middle age, and it is often the ignorance of youth, disregarding any opinion but its own, which carries its will against the inertia age inevitably brings. No doubt it is right schools should say "It is so", but it is to be hoped there will be students with enough folly to try the apparently impossible. In our own time we have seen the theory of gravitation shaken, the theory of light in the melting-pot, and the transmutation of metals brought almost within reach. "It is a glorious age for those who would let their thoughts run free", but reasonable restraint should be used. Breadth of view is also desirable, and, as John Bourne said long ago, "an engineer must be content to believe that there are other things in the world besides cast-iron and steam pressure". The plea for a broader cultivation for engineers is seen in America, Germany, and France, as well as Great Britain. But with all this, while avoiding the evils of specialisation or what Johnson called the "drowsy equilibration of undetermined counsel", the present requires vigorous action, for, as Lytton said, "So much depends upon action, that everything seems to say aloud to every man: 'Do something—do it—do it!'"

An interesting paper on the operation of overhead power lines at 15,000 volts was read by M. Polack, the engineer of the Nord Lumière Co., at the recent International Union of Power Engineers at Paris. It is printed in the *Electrical Times* for Sept. 18. The overhead lines have a total length of 728 miles and are supported by concrete posts. Glass insulators are generally used, as it is found that they have a large factor of safety. The conductors are stranded and the network is supplied from the huge Gennevilliers Central Station. The principal causes of trouble are tempests, trees, birds, malicious persons, and deposits of conducting materials on the insulators. About 80 per cent of the disturbances are only for a few seconds. Of the remainder, which cause a shut down for a longer period, thunderstorms cause about ten per cent, birds about one per cent, and breakage of posts less than one per cent. Engineers fear thunderstorms most, as they affect the lines over a wide region and interrupt at the same time the telephone service. On wooden posts the lightning discharges make helicoidal grooves, cause arcs to be established between the conductor and distant objects, and destroy apparatus. The breaking of the wires is the most frequent result of a storm. The fall of trees sometimes breaks the wires, and the blowing of branches across the conductors starts arcs which weaken them. Both small and large birds can start an arc between a conductor and 'earth'. Accidents due to this cause are not uncommon in spring and autumn, but are rare in winter and summer. Even such small birds as starlings have been known to start an arc. Malicious and thoughtless people have been known to throw wires or old bicycle rims at the wires to see what would happen.

The quarterly meeting of the Grand Council of the British Empire Cancer Campaign was held at the new offices at 12 Grosvenor Crescent, Hyde Park Corner, London, S.W.1, on Oct. 13. On the recommendation of the Scientific Advisory Committee, a further grant of £150 was made to Dr. J. C. Mottram, pathologist at the Radium Institute, London; £300 to Mrs. E. K. Dawson, of Edinburgh, for the continuance of investigations into mammary cancer; and £250 to Mr. E. Nevill Willmer, at the Physiological Laboratory, University of Cambridge. An application for affiliation from the Natal Radium and Anti-Cancer Fund, South Africa, was received and acceded to, thus completing the representation of the British Empire Cancer Campaign either by way of branches or affiliated

bodies in every one of the British Dominions. It was announced that a popular book, entitled "The Truth about Cancer", has been finally approved by all the technical committees of the Campaign and will be published by Messrs. John Murray at a cost of 2*s*. 6*d*. per copy. The Campaign has fixed the price of the book at this figure so as to make it available for all classes of the community. The Campaign has received an intimation that a legacy of more than £20,000 will become available shortly for its research into the causes and cure of cancer.

On Oct. 19, Wing-Commander Kingsford Smith landed at Darwin, Northern Australia, having completed a flight from England to Australia in just over 10 days. His machine is an Avro Avian Sports model, driven by a 120-h.p. Gipsy engine, and its maximum fuel load is 100 gallons. It is thus a light aeroplane comparable with that used in February 1927 by Mr. Bert Hinkler, whose time for the same journey was 15½ days. Incidentally it may be noted that Kingsford Smith did the same journey last year in a three-engined Fokker, taking about 12 days. The daily stages of his recent flight were as follows: Rome (1000 miles); Athens (700 miles); Aleppo (1100 miles); Bushire (950 miles); Karachi (1050 miles); Allahabad (950 miles); Rangoon (1100 miles); Singapore (1200 miles); Sourabaya (1000 miles); Atambua (900 miles); Darwin (500 miles).

The Fifth Congress of Polish Physicists, held at Poznań on Sept. 24–27, attracted more than three hundred members. The Congress was divided into two sections, nearly equal in numbers—an educational section and a scientific one. The members of the latter section represented all centres of physical research in Poland, many of which were created after the recovery of the political independence of that country. The Congress was held under the presidency of Prof. M. Wolfke, of the Technical Institute, Warsaw. Seventy-two experimental and nine theoretical papers were presented, showing a considerable increase of scientific activity since the last Congress, held at Wilno in 1928. The Physical Institute of the University of Warsaw, the director of which is Prof. Pieńkowski, contributed more than twenty papers.

It is interesting to note that some fields of research seem particularly to attract Polish physicists. These are, with the number of papers in each: molecular and atomic spectra (35); dielectric constants (9); electric arc (8); radioactivity (6). Special interest was aroused by papers on association of light quanta, by Wolfke; allotropic modification of liquid ether, by Wolfke and Mazur—the first case of allotropy in the liquid state was discovered in 1928 by Wolfke and Keesom in liquefied helium; X-ray investigation of the structure of wood, by Pieńkowski; resonance spectra of silver and zinc vapours, by Kapuściński, Warsaw; absorption spectra of sulphur, selenium, and tellurium, several papers, University Institute, Warsaw; a mercury arc of extremely high efficiency, by Reczyński, Lwów; isotopic effect in band spectra, by Curtiss and Patkowski, Wilno; dielectric constants, by Zakrzewski, Kraków; Raman effect at critical temperature, by Ziemecki and Narkiewicz, Warsaw; ionisation potential of radon, by Holweck and Wertenstein, Warsaw. The Congress has elected Mme. Curie and Prof. W. Natanson as honorary members of the Polish Physical Society.

Lord D'Abernon has accepted the office of president of the National Institute of Industrial Psychology, in succession to the late Earl of Balfour, its first president. Lord D'Abernon, like his predecessor, is keenly interested in the activities of the Institutes, both industrial and educational. He is a strong advocate of the value and necessity of the better methods devised and employed by the Institute for giving advice to young persons in their choice of a career.

The Horace Brown Medal of the Institute of Brewing is awarded by the Council for "eminent services on the scientific or technical side of the fermentation industries, at intervals of not less than three years". The first award was made to Prof. H. E. Armstrong in 1926, and the next recipient of the medal is to be Dr. E. S. Beaven, who, by his individual work, has done more than anyone to add to our knowledge of barley. The presentation will be made by the president, Mr. Percy Gates, in the lecture theatre of the Institution of Electrical Engineers, on Friday, Nov. 21, at 8.15 P.M., when Dr. Beaven will deliver the memorial lecture on "The Culture of Barley for Brewing".

Dr. A. W. Hill, director of the Royal Botanic Gardens, Kew, leaves England on Oct. 24 on a visit to South Africa at the invitation of the Government of the Union. Dr. Hill will examine the botanical and allied activities of the Union under the guidance of Dr. I. B. Pole Evans, chief of the Division of Botany, Pretoria. The visit has been made possible by a grant from the Empire Marketing Board to Kew for overseas visits. Dr. Hill expects to leave Beira on Jan. 2 to go to Uganda (where he will be the guest of the governor) and to Kenya; in both colonies he will visit the agricultural and botanical departments. The tour will end with a visit to the East African Agricultural Research Station, Amani, to attend the conference of directors of agriculture at the end of January.

King Edward's Hospital Fund for London has arranged the following series of demonstration-lectures: "A Hundred Years of Photography", by Dr. Walter Clark, director of the Research Laboratories, Kodak, Ltd., on Oct. 29; "Sound-Reproduction", by Mr. J. H. A. Whitehouse, head of the Technical Publications Department of the Gramophone Co., Ltd., on Nov. 5; "The Miracle of Sound-Photography", by Mr. J. L. Underhill, chief recording engineer of the R.C.A. Photophone, Ltd., on Nov. 10; "Dyes and Dyeing", by Major F. A. Freeth, research manager of Imperial Chemical Industries, Ltd., on Nov. 19; "A Light Talk on Illumination", by Mr. T. E. Ritchie, chief illuminating engineer of the General Electric Co., Ltd. All these demonstrations will be given at the Portland Hall, Regent Street Polytechnic, at 5.30 P.M. A further demonstration, "The Romance of a Lump of Coal", by Sir Francis Goodenough, controller of gas sales of the Gas Light and Coke Co., will be given at 6 P.M. on Dec. 8 at the Caxton Hall, Westminster. The feature of the series

is that prominence is being given to practical demonstrations illustrating the development of the subjects. Tickets can be obtained from the Secretary, King Edward's Hospital Fund for London, 7 Walbrook, E.C.4, or at the doors, prices 2*s.* 6*d.* and 5*s.* (seats numbered and reserved) each demonstration, or 12*s.* 6*d.* and 25*s.* for the series.

IN the article referring to the meeting at Stockholm of the International Union of Geodesy and Geophysics, which appeared in NATURE for Oct. 11, p. 585, a statement appears suggesting that an Auroral Atlas is in preparation. We understand that this Atlas is, in fact, already prepared and published, and its distribution is now being undertaken by Prof. C. Stormer, chairman of the Committee responsible for its preparation.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A lecturer in civil engineering at Armstrong College—The Registrar, Armstrong College, Newcastle-upon-Tyne (Nov. 1). A plant physiologist at the Agricultural and Horticultural Research Station, Long Ashton, Bristol—The Secretary, University, Bristol (Nov. 3). An assistant pathologist at the French Hospital and Dispensary, Shaftesbury Avenue—The Secretary, French Hospital and Dispensary, 172 Shaftesbury Avenue, W.C.2 (Nov. 4). An assistant pathologist to the Pathological, Bacteriological, and Clinical Research Department of the Royal Sussex County Hospital, Brighton—The Secretary-Superintendent, Royal Sussex County Hospital, Brighton (Nov. 10). A senior assistant pathologist at the Auckland Hospital—The Secretary, Auckland Hospital Board, Auckland, New Zealand (Dec. 15). A part-time master for electrical engineering at the Technical Institute, Ponders End, Enfield—F. G. Apthorpe, Education Offices, Gentleman's Row, Enfield.

Our Astronomical Column.

Magnetic Disturbance and Aurora.—A magnetic disturbance, classified as a 'small storm', commenced at 15h G.M.T. on Oct. 17 and lasted about ten hours. The range in declination at Greenwich was 55′, the oscillations of the needles being most rapid about 17h and 22h. There was an accompanying display of the aurora borealis, which seems to have been particularly well seen from the eastern counties of England. Mr. Charles Leaf, 7 Grange Road, Cambridge, states that at "1952 G.M.T. a low arch was visible stretching from north-west through north to north-north-east. This was bright green in colour, the lower edge being quite sharply defined, while the upper edge gradually merged into the clear sky above. At its highest point the arch was perhaps 15° above the horizon, and the extremities did not quite reach it. No streamers were observed." The arch persisted until 2130 G.M.T., when rainclouds finally hid it. Mr. H. W. L. Absalom, 9 Hillside Gardens, Wallington, Surrey, saw an auroral display between 6.30 and 6.45 P.M. (G.M.T.). "The phenomenon was first a comparatively short, thin, and rather diffuse arc of glow a few degrees below the three most westerly stars of the Plough. A few minutes later vertical structure became apparent, there being meanwhile a slow westward drift of the phenomenon, which, in its final form, seemed to consist of a nearly vertical shaft to the north-west. This shaft faded somewhat suddenly a minute or two before 6.45 P.M."

At this time there was a relatively small group of sunspots about two days' travel past the sun's central meridian. This group, seemingly unimportant, was more interesting spectroscopically; it was surrounded by a conspicuous area of bright hydrogen flocculi, and as another index of activity, small but fairly rapidly moving streams of hydrogen, shown as absorption markings, were associated with the rearmost spot on Oct. 18 and 19. Whilst in these respects alone the group of spots was not unusual, the region may be considered at least as suspect in a possible association with this magnetic disturbance and aurora.

Bright Lines in Long-period Variable Stars.—An examination of the behaviour of bright lines in the spectra of long-period variable stars is made by Merrill and Burwell in the *Astrophysical Journal*, vol. 71, p. 285. The wave-lengths of 58 bright lines are recorded originating in hydrogen, iron (including 'forbidden' lines), magnesium, silicon, manganese, and (doubtfully) strontium and iridium. The forbidden iron lines and a magnesium triplet in the ultra-violet have not previously been recorded. The most interesting results deal with line intensities. Intensity *ratios* rather than absolute values are used, in order to avoid photometric difficulties, and the ratio $H\gamma : H\delta$ shows striking variations throughout the light-period which are common to all the *Me* type stars examined. It rises rapidly from 1/8 up to 1/2 (reaching the latter value just before the maximum light-phase), then remains nearly constant for more than a fifth of the period, and finally rises rapidly again to about 5/2. Other intensity ratios show similar variations. The results are discussed, and it is shown that the bright lines behave as if they had little dependence upon the photosphere. It is also suggested that the band-producing titanium oxide exists at a higher level than that at which the bright lines are produced.

Pluto.—Mr. Bower has compared the recent observations of Pluto made by Prof. G. van Biesbroeck at the Yerkes Observatory with the ephemeris prepared by himself and Mr. Whipple using the elements that they derived from observations extending from 1919 to 1930. The mean correction to the ephemeris at the beginning of September last is only −0·3″ in R.A. and 0·2″ in Decl. This is so small that it finally clinches the correct identification of the 1919 images with Pluto. This was really quite certain already, but some astronomers preferred to wait for the autumn observations before accepting them; these should now be satisfied.

M. F. Quenisset succeeded in photographing Pluto at the Juvisy Observatory on Sept. 25, using a lens of only 5 in. aperture and 24 in. focal length. The exposure was for 2¼ hours. He estimates the magnitude as 15; Prof. Wolf thought it somewhat brighter than this; probably something depends on the type of plate used, as the light of Pluto appears to be yellowish. It is now near its stationary point, and will soon begin to retrograde. Messrs. Bower and Whipple have issued an appeal to all who have access to old plates that might contain images of Pluto to examine them carefully. They gave an ephemeris for past years in *Lick Observatory Bulletin*, No. 427. This is so near the truth that only a small region on each plate would need to be scrutinised. Two plates of each region are needed to distinguish the planet from a star, unless the exposure is so long that the planet has trailed appreciably.

Research Items.

A Survival in Sind.—Mr. Ernest Mackay, in the *Journal of the Royal Anthropological Institute*, vol. 60, pt. 1, in describing the pottery-making industry of Balreji village, two miles south-east of the ancient site of Mohenjo-daro, singles out a number of details in which he sees resemblances to the pottery of the ancient East and particularly to the painted pottery of Sumeria. The wheel is unlike that employed anywhere else in India except in the upper Punjab, having two discs, of which the lower is turned by the foot. The foot wheel is used in the Bahrein Islands and elsewhere in the Persian Gulf, whence it may have reached India either overland or by sea. In making small vessels a tall column is moulded from which the completed vessel is severed by a cord. This leaves a characteristic groove in the base. Similar grooves are to be detected in Sumerian and Mohenjo-daro pottery. Vessels were cut from the wheel by cord in Crete so early as Middle Minoan II. The larger jars are built up in three or four parts on a moulded base. The same method, except for the moulded base, is found in pottery of the pre-Sargonic period of Mesopotamia and in the painted pottery of Jemdet Nasr near Kish, *c.* 3500 B.C. The method of tapping the pottery before quite dry with a block and spatula may have been employed in the manufacture of some of the so-called hand-made pottery of the early East. Specimens of the tapping block have been found at Harappa and various sites in Northern Baluchistan. To decorate the pots, they are placed on a conical stand and a cover with a projecting knob is placed in the mouth of the pot, this being used to revolve the vessel with the palm of the hand. Similar covers are found at Mohenjo-daro and also at Jemdet Nasr. Though the designs show very little resemblance to those of Mohenjo-daro, except that the scale pattern of the Nal pottery may be attributed to the influence of the Indus valley culture, yet the very survival of the art may itself be due to a tradition handed down from the people of Mohenjo-daro rather than to a new introduction. It is certainly not Greek or Arab.

Characteristics of the Peoples of Central Asia.—During a long sojourn in Central Asia (1892–1908) J. Talko-Hryncewicz collected many skulls of the present-day and former inhabitants, which he found by the railways and in fields, forests, and cemeteries. Their abundance was due to the belief of the Buddhists that the most honourable sepulchre was in the interior of wild beasts, and to the consequent scanty burial given to corpses. A study of the skulls shows that the population is composed of two principal types (*Bull. intern. Acad. Polonaise Sc. Lett.*, Ser. B, p. 107, 1930). The first type, Mongolian and contemporaneous, comprises two varieties, an eastern and a western, the latter perhaps mingled with Turks. The second type, represented by a probably pure Turkish race, is extinct at the present day, the remains being found only in tombs. This 'Euro-Asiatic' race, which mixed with others, such as the Mongols, was once very numerous and had several branches. It spread even to the bounds of central Asia on the north-east, and its influence upon the Chinese there is marked by the presence of carriage roads, irrigation canals, and certain agricultural implements, while its rune-like inscriptions remain on the stone tombs of the Khans at Karakoram. The author believes that the characters of the skulls and the size and development of the skeleton indicate that this is the race to which the Huns belonged, and accordingly he does not hesitate to range the Huns as a race with Turkish rather than of Finno-Mongol with Slav affinities.

Birds of the Antarctic Seas.—The British Antarctic Expedition of 1910 on the *Terra Nova* made a collection, amongst other things, of bird skins, but the accidents of death, first of Dr. E. A. Wilson, the naturalist of the Expedition, and then of Mr. Ogilvie-Grant, have delayed the report until now. A casual glance at the report suggests that it is largely due to the pen and pencil of Dr. Wilson, and, indeed, its text and the many drawings in pencil and colour reflect the keen observation and skill of that ill-fated naturalist. But closer reading shows that the authors, Dr. P. R. Lowe and N. B. Kinnear, have contributed a great deal to the scientific value of the work, notably by their long series of measurements of specimens from different regions, and by their remarks on age and locality differences. Forty species and sub-species were observed and obtained during the voyage, and many interesting notes on habits, characteristic attitudes in flight and in feeding were made. One of the most striking was the observation near Cape Crozier that young and adult individuals of the Emperor penguin were frozen into the lower layers of the old bay-ice of the previous winter and dropped into the sea as the ice melted. That and the presence of adults with chicks of different stages, seen at various places from Dec. 19 until Jan. 4, confirmed the suspicions that the chick is very slow in shedding its first plumage and the egg has to be laid and hatched out during the winter months.

Swarming of Bees.—In an article on the phylogeny, physiology, and biology of the swarming of bees (*Biol. Zentralbl.*, Leipzig, Bd. 50, p. 219; 1930), G. Gotze discusses the investigations made on this subject at the Institute of Plant Diseases at Landsberg. Swarming, he holds, originates as a rule owing to lack of room, lack of food, or the unsafe condition of the old nest, and not, as Edwards and Latham have stated, as part of the nuptial flight. It is a division of the bee-stock in which the sex-impulse has no part, and most likely arises from an instinct impelling to migration towards favourable conditions of food and colonisation. It is an expression of the social relationship between the queen and her subjects, an election flight which leads to the division of the bee-stock as soon as several females have come to adult state. The social problem amongst bees has found, in different quarters of the globe, three types of solution. In America the stingless *Meliponi* exhibit the flight of young queens with partial swarming; in India the workers of *Apis dorsata* build new nests and this is followed by the swarming of the queen; and in Europe, the old queen of *Apis mellifica* flies off, and later there follow successive swarms with young queens. The author considers that such harmonious procedure as swarming in a state composed of so many castes could not be due to physiological reflexes to particular stimuli, and favours the view that a deep-seated hereditary instinct is involved.

Regeneration and Normal Growth.—Przibram's measurements of *Sphodromantis* and those of Křizenecky on *Tenebrio* reached analogous conclusions that a parallelism exists between regenerative and normal growth. Ubisch, on the other hand, regards differentiation, not growth, as the essential feature of regeneration. E. Godlewski and J. Latinik have attacked the problem afresh by determining during ontogenesis and during regeneration the growth of sectors of the tail of axolotl, the segments being so

far as possible equal and placed behind each other (*Bull. intern. Acad. Polonaise Sc. Lett.*, Ser. B, p. 79, 1930). The authors share neither of the opinions indicated above, for they regard growth and differentiation as complex general notions, indicating the resultant of several very different factors. Growth can indeed be distinguished in the ontogenetic and in the regenerative phase: in the former it is uniform in all the sectors; in the latter, apart from a generally accelerated movement, it shows stronger growth in the anterior than in the posterior sectors. It would appear, therefore, that factors take part in regeneration different from those involved in normal growth, and that a theory which limits regeneration to accelerated growth does not fully meet the facts of the case.

Graft Hybrids.—A valuable account of investigations in this interesting field is given by Prof. F. E. Weiss in *Biological Reviews*, vol. 5, No. 3, 1930. After some discussion of the vexed question of the influence of stock on scion, a very succinct historical account is given of the best known horticultural 'sports' which are now interpreted as graft hybrids, namely, the bizzarria orange, *Cytisus Adami*, and *Crataegomespilus*. In the last case, Weiss and Haberlandt regard the explanation of this plant as a periclinal chimæra as in doubt, because the shape of the epidermal cells, as seen in surface view, does not correspond with that of either of the original plants, from the graft union of which the sport has apparently arisen. It is not clear, however, why the authors should expect an epidermal cell to retain all its original characteristics of shape when it is subjected to a different amount of superficial extension, due to the fact that it is now spread over a core of different growth capacity. Baur's original explanation of some of these graft hybrids as chimæras, in which a skin of one parent is spread over the core of another, has been fully confirmed by the beautiful experiments in the artificial production of such graft hybrids from the region of graft union, which were initiated by Winkler. Prof. Weiss describes these experiments and shows how the further elucidation of the complex phenomena associated with the production of graft hybrids depends upon adequate cytological studies, and upon the developmental studies of the growth processes in the apical meristem. Many cases of graft hybrids have been brought under notice because the tissues from different parents show different capacities in the production of green chloroplasts. Prof. Weiss makes it clear, however, that the interpretation of the genetic and somatic factors involved in the production of variegation is a very complex and involved problem.

Land Mollusca from Caribbean Islands.—Visits during the expedition of the yacht *Mary Pinchot* were paid and land mollusca collected at Grand Cayman, the Swan Islands, Old Providence Island, and St. Andrew Island, the results of which are now described in full by Dr. H. A. Pilsbry (*Proc. Acad. Nat. Sci. Philad.*, vol. 82). Some work had previously been done on the land mollusca of Grand Cayman and the Swan Islands, but no land snails have hitherto been reported from Old Providence or St. Andrew Islands. Of the twenty-nine species collected at Grand Cayman, nineteen are restricted to it, and the author considers that it has existed well back into Tertiary times and has never been connected with Cuba. Its fauna can be most credibly accounted for by a former land connexion with Jamaica. Twenty-two species of land snails are now known from the Swan Islands, of which nine are special thereto. Sceptical as to the ability of land snails to make long sea voyages, Dr. Pilsbry regards their origin as obscure. The ridge on which Old Providence and St. Andrew Islands stand was formerly emergent and connected with the mainland, probably in Pliocene times.

Metamorphism and Geological Structure.—In an important paper by Gertrude L. Elles and C. E. Tilley, published in the *Trans. Roy. Soc. Edinburgh* (Vol. 56, Pt. 3, No. 25, 1930), the results are presented of many years' work on the structure of the Central and Southwest Highlands as shown by the metamorphic condition of the beds. In addition to very extensive field work, nearly 3000 rock specimens have been sectioned and examined in order to define with precision the limits of the various metamorphic zones that have been recognised. The distribution of the latter shows very conclusively that the fundamental structure of the entire region was one of large-scale recumbent folding of the type suggested by Bailey. The connexion between this folding and the metamorphism is so close that the two processes must be regarded as having taken place approximately at the same time. The early recumbent folding was followed by a simpler type of folding like that found in the southern uplands. This stage was unaccompanied by constructive metamorphism. The movement seems to have culminated in the development of a series of thrusts with an overdrive to the north-west. The impulse of the earlier folding, however, appears to have come from the north-west. The two sets of trend lines are not exactly parallel. The paper is well illustrated with maps and sections, and is a most valuable contribution to our rapidly growing knowledge of an area and a method in both of which Barrow was the pioneer.

Australian Rainfall.—The Commonwealth Meteorologist has produced the rain map of Australia for 1929. Twelve small maps show the monthly rainfall and a large one the annual rainfall. The maps are based on the record of 1300 stations that are well distributed except for a gap in the interior of the western half of Australia. Only fifteen per cent of the country had rain in excess of normal. This compares with thirteen per cent last year, but this year was really worse, because there were very dry conditions in the pastoral lands of South Australia, northwest of New South Wales, and south-west Queensland. In some of those areas the totals were the lowest on record. The wheat areas of Victoria had a lack of rain during the critical winter and spring months. The total wheat harvest of Australia has been estimated to have dropped from 160 million bushels last year to 126 million bushels. Wool production, however, was high, and the sugar plantations do not appear to have suffered from shortage of rain. Tasmania as usual had a good rainfall.

Ultra-violet Glazing.—In response to the frequent inquiries from the building industry as to the use of window glasses transparent to ultra-violet rays, the Building Research Board of the Department of Scientific and Industrial Research has issued a *Bulletin* of a dozen pages on the subject, prepared by Mr. H. E. Beckett. A number of glasses which, when in sheets of 0·23 cm. thickness, transmit 65 per cent of the therapeutic rays between 0·29 and $0{\cdot}32 \times 10^{-4}$ cm. are now available, but their transparency falls off to 55 per cent in the course of three months' exposure to sunlight, and any dirt which may collect on their surfaces reduces their transmission still more. To get the therapeutic benefit of a window of the glass, it is necessary to sit within a few feet of it, as the available radiation falls off rapidly with increasing distance from the window, and at most points within a room the amount available is small. Copies of the *Bulletin* can be obtained from H.M. Stationery Office (price 4*d.*).

Possibility of Collisions between Light Quanta.—If light has a corpuscular structure, collision phenomena might be expected to occur when two beams cross each other, and it would be possible, for example, for two similar quanta to give rise to a new one of a new frequency. A search for an effect of this nature is described by A. L. Hughes and G. E. M. Jauncey in the second August number of the *Physical Review*. Two beams of sunlight, filtered through red glass, were passed through a pair of large lenses, so that the beams, the axes of which were inclined at 120°, intersected at a common focus. The point of intersection, when examined through a green filter with a dark-adapted eye, showed no detectable light, and it is calculated, from the energy of sunlight and the sensitivity of the eye, that the collision area of the quantum, for an event of this type, is less than 3×10^{-20} cm.^{2}

Protecting Transmission Lines from Lightning.—During a severe thunderstorm the engineers of overhead transmission lines have an anxious time. They do not fear that the surges set up in the lines may do damage, as modern lightning arresters are very efficient; but they do fear, however, that direct flashes of lightning may strike the line. In *AEG Progress* for October the methods of protecting transmission lines from direct strokes are discussed. It is suggested that if all the lattice towers are connected with the earth through a suitable resistance and are connected together by an earth wire, then the line will be practically safeguarded. The author states that a lightning flash is non-oscillatory and a cathode ray oscillogram is shown to support this statement. A description is given of experiments carried out in the A.E.G. high tension laboratory to find the nature of the canal through which a high tension discharge takes place in air. Currents were varied from 1500 to 60,000 amperes. The diameter of the spark canal was measured photographically, every precaution being taken to prevent irradiation on the photographic plates. A curve is given to show the relation between the diameter of the spark canal and the maximum current. The record shows that with high discharge currents, the current density in the spark canal approximates to a constant value of ten amperes per square millimetre. A lightning current of 175,000 amperes would thus require a canal of diameter 15 centimetres. The spark canal in the experiments was constricted at the points where it started and finished. Similar constriction should occur when lightning flashes hit the ground. The author considers that a fulgurite of 5 centimetres diameter would be caused by a lightning flash of 175,000 amperes.

A New Distance Finder.—To meet the increasing need for a simple and inexpensive apparatus for measuring distances, Messrs. W. H. Harling, Ltd., of 117 Moorgate, E.C.3, have just introduced a "Popular Distance Finder" (price 27s. 6d. without staff: staff, 7s. 6d. extra), which should be of use to surveyors, engineers, architects, scouts, etc. The size of the instrument when set up is 12½ in. × 10 in., and, without the staff, packs up to 12½ in. × 2½ in. × 2½ in. It consists of a horizontal arm carrying a cross-bar and scale at one end and an eye-piece at the other, mounted on a staff. The scale arm is also provided with eye-pieces for observations along the chosen base-line. Two adjusting slow-motion gears are attached, one to turn the whole instrument about the staff, the other to turn the scale arm only. Each arm is fitted with a spirit level, and the scale is so graduated that, if the length of the base-line is 10 or 100 units, the required range may be read off the scale without calculation. Another feature in the simplicity of the design lies in the fact that there is no restriction as to the direction of the base chosen. Provision is made for reclamping the instrument on the staff in a vertical plane, so that heights may be as readily measured as horizontal ranges. Any distance from 50 feet to 5 miles may be measured; indeed, the range is limited only by visibility and the power of the eye, and, provided the base-line is not less than one-tenth of the distance to be measured, a 99 per cent accuracy is obtainable.

Sodium Vapour.—Measurements of the vapour pressure and density of sodium by Rodebush and Walters are described in the July number of the *Journal of the American Chemical Society*, from which the authors conclude that there can be no question of the existence of an appreciable amount of Na_2 molecules in the vapour. This conclusion is of interest in confirming the results of band spectra, which also indicate the presence of double molecules in the vapours of alkali metals, previously regarded as purely monatomic.

Rapid Estimation of Copper.—In the September issue of the *Berichte der Deutschen Chemischen Gesellschaft*, Prof. Fritz Ephraim describes some remarkable results which he has obtained in estimations of copper both in pure salts and in the presence of many other metals by means of the co-ordinated complex derivative which the metal forms with salicylaldoxime. The sensitiveness of this reagent is said to be greater than that of dimethyl-glyoxime for nickel. Moreover, it gives much more satisfactory results than cupron (benzoïn oxime), since it can be used in the presence of dilute acid, when its action becomes highly selective, the corresponding compounds with all other metals being held in solution. It is important to eliminate by careful washing all traces of excess of the reagent, otherwise the precipitate may decompose on drying. The dry compound contains nearly 19 per cent of copper and can be weighed accurately on a Gooch crucible.

Melting Points of Krypton and Xenon.—The melting points of the inert gases krypton and xenon have been redetermined by Dr. Kurt Peters and Kurt Weil (*Zeitschrift für physikalische Chemie*, Abt. A, Bd. 148, Heft 1/2). The essential part of the apparatus is a glass tube 4 mm. in diameter slightly bulbed at the lower end. Within this slides a glass rod, 2 mm. thick and 10 cm. long; the lower end of the rod has three slight projections. Also included is an iron tube surrounding the glass rod and allowing this rod to be moved up or down with the help of an external electro-magnet. By means of liquid air the inert gas is condensed as a frozen ring in the lower part of the outer tube. With the help of the magnet the lower jagged end of the rod is set into this frozen ring. The whole apparatus is then introduced into an aluminium block thermostat, and the tip of the rod is watched by means of its projection on a screen whilst the slowly rising temperature is determined on a platinum resistance thermometer. The results obtained for the melting points of krypton and xenon are $-157{\cdot}0° \pm 0{\cdot}5°$ C. and $-112{\cdot}0° \pm 0{\cdot}5°$ C. respectively. Since these results differ considerably from those of Ramsay and Travers, it seemed desirable to control the figures by time vapour pressure curves. A bend in the curves confirms the temperatures given. The normal boiling points were also determined by extrapolation. In a separate paper, "Adsorptionsversuche mit schweren Edelgasen" (*Zeitschrift für physikalische Chemie*, Abt. A. 148 Bd. 1/2 Heft), the same authors have described a method for the quantitative separation of argon, krypton, and xenon. The mixed gases can be adsorbed on carbon at $-190°$ C., and then as the temperature rises they can be 'desorbed' through separate successive ranges of temperature by means of a mercury pump.

New Science Buildings at Christ's Hospital, Horsham.

HIS Royal Highness the Prince of Wales, who is the president of Christ's Hospital, visited the school at Horsham, on Oct. 14, to open the new buildings (Fig. 1) which have recently been erected for the purpose of supplying increased facilities for the teaching of science and geography.

The Prince arrived by aeroplane about mid-day and, accompanied by the headmaster and the Bishop of Worcester, he entered the new quadrangle, where he addressed the assembled school. In the course of his speech, he thanked those who had subscribed to the building fund and stressed the importance of biological and geographical studies in furthering the welfare of the Empire.

"The new building," he said, "which adds so finely to the beauty and usefulness of this great and ancient school, is to be used mainly for the teaching of geography and of natural sciences, among which, I understand, biology will now be able to take its proper place beside chemistry and physics. Knowing as I do the need of scientific investigators to fill posts in outlying parts of the Empire, the teaching of geography and biology has for me a special appeal. They are both Imperial subjects, and they both make for the better understanding of mankind. To appreciate, through a study of biology, both the variety and the unity of all organic life is the surest path to sympathy and sound philosophy." The Prince then declared the building open and made a tour of inspection through it.

The new block of buildings is of red and white stone and forms the east side of a new quadrangle. It is very substantially built: the walls are double and the space between them filled with 'Hygean' rock—a material of bituminous nature—and the floors are of reinforced concrete.

On the ground floor are six large rooms. One is a chemical laboratory for the use of the more advanced students, leading out of which is a science library and reading-room. Two rooms are arranged for the teaching of practical mathematics, and one is a large biological laboratory. This is fitted with working benches and standing benches for aquaria, etc., and is intended for the more elementary work and nature study. It will be available for use out of school hours and will thus help to encourage the intelligent study of outdoor life, which has always been one of the aims of the school.

FIG. 1.—New science buildings, Christ's Hospital. West elevation and quadrangle.

On the upper floor are two large geography class-rooms. They are lofty and well lighted and have been excellently equipped under the direction of Mr. T. K. M. Booth, who is well known for his work as a teacher of physical geography. On this floor are also two other laboratories for more advanced biological work and a lecture room to accommodate about eighty boys. This is fitted with raised tiers of benches and is well equipped with up-to-date projection apparatus. Communicating with this by means of a hatch is a small preparation room.

Above one of the biological rooms is a flat roof, surrounded by a coping, where many outdoor experiments may be carried out.

The working benches in all the science rooms are of the knee-hole type, and each working space is supplied with gas, water, and both high and low tension electrical points. The constructional work has been carried out by Messrs. Henry Norris and Son, Ltd., of Hertford, under the direction of the architect, Mr. S. Tatchell, F.R.I.B.A.

Native Races of the British Empire.

THE first of the series of popular lectures under the auspices of the Royal Anthropological Institute in the coming winter took place at the Portland Hall of the Regent Street Polytechnic Annexe on Oct. 15, when Prof. John L. Myres, president of the Royal Anthropological Institute, delivered the inaugural lecture, on "Native Races of the Empire: Facts and Problems". He said that it is remarkable, and also natural, that the greater advances in the 'study of man' have occurred during the greater periods of exploration and exploitation. Contact and conflict with alien cultures sharpen men's observation of customs and beliefs, and provoke curiosity about the reasons for them. Political theories have been founded on travellers' tales about men in the 'state of Nature' presupposed by philosophers, and have differed like the customs so described. This has been the contribution of adventurers and administrators to anthropology. What has anthropology to offer in return by way of instruction, advice, or warning to those whose interests or duties involve intercourse with 'native races'?

At first sight, a survey of the native races of the Empire would seem to fall little short of a general survey of mankind, so widespread are the regions included. But the same reasons which explain the special courses taken by colonisation and conquest determined also which races and peoples the pioneers would encounter, the historical order in which they met them, and consequently the fund of previous experience with which each fresh 'native question' was handled. This in turn suggests a natural order in which to group studies of 'native races', according to their geographical backgrounds and economic foundations.

In North America, where intercourse between European settlers and aboriginals occurred first on a large

scale, it was mainly between hunters on both sides in the north, and only further south between hunting natives and immigrant farmers, involving transference of lands and displacement of natives by immigrants, eventually almost complete. Clash between the Plains Indians, already using the horse, and white cattle-ranchers, came later and was more severe; and in turn the discovery that grain could be grown on prairie restricted surviving redskins to a few limited reserves. In the mountain belt, displacement has been slower, as in the austerer north; and on the Pacific coast, fisheries and other local industries permit gradual incorporation of natives into the white community. All through North America, the absence of strong racial contrasts and the high quality of redskin intelligence has made absorption easy.

Contrast the course of events in Australia, where the physical difference was conspicuous, native adaptability was low, and the settlers' outlook, for various reasons, less favourable to tolerant or even humane intercourse. The dependence of Australian settlement on grazing animals emphasised the clash between pastoral and hunting populations; and the early discovery of precious metals introduced severe economic complications, unfavourable (as in South Africa) to aboriginal prosperity.

The natural poverty of aboriginal Australia contrasts alike with the natural wealth of New Zealand and of the Pacific island-world whence the Maori had come; and the higher intellectual endowment of the Polynesian helps to explain both the sturdy resistance of the Maori and the facility with which European intercourse has broken up the receptive culture of the other islanders. In Polynesia, and still more in Indonesia, tropical conditions (especially wealth of forest products) have on one hand precluded colonisation, and on the other led to various ways of utilising the forest-bred aboriginals as mere collectors of raw material, such as rubber or copra, under servile conditions which are disorganising their societies. Quite of a different kind are the problems which occur when the native population has domestic animals and is more or less pastoral and nomad, as in Arabia and Iraq, while the immigrants are agricultural and sedentary, or European needs favour agricultural elements against the pastoral. It makes little difference, moreover, to herdsmen, tenacious though they are of their own traditions, whether their grasslands have always been grazed, as in Arabia and Upper Mesopotamia, or were formerly the granary of great civilisations, as in Babylonia, Syria, Palestine, and Egypt. In northern Nigeria, the same clash of pastorals and cultivators appears in similar open country; and on the north-west frontier of India, too, the men of the plains are cultivators and the hillmen mainly pastoral, though not nomad like the Arabs and other Moslem pastorals.

As the only regions within the Empire or its mandated territories where purely pastoral communities are predominant lie where normal European colonisation is not practicable, contact with nomad peoples would be limited to marginal police work; were it not, with modern agricultural and engineering methods it is possible to farm large tracts of grassland, so that customary pastures are abridged, and nomads raid cultivated lands in reprisal.

In Palestine, for special reasons, political and sentimental, a country long abandoned to immigrants still mainly nomad is being reoccupied by sedentary farming communities, supplying the needs of an even larger tour-population, also immigrant, and imperfectly accustomed to traditional modes of life.

It is necessary to take account of the special problems of contact with pastoral peoples, as well as with hunting tribes and with the simpler cultivators, if we are to understand the peculiarly complicated situation all down eastern and southern Africa, from Sudan to the Kalahari Desert. Here, moreover, mainly because these tribes, so long as they kept to the plateaux, seldom wholly lost their cattle, and consequently kept their mobility, the population is unstable and tends to drift southward, gently or violently, with overlaps, conquests, and race mixture. Into this initial confusion European exploitation, based on the coasts, brings into the interior numerous cross-currents and such complication as former Arab slave-raiding, recent devastation of cattle and peoples by fly-borne and travel-borne diseases, the shift of native labour into gold-fields and diamond-fields, and the wastage of brains and resources in the so-called 'scramble for Africa' between Europeans.

Subsequent lectures will deal, on Nov. 12, with "Spirit Worshippers of the South Seas", by Mr. A. M. Hocart; on Dec. 10 with "Tribes of the Egyptian Sudan", by Lord Raglan; and after Christmas, with other native races, to be announced later.

Photosynthesis of Carbohydrates.*

As has already been described in previous papers, the photosynthesis of carbohydrates can be achieved by the irradiation of carbonic acid absorbed on a suitable surface in the form of a very fine powder. The material used in the earlier experiments was nickel carbonate, which, however, required previous activation by means of light and was only effective for about two hours.

Considerable advantage is gained by the use of ferric oxide as catalyst, the oxide, containing some thorium oxide as promoter, being deposited on kieselguhr which has previously been coated with aluminium hydroxide. The aluminated kieselguhr is evaporated to dryness with a solution of ferric nitrate, and the product is first ignited in a stream of dry air and afterwards heated at 410° in a vacuum in order to remove any adsorbed nitric oxide. These powders do not require any previous activation.

The activity of the powders in promoting photosynthesis varies in a remarkable way with the amount of thorium oxide present in the ferric oxide, sharp maxima being observed when the thorium oxide content is about 1·31 and 2·12 per cent with minima on either side of these amounts. The maximum yield of carbohydrates is about 0·13 gm. per hour with 100 grams of powder at 18°.

It has been found that photosynthetic activity is proportional to the magnitude of the electropositive charge assumed by the powders when in suspension in water saturated with carbon dioxide. This enables the activity of any powder to be rapidly determined. The most active powders give in the cataphoresis apparatus a velocity of 0·00041 cm. per second along a potential gradient of 1 volt per cm. Cataphoresis measurements made with activated nickel carbonate have shown that the material completely loses its activity in two hours when its suspension in conductivity water is exposed to light. The short-lived activity of this substance as a catalyst for the photosynthetic reaction is thus explained.

Cataphoresis measurements have rendered possible the determination of the rates of the poisoning of the

* Substance of a paper read by Prof. E. C. C. Baly, F.R.S., before Section B (Chemistry) of the British Association at Bristol on Sept. 8.

powders by the oxygen produced in the photosynthetic reaction and of the subsequent de-poisoning by carbonic acid. The ferric oxide powders in suspension in water saturated with carbonic dioxide maintain a constant cataphoretic velocity when kept in the dark. A suspension of a powder, with a stream of carbon dioxide passing through it, becomes less electropositively charged when exposed to light, the decrease in charge depending directly on the intensity of the light. When the intensity of the light exceeds a definite value the powder undergoes complete flocculation and is rapidly deposited on the bottom of the containing vessel. If the irradiation is then stopped, the powder is de-flocculated and the original maximum electropositive charge is restored, the poisoning and depoisoning being completely reversible. It follows from this that if the intensity of the light be not too great the photosynthetic production of carbohydrates becomes a continuous process.

It has been previously shown that the yield of carbohydrates is linearly proportional to the temperature between 5° and 31°, and that a very rapid decrease in yield takes place when the temperature exceeds 31°. It was suggested that the explanation of this sudden decrease in activity was due to the fact that 31° marks the limit of stability of the adsorption complex of carbonic acid. This suggested explanation has now been verified experimentally. Suspension of the ferric oxide powders in water saturated with carbon dioxide are completely stable in the dark at 31° and at lower temperatures. If the temperature is raised above 31° the suspension is completely flocculated and rapidly settles out.

Measurements have been made of the photosynthetic efficiency of the powders with light of different wavelengths, and it has been found that the efficiency increases from the blue to the red end of the spectrum, the maximum being obtained with light of about wavelength 700 $\mu\mu$. The analogy between the laboratory process and that in the living plant seems therefore to be complete, since the two are similar in the following respects:

(1) The reaction is a photochemical one on a surface.

(2) The energy of activation of the carbonic acid is supplied in two stages, part by the surface and part in the form of light.

(3) The photosynthetic efficiency decreases when the intensity of the light is too great, and is restored in the dark.

(4) The production of photosynthesised material is linearly proportional to the temperature up to a critical temperature, above which the production rapidly falls. In the laboratory this critical temperature is 31° and in the living plant it is 36°.

(5) The photosynthetic efficiency increases from the blue to the red end of the spectrum.

It may be recorded that, although the yields of carbohydrates obtained from carbonic acid have not yet been large enough for the purpose, a systematic analysis has been made of the sugars present in the syrup photosynthesised from an aqueous solution of formaldehyde. This syrup is very similar in its properties to that obtained from carbonic acid. The sugars were oxidised by means of bromine and the resulting acids were separated by fractional crystallisation of their salts with various alkaloids. There were thus obtained pure preparations of *d*-gluconic acid and *d*-erythronic acid, both of which were completely identified. The formation of these acids proves the photosynthesis of glucose and fructose. Evidence was also obtained of the formation of dibasic acids, suggesting the photosynthesis of carbohydrates with larger molecular weights than the hexoses.

Agricultural Field Experiments.*

A FOREWORD explains that the pamphlet referred to below is published primarily for the benefit of officers engaged in field experimentation in the Madras Presidency. It is divided into three parts; the first introductory, dealing with the general principles underlying the work and with experimental technique; the second with various methods of grouping plots so as to minimise the disturbing influence of soil heterogeneity; and the third with the statistical concepts which are utilised in the analysis and interpretation of results. There is a short bibliography and a separate booklet of mathematical tables.

The authors rightly stress the necessity for selecting a uniform piece of land for experimental purposes, and for ensuring that the plant shall be uniform also. Recent advances in field experimental technique, although they may reduce the effects of non-uniformity, do not lessen the desirability of choosing the best possible site for an experiment. A debatable point is raised when it is stated (p. 3) that "no experiment can provide accurate data that is not based on a simple enquiry". Care should certainly be taken to ensure that the questions asked are straightforward and that the answers are therefore unambiguous; but much information can be gained from a complex experiment which is sought in vain in a simple experiment. Thus two simple experiments, investigating the effect of varying quantities of nitrogen in one case and of phosphate in the other, will not give information, obtainable if the two experiments had been combined, as to the effect of nitrogen at different levels of phosphate and of phosphate at different levels of nitrogen. Where more than two factors are introduced into a single experiment it becomes possible, of course, to calculate interactions of higher order than the first. In this connexion R. A. Fisher has written: "No aphorism is more frequently repeated in connection with field trials, than that we must ask Nature few questions, or, ideally, one question at a time. The writer is convinced that this view is wholly mistaken. Nature, he suggests, will best respond to a logical and carefully thought out questionnaire" ("The Arrangement of Field Experiments": *Jour. of Min. of Agric.*, 1925).

In the second part Beaven's half drill strip method is described, but without pointing out its two serious but remediable defects: that the continued use of one half of the drill for one variety, and of the other half for the variety with which it is to be compared, may introduce a constant difference the magnitude of which cannot be estimated; and that the regular alternation of strips of the two varieties does not permit of a valid estimate of experimental error. In this part the method of randomised blocks receives but scanty attention, and the Latin square method, which is by far the most efficient of all experimental arrangements, is not mentioned.

The third part indicates the procedure for calculating the standard deviation of the mean of a set of observations, and explains "Student's" method. A pamphlet published as recently as 1928 should have included an account of Fisher's "Analysis of Variance", that invaluable weapon of the field experimenter.

* "The Conduct of Field Experiments", by R. O. Iliffe and B. Viswa Nath. Bulletin No. 89 of the Department of Agriculture. (Madras: Government Press, Madras, 1928.) 1 rupee 4 annas.

Cyclones of the South Indian Ocean.

MR. R. A. WATSON, when director of the Royal Alfred Observatory, Mauritius, began a series of annual papers dealing with each cyclone season in that part of the South Indian Ocean lying near and to the east of Mauritius. They are published in the *Miscellaneous Publications* of the Royal Alfred Observatory. The second of the series, entitled "The Cyclone Season 1928–1929", shows that the season in question was a normal one in regard to the number of cyclones (8) that were noted. None of these storms caused damage in Mauritius, but Rodrigues suffered severely in January 1929.

The paper contains, in addition to the particulars of this one season, statistical information about the seasonal distribution and the movements of cyclones between the equator, lat. 30° S. and long. 50° and 70° E., based on 77 years' records beginning in 1848 that are not available elsewhere. This information extends and brings more up to date a part of the statistics that appeared in "Hurricanes and Tropical Revolving Storms", by Mrs. E. V. Newnham (*Geophysical Memoir*, No. 19), issued by the Meteorological Office, London, eight years ago. The manuscript records of the Observatory were used in addition to published information. Speaking of the seasonal variation in the number of cyclones recorded on each date, the author says: "The yearly variation is best represented by a slow rise throughout October and November, then a somewhat rapid rise to a maximum about Feb. 4, and a gradual fall to the end of May".

It may be noted that before the publication of the memoir referred to above, the best authority for the seasonal variation in the frequency of storms in the whole of the South Indian Ocean was Meldrum, who found from a consideration of 35 years' observations, also beginning in 1848, that more storms occurred in January than in February—71 as against 61 which implied an earlier date for the maximum than is now indicated. Mrs. Newnham's figures for the wider area accord well, however, with those found by Watson.

Watson also gives statistics in regard to the frequency with which all cyclones that crossed latitudes 10°, 15°, 20°, 25°, and 30° S. moved in the various directions: north, north-north-east, north-east, and so on. His remarks upon these have an important bearing upon the general question of the motion of tropical cyclones. He says, "The table is strongly suggestive of wind diagrams for various heights above the surface at Mauritius, the low latitudes corresponding to small heights and the higher latitudes to heights of 4 or 5 kilometres. . . . Given that the surface of separation between the easterly trades and the westerly 'anti-trades' slopes upwards from the surface about latitude 30° S. to reach very big heights about latitude 10° S., and that a cyclone is carried along by the prevailing current where condensation is taking place most vigorously, we should expect some such similarity." Before, however, this explanation can be accepted, it appears desirable to have direct evidence that the principal rain clouds show the very large variation in height in different latitudes that is implied. The suggestion opens up an interesting line of possible research.

University and Educational Intelligence.

CAMBRIDGE.—The professor of chemistry has, with the consent of the Vice-Chancellor, appointed S. E. Janson, of Gonville and Caius College, to be his assistant for five years as from July 1 last.

The Busk Studentship in aeronautics, founded in memory of E. T. Busk, who lost his life in 1914 whilst flying an experimental aeroplane, has been awarded for the year 1930–31 to R. H. Francis, of the University College of North Wales, Bangor.

N. F. Mott has been elected to an official corporate fellowship at Gonville and Caius College on his appointment as lecturer in mathematics. Mr. Mott was formerly a scholar of St. John's College, gained a first class in the Mathematical Tripos, Pt. I., and was a wrangler with distinction in Pt. II. in 1926. After working in Copenhagen, he was appointed lecturer in theoretical physics in the University of Manchester.

LONDON.—Notice is given that the Rogers prize for 1931, value £100, is offered for an essay on "Filtrable Viruses as a cause of Disease in Man". The competition is open to all persons whose names appear on the Medical Register of the United Kingdom. Copies of the regulations, including information regarding the date in April by which essays must be received, may be obtained on application to the Academic Registrar, University of London, South Kensington, S.W.7.

A SCHOLARSHIP has been founded at University College, Southampton, by friends of the late Dr. Alex Hill, in recognition of the distinguished services rendered by him to the College. The scholarship is of the value of £50 per annum, tenable for three years at the College, and will be awarded annually. The holder will be required to pay tuition fees. Dr. Alex Hill, who died on Feb. 27, 1929, became principal of University College, Southampton, in 1913, and steered the College through the difficult War and post-War years, until he resigned in 1920 to devote his energies to the rapidly developing work of the Universities Bureau of the British Empire. From 1920 until his death he was a vice-president of the College, so that he was actively connected with it for a continuous period of sixteen years.

THE following scholarships have been awarded by the Institution of Electrical Engineers for 1930:– *Ferranti Scholarship* (annual value £250, tenable for two years): E. Wilkinson (University of Liverpool); *Duddell Scholarship* (annual value £150, tenable for three years): T. R. Stretton (Cardiff Technical College); *David Hughes Scholarship* (value £100, tenable for one year): H. A. Wainwright (University of Sheffield); *Salomons Scholarship* (value £100, tenable for one year): E. Bell (Armstrong College, Newcastle-on-Tyne); *War Thanksgiving Education and Research Fund* (No. 1): grants of £50 each to F. J. Clark (East London College) and Miss W. Hackett (University of Birmingham); *Thorrowgood Scholarship* (annual value £25, tenable for two years): J. F. H. Tyler (Southern Railway Company).

THE Mond Nickel Company, Ltd., Imperial Chemical House, London, S.W.1, has arranged three exhibits showing aspects of the nickel industry, which are available, free of charge, to colleges, technical institutions, schools, etc., in connexion with conversaziones or to illustrate class or open lectures. Exhibit No. 1, illustrating "The Versatility of Nickel", was available last year. Exhibit No. 2 illustrates "The Extraction of Nickel by the Mond Process", and consists of flow sheet, photographs, samples of intermediate and fine products, letterpress, and booklets. Exhibit No. 3 illustrates "The Properties and Applications of Nickel and its Alloys", and consists of samples of products made in many different alloys, photographs, letterpress, and booklets. Lectures illustrated by travelling exhibits or lantern slides are also given by members of the firm's staff.

Historic Natural Events.

Oct. 26, 1916. Whirlwind in Essex.—A tornado travelled in a north-easterly direction across Essex near Writtle, passing through the centre of that village at 1.7 P.M. The track was only about 100 feet in breadth, and very sharply defined. Damage estimated at several thousand pounds was done to buildings in Writtle, but no lives were lost. An aneroid barometer was observed to fall an inch during the storm, and to recover in eight or ten minutes.

Oct. 27, 1913. South Wales Tornado. This disturbance was first observed in Devonshire shortly after 4 P.M., as a small but intensely black cloud from which fell torrential rain and hail of great quantity and size. It was accompanied by thunder and lightning, but the wind was not especially high. Travelling northwards, the storm crossed the Bristol Channel and appeared as a heavy thunderstorm at Aberthaw, but no material damage was recorded until it had penetrated 12 miles inland. From here onwards a great deal of damage was done along a sharply bounded track several hundred feet in width. Its passage lasted less than a minute, after which torrential rain fell. Trees were uprooted and buildings demolished; several pieces of slate were afterwards found buried to a depth of $1\frac{1}{2}$ inches across the grain of trees. After leaving Wales, the storm passed through Shropshire and Cheshire, reaching the latter at 8.30 P.M. The storm was noteworthy as the nearest approach to the true American tornado which has been scientifically investigated in England, its rotary motion being shown by trees lying in every direction, while others had their tops twisted off.

Oct. 28, 1891. Earthquake in Central Japan.—One of Japan's greatest earthquakes desolated the Mino-Owari plain near the centre of the Main Island. Over an area of 4286 square miles, the destruction of property was nearly complete, 197,530 buildings being ruined, while 7279 persons were killed. The earthquake was due to a sudden movement along a great fault, the scarp of which was traced across plain and mountain for 40 miles, and was believed to be nearly 70 miles in length. At the surface, the horizontal shift varied from 3 to 13 feet. The vertical displacement was usually less than 10 feet, but in one place reached nearly 20 feet. The after-shocks of this earthquake were unusually frequent. At Gifu, close to the fault-scarp, 1746 shocks were registered during the first thirty days and 3365 by the end of 1893.

Oct. 28, 1927. Breakdown of Electrical Transmission through Salt Spray.—On Oct. 28–29 a deep barometric depression crossed the British Isles, giving rise to a violent gale from south veering to west. At Southport the wind velocity reached 96 miles per hour in a gust and much damage was done. A remarkable feature of the gale was that in the Midlands electrical transmission along overhead power wires broke down from midday on Oct. 29 to early on Oct. 30. The cause of the trouble was afterwards found to be as follows: During the gale great quantities of spray were carried inland by the wind all along the west coast, and coated the insulators of the power lines in South Wales with a layer of salt water which practically short-circuited them. As the spray was carried inland, the water was evaporated owing to the dryness of the air, and by the time the air reached the Midlands the spray was reduced to salt crystals. These stuck on the insulators of the power lines but were too dry to destroy the insulation completely, until the air became damp again on Oct. 29, and they absorbed water. On Oct. 30 general rain washed the insulators clean again.

Oct. 29, 1867. The Hurricane of San Narciso.—This was one of the worst hurricanes on record in the West Indies. The storm passed across the Virgin Islands travelling towards the west-north-west, the centre reaching St. Thomas at 12.30 P.M., when the hurricane winds gave place to almost complete calm and darkness. More than six hundred persons were drowned at St. Thomas, mainly crews and passengers of vessels. On shore in St. Thomas and Tortola many deaths were caused by the falling of houses, which were almost all destroyed. Some houses were lifted bodily from their foundations and dropped some distance away. At Santa Cruz an American frigate was carried into the market place. This hurricane and the earthquake which accompanied it put an end to the almost completed negotiations for the purchase of the Danish West Indies by the United States. Continuing towards the west-north-west, the centre travelled diagonally across Porto Rico, where its effects were described in a work entitled "La Memorable Noche de San Narciso", by Don Vicente Fontan y Mera. In the various towns of the island 211 persons were killed, 741 injured, and an enormous amount of damage was done to houses and sugar mills. Owing to the torrential rains, there was much flooding.

Oct. 31, 1840. Rhone Floods.—On Oct. 27–30, from the Mediterranean to the Vosges, a general downpour of rain occurred, of unprecedented persistence and intensity. The Upper Rhone ravaged Lyons on Oct. 31; on Nov. 1 the Sâone surpassed all previous levels and all the torrents of the Cevennes were in violent flood. The Rhone had already risen more than 18 feet at Valence and more than 23 feet at Avignon, when a further terrific rainstorm burst over the valley from the evening of Nov. 1 to that of Nov. 3. In seven days, Oct. 27–Nov. 3, 9–10 in. of rain fell in the Rhone basin. The renewed floods fell like an avalanche on the already submerged valley; the Sâone rose 28 feet at Trévoux, inundated the lower parts of Lyons, and destroyed four bridges and several hundred houses. The Rhone at Avignon rose 27 feet above its normal level, and only the rupture of the dykes and consequent spread of the floods over an enormous tract of land prevented it from rising still higher. Near Tarascon the flood was nearly 20 miles across, and many bridges were washed away.

Nov. 1, 1755. Great Lisbon Earthquake.—This was one of the greatest of all recorded earthquakes. Coming without warning, the shock lasted six or more minutes, during which time about 60,000 persons were killed. The city of Lisbon was utterly ruined. Large numbers of persons had collected on a newly built stone pier, which sank suddenly with all upon it beneath the water. The epicentre lay about 100 miles west of Lisbon. The sea waves were of great height, about 50 ft. at Lisbon, 60 ft. at Cadiz, 15 ft. at Funchal, and 6–10 ft. along the southern coasts of England and Ireland. They swept across the Atlantic to the shores of Antigua, Barbados, and Martinique. An almost unique feature of this earthquake was the disturbance of lakes and rivers all over Europe and even in North America. In Loch Lomond (1220 miles from the epicentre), the water oscillated for $1\frac{1}{2}$ hours, at first to a height of 2 ft. 4 in. above the normal level. The Elbe at Hamburg (1400 miles), Lake Wener in Sweden (1750 miles), and the great lakes of Canada (nearly 4000 miles) were agitated.

Nov. 1, 1876. Backergunge Cyclone.—An intense cyclone travelled northward across the Bay of Bengal towards the delta of the Ganges, and a cyclone wave, ten to forty feet deep, struck the low-lying district of Backergunge in Bengal. In half an hour about 100,000 persons were drowned and all the crops were destroyed, and the disaster was followed by a famine and pestilence which cost a further 100,000 lives.

Societies and Academies.

PARIS.

Academy of Sciences, Sept. 15.—**Paul Helbronner**: The observation of a polar aurora. Observed Sept. 3, between parallels 65° 10′ and 64° 40′, on the occasion of the meeting of the International Congress of Geodesy and Geophysics at Stockholm.—**V. Romanovsky**: The discrete chains of Markoff.—**J. Rey Pastor**: A method of convergence by means.—**L. Bert** and **M. Raynaud**: A synthesis of propenyl benzene. The reaction between ω-chlorallyl benzene and sodium gave unexpected results, propenyl benzene, $C_6H_5.CH:CH.CH_3$, being the main product. The yield is sufficient to make this a good method of preparation of this hydrocarbon.—**Jean Piveteau**: The structural peculiarities of a new type of fossil fish from the Permo-Triassic formations of the north of Madagascar. This fossil has been previously described by Priem, and considered by him as belonging to the genus *Pristisomus*; the author does not agree with this view, and suggests the name of *Australosomus* as the name of a new genus.—**J. Vellard** and **Jarbas Penteado**: The action of ultra-violet rays on venoms. Experiments were made on venoms from *Lachesis atrox*, *L. jararaca*, *Crotalus terrificus*, *Naja tripudians*, and *Bufo marinus*. An account of the changes in physical and chemical properties is given. The physiological action was found to be considerably reduced by exposure to ultra-violet light. With large doses of venoms irradiated for 45 minutes, the authors have been able to protect guinea-pigs and goats against the action of a subsequent injection of fatal doses of fresh venom.

CAPE TOWN.

Royal Society of South Africa, Aug. 20.—**T. Stewart**: Steenbras rainfall. The yield of the catchment area for the wet months might be put at 6000 million gallons. This is the capacity of the reservoir which has recently been constructed. In 1922 observations for a period of seven years were available. These showed that the average amount of rainfall in the main valley for the period was 40·7 inches. The observations taken since, that is, over a period of fourteen years, give 39·3 inches for the main valley. This does not apply to the whole catchment.—**K. H. Barnard**: The Cape alder-flies (Megaloptera). Third report on the fauna of the mountains of the Cape Province. Five species are admitted, comprised in four genera. The egg, larva, and pupa of one species, and the larva and pupa of another, have been discovered.—**H. Zwarenstein**: A note on Bridge's genic balance theory of sex determination. The following modification is suggested: the female determining genes are located not only on chromosome X but also on chromosome IV. The male determining genes are in chromosomes II and III. Assigning arbitrary values to the efficiency of these two interacting components, a series of sex indices is derived.—**L. T. Hogben**: Spinal transection and the chromatic functions in *Xenopus Laevis*. Section of the optic nerves has the same effect as removal of the eyes. Section of the entire peripheral nerve supply of the leg has no effect on colour response. Both the black and white background response can be elicited in toads after section of the cord in front of the first pair of spinal nerves or at any lower level.—**Enid Hogben**: The total oxygen consumption of hypophysectomised toads. The ratio of dermal (Winkler method) to pulmonary (Haldane method) respiration has been determined, and the variation of total respiratory rate with temperature, body weight, and sex has been determined. Removal of the pituitary gland is accompanied by a profound diminution in the oxygen consumption.—**J. Hewitt**: Discoveries in a bushman cave at Tafelberg Hall.

LENINGRAD.

Academy of Sciences (*Comptes rendus*, No. 3, 1930).—**V. Ambarzumian** and **D. Ivanenko**: A note on the problem of the unified theory of the electromagnetic and the gravitational field from the point of view of the quantum mechanics.—**A. Mordvilko**: *Pemphigus bursarius* Tullgren (*pyriformis* Licht.) and its anolocyclic forms. The alate forms of *P. bursarius* migrate from the galls on poplars to roots of grasses, where they give rise to exules which have been described under different names. Galls of *P. bursarius* do not occur on poplars (*P. suaveolens* and *P. maximowiczii*) in eastern Siberia, though the root-forms are present; it is possible that *P. nigra* existed there in the preglacial times.—**D. Smirnov**: Systematics of *Diaptomus fischeri* Rylov and *Diaptomus acutulus* Brian. The two species are extremely close, but differ by a number of characters, which are enumerated and analysed.—**J. Medvedev**: The relation of a diastase to the substratum in a system of carboxylase and pyruvic acid.

Comptes rendus, No. 4, 1930.—**V. Ipatjev** and **A. Frost**: Chemical equilibrium between phosphine, phosphorus, and hydrogen.—**J. Kourbatov, N. Karzhavina,** and **N. Samoilo**: Description of a method for the preparation of a solution serving for the determination of ionium in the dispersed masses of Tuia-Mouiun.—**S. Smirnov**: (1) A new species of *Phyllopoda anostraca* from the Ussuri region. Description of *Pristicephalus longicornis* sp. n.—(2) A new species of the genus *Diaptomus* Westw. from the Amur region. A description of *D. ryloci* sp. n., closely allied to some North American species of the genus.—**V. Gromova**: Preliminary communication on the *Bos primigenius* Boj. in Russia. A series of thirteen skulls of *B. primigenius* was studied and great individual variability established; this throws some doubt on the validity of a number of species described by other authors, and only two of these may be retained, namely, *Bos trochoceros* Meyer of the glacial period and the postglacial *B. primigenius* Boj.—**G. Alderberg**: Preliminary synopsis of Russian and Mongolian wild boars. Only one species of *Sus* is recognised, with five subspecies, namely, *S. scrofa scrofa* L. (Germany), *S. s. attila* Thomas (Transylvania, Russia, Caucasus), *S. s. nigripes* Blanford (Turkestan, Tian-Shan), *S. s. raddeanus* sbsp. n. (N. Mongolia), and *S. s. continentalis* Nehring (Amur and Ussuri basins).

SYDNEY.

Royal Society of New South Wales, Aug. 6.—**A. R. Penfold, C. B. Radcliffe,** and **F. W. Short**: The essential oil of *Eucalyptus rariflora* (Bailey). The air-dried leaves yielded 2·5 per cent of oil, the principal constituents of which have so far been identified are the terpenes Δ-4 carene, *B.* phellandrene, *l*-a-pinene, *B.* pinene, cymene with cineol (about 10 per cent), sesquiterpenes (principally aromadendrene), sesquiterpene alcohols, with small quantities of the aromatic aldehydes (cuminal, phellandral, and cryptal), alkali soluble bodies (unidentified phenols) and dehydroangustione (*B.* diketone).

VIENNA.

Academy of Sciences, June 26.—**E. Beutel** and **A. Kutzelnigg**: The catalytic action of light on the disintegration of certain salts.—**W. J. Müller**: The theory

f passivity phenomena (12). The passage of a curent through anodes which are covered with an insolble surface layer. A formula is suggested based on ssumptions as to the division of the current between he surface-layer and its pores.—**J. Zellner** and **E. Zikmunda**: The chemistry of halophytes.—**J. Zellner** and **E. Zikmunda**: The chemistry of higher fungi (21). *Polyorus sulfureus* and *Lentinus squamosus*.—**N. Froschl, . Zellner** and **E. Zikmunda**: The comparative chemstry of plants, chemistry of barks (7). *Morus nigra* and *Alnus incana*.—**E. Gebauer-Fülnegg** and **H. Jarsch**: Condensation products from aryl-dithio-glycolic acids. —**E. Riess**: Organic sulphur-nitrogen linkage.—**H. Huber** and **K. Brunner**: The action of ferric chloride on the acyl esters of phenol.—**F. Perktold**: Para-azobenzol-sulphonic acid and paramononitro-para-azobenzol-sulphonic acid. **F. Raaz**: The space-unit of gehlenite. Pure synthetic material was prepared in he Kaiser Wilhelm Institute for silicate research at Berlin-Dahlem and submitted to X-ray analysis in Leipzig. The elementary unit is a tetragonal prism with two molecules of the compound $Ca_2Al_2SiO_7$.—**. Kisser** and **A. Sesser**: Biological researches on dwarf trees (1). The structural relations of the high moor forms of *Picea excelsa*. Trees fifty years old were only 60 cm. high and 2 cm. in diameter. The leaves show a diminution in the number of cells rather than in the size of cells.—**W. Laves**: Histological researches with buffered stain solutions on the post-mortem breakdown of the nuclear chromatin and of the plasma of liver cells.—**O. Taussky**: The metrics of groups. **E. Bersa**: Culture and nutrient physiology of the genus *Pilobolus*. The favourable and unfavourable nitrogen and carbon sources were determined. **A. Himmelbauer**: The crystalline form of cadmium antimonide. Form rhombic, formula CdSb. **H. Gerhart**: Alterations of crystalline form in double sulphates. Crystals were obtained from solutions containing additions deliberately introduced. Magnesium, cadmium, and manganese double salts cause deformations of copper, nickel and zinc double salts.—**L. Goebel**: Radioactive disintegration phenomena in the fluorite of Wölsendorf. Haloes are formed and these have been examined with he ultramicroscope. An explanation of the colours of fluor spar is offered in terms of the size of colloid particles of calcium.—**R. Steinmaurer**: Observations on the variations of the Hessian cosmic ultra-radiation on the Hohen Sonnblick (3100 metres) in July 1929. Registering apparatus was used, both in half-open and in a completely enclosed 7 cm. thick iron-clad electroscope. The measurements were arranged according to sidereal time. There was also a small barometric effect, and other unexplained irregularities.—**T. Pintner**: Little known and unknown tapeworms.—**A. Zinke** and **R. Wenger**: Perylene and its derivatives (29). The decomposition of perylene to benzanthron. —**A. Zinke** and **O. Benndorf**: Perylene (30).—**A. Pongratz**: Perylene (31).—**F. Halla** and **E. Mehl**: The space-lattice of natrolite. The unit contains eight molecules of $Na_2Al_2Si_3O_{10}$, $2H_2O$.—**A. Brukl**: The hetero-poly acids of germanium. Molybdenum and tungsten unite with germanium to form acids.—**K. Vanek**: Division properties of curves connected in detail.—Communications of the Radium Research Institute.—(No. 258) **B. Karlik**: The scintillation faculty of calcium tungstate.—(No. 259) **M. Blau**: Quantitative research on the photographic action of α- and H-particles.—(No. 260) **F. Urbach**: The breadth of bands and the dependence of emission bands on temperature in alkalihalide phosphorescence.—(No. 261) **F. Urbach**: The luminescence of alkali halides. Preace and visual observations (1).—(No. 262) **F. Urbach**: Luminescence of alkali halides (2).—**R. Holzapfel**: Chief results of radiation measurements on the Stolzalp in the period November, 1928 to October, 1929.—**O. Beran**: Conductivities and counter voltages in ion-conducting crystals.—**M. Beier**: Zoological expedition to the Ionian Islands and the Peloponnesus (13). *Hymenoptera parasitica* by C. Ferrière.—**L. Waagen**: The geological structure of the highlands between Frohnleiten, Übelbach and Deutsch-Feistritz in Styria.

CATALOGUE.

Collections and Apparatus required for the Study of Geology. Pp. 24. (London: Thomas Murby and Co.)

Diary of Societies.

FRIDAY, OCTOBER 24.

ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botany Lecture Room, Imperial College of Science and Technology), at 2.30.—M. A. H. Tincker: Growth Studies on Oats.—M. Jones: The Yielding Capacity of Oat Varieties under Different Conditions of Soils and Climate.—Dr. P. S. Hudson: The Differentiation of the Wheat Ear.

ROYAL SOCIETY OF MEDICINE (Disease in Children Section), at 5.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Newcastle-upon-Tyne), at 6.—J. McGovern: Presidential Address.

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (jointly with Institute of Chemistry) (at Liverpool University), at 6.—Dr. P. Lewis-Dale: Chemistry in the Service of the Railway.

SOCIETY OF DYERS AND COLOURISTS (London Section) (at Dyers' Hall, Dowgate Hill), at 6.45.—Dr. E. F. Armstrong: The Future of the Dyestuff Industry: have we Fought in Vain?

INSTITUTION OF LOCOMOTIVE ENGINEERS (Manchester Centre) (at Manchester Literary and Philosophical Society, Manchester), at 7.—H. K. Bamber: The Effect of Road upon Rail Transport and its Influence on Locomotive Design (Presidential Address).

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—J. L. Hodgson and others: Discussion on What are the Desirable Objectives of the Age of Power?

MANCHESTER ASSOCIATION OF ENGINEERS (at Engineers' Club, Manchester), at 7.15.—J. Frith and F. Buckingham: Stored Energy.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—A. P. Morris: Bitumen Emulsions, with Particular Reference to their Use on Indian Roads.

LEICESTER TEXTILE SOCIETY (at Victoria Hall, Leicester), at 7.30.—E. Lomas: Pure Silk Manufacture.

ROYAL SOCIETY OF MEDICINE (Epidemiology Section), at 8.—Dr. Major Greenwood: Public Health Education (Presidential Address).

INSTITUTION OF CHEMICAL ENGINEERS (Graduates' and Students' Section).—J. E. Duckham: Lubrication as applied to Chemical Engineering.

SATURDAY, OCTOBER 25.

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (at Newcastle-upon-Tyne), at 2.30.—A. L. Ford: Machine Mining in Faulted Ground.—Dr. W. Hopkins: A Record of the Upper Carboniferous Non-Marine Lamellibranchs of Northumberland and Durham, and a Record of their Sequence. Papers open for further discussion:—The Pitman's Yearly Bond, by Prof. H. Louis; The Surveying of Bore-holes, by J. T. Whetton.

BRITISH PSYCHOLOGICAL SOCIETY (at Bedford College for Women), at 3.30.—Miss Madeline Kerr: Unseen Drama and Imagery, Experimental Observations.—Prof. T. H. Pear: Psychological Problems suggested by Radio-Drama.

MONDAY, OCTOBER 27.

CAMBRIDGE PHILOSOPHICAL SOCIETY (Annual General Meeting) (in Cavendish Laboratory), at 4.30.—H. C. Webster: The Capture of Electrons by α-particles.—Dr. N. A. de Bruyne and H. C. Webster: Note on the Use of the Thyratron with a Geiger Counter.—N. Feather: An Unsuccessful Attempt to Influence the Normal Decay of a Weak Source of Polonium.—Dr. F. L. Arnot: Note on the Angular Scattering of Electrons in Gases.—H. S. W. Massey: The Theory of the Scattering of X-rays by Molecular Hydrogen.—*Papers to be communicated by title only*:—Dr. G. Temple: The Matrix Mechanics of the Spinning Electron.—S. Verblunsky: (*a*) A Property of Continuous Arcs II; (*b*) Note on the Sum of an Oscillating Series II.—W. G. Welchman: The Number of Contact Primes of the Canonical Curve of Genus *p*.—R. Hargreaves: Wave Forms and a Special Problem.—Prof. L. J. Mordell: Note on Some Linear Diophantine Inequalities.—R. E. A. C. Paley and A. Zygmund: On some Series of Functions (2).—R. E. A. C. Paley: On the Strong Summability of Fourier Series.—H. R. Hasse: The Polarisability of the Helium Atom and the Lithium Ion.

ROYAL SOCIETY OF EDINBURGH, at 4.30.—Annual Meeting.

INSTITUTE OF ACTUARIES, at 5.—H. M. Trouncer: Presidential Address.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—C. C. Paterson and others: Discussion on The Link between Sales, Manufacture, and Research.

SOCIETY OF CHEMICAL INDUSTRY (Yorkshire Section) (jointly with Fuel Section) (at Hotel Metropole, Leeds), at 7.—Dr. W. H. Blackburn and Prof. J. W. Cobb: The Influence of Furnace Atmosphere upon the Scaling of Steel.—Dr. A. Key and Prof. J. W. Cobb: The Determination of the Reactivity of a Coke to Steam and CO_2.

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8.—C. Schelling: The Odontological Society in the Last Decade of the 19th Century.

BRITISH PSYCHOLOGICAL SOCIETY (Industrial Section) (at National Institute of Industrial Psychology), at 8.15.—Dr. W. J. Pinard: Perseveration as a Means of Testing Leadership.

TUESDAY, OCTOBER 28.

ROYAL SOCIETY OF MEDICINE (Medicine Section), at 5.—Dr. J. A. Ryle, Prof. H. Moore, Dr. Helen Mackay, and others: Discussion on Research in Clinical Medicine.

INSTITUTE OF METALS (Swansea Local Section) (at Thomas's Café, Swansea), at 6.15.—Dr. W. Rosenhain: Impurities in Copper.

INSTITUTION OF ELECTRICAL ENGINEERS (East Midland Sub-Centre) (at Technical College, Derby), at 6.30.—H. H. Dyer: Some Applications of Electricity to Railway Signalling.

INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—H. G. Fraser: Chairman's Address.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—Sir William Bragg: X-rays and the New Range of Vision (Hurter and Driffield Memorial Lecture).

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Centre) (at King's Head Hotel, Coventry), at 7.30.—Sir Herbert Austin: The Future Trend of Automobile Design (Presidential Address).

INSTITUTION OF ELECTRICAL ENGINEERS (North-Western Centre) (at Midland Hotel, Manchester), at 7.30.—A. L. Lunn: Chairman's Address.

INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Centre) (at 39 Elmbank Crescent, Glasgow), at 7.30.—E. Seddon: Chairman's Address.

SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield), at 7.30.—Dr. W. H. Hatfield: Nitride Hardening.

WEDNESDAY, OCTOBER 29.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (at Bolbec Hall, Newcastle-upon-Tyne), at 7.15.—M. Waters: Chairman's Address.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Tees-side Branch, Graduate Section) (at Middlesbrough), at 7.30.—T. P. Richards: Chairman's Address.

THURSDAY, OCTOBER 30.

INSTITUTION OF AUTOMOBILE ENGINEERS (Manchester Centre) (at Engineers' Club, Manchester), at 7.—Sir Herbert Austin: The Future Trend of Automobile Design (Presidential Address).

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Tees-side Branch) (at Middlesbrough), at 7.30.—Addresses by J. McGovern and J. R. Dippie.

INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre—Dublin) (at Trinity College, Dublin), at 7.45.—F. H. Whysall: Chairman's Address.

CHEMICAL SOCIETY, at 8.—N. I. Fisher and F. M. Hamer: A General Method for the Preparation of Thiocyanine Dyes. Some Simple Thiocarbocyanines.—Dr. W. H. Mills and I. G. Nixon: Stereochemical Influences on Aromatic Substitution. Substitution Derivatives of 5-hydroxyhydrindene.—Prof. C. S. Gibson and J. D. A. Johnson: Syntheses with ββ'-dichlorodiethylether. Part II. Heterocyclic Compounds containing Two Different Atoms of the Oxygen Group in the Ring. 1:4-selenoxan.

FRIDAY, OCTOBER 31.

INSTITUTION OF ELECTRICAL ENGINEERS (West Wales (Swansea) Sub-Centre) (at Corporation Electricity Showrooms, Swansea), at 6.—Sir A. Whitten Brown: Chairman's Address.

INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section) at 6.15.—H. T. Young: Is the Engineer of To-day making the Best Use of his Opportunities in Electrical Development in this Country?

INSTITUTION OF CHEMICAL ENGINEERS (at Institution of Civil Engineers), at 6.30.—Prof. W. A. Bone: High-Pressure Reactions (Lecture).

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7.30.—L. T. Westbury: The Two-stroke Engine.

GEOLOGISTS' ASSOCIATION (in Great Hall, University College), at 7.30.—Annual Conversazione.

IMPERIAL COLLEGE CHEMICAL SOCIETY (in Main Chemistry Lecture Theatre, Royal College of Science).—Prof. J. F. Thorpe: The Life and Work of W. H. Perkin, Jun.

SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section) (at Glasgow).—Dr. S. Miall and others: Discussion on the Journal of the Society.

MEDICAL SOCIETY OF LONDON.—Sir Almroth Wright and others: Discussion on The Prophylactic and Therapeutic Values of Vaccines.

PUBLIC LECTURES.

FRIDAY, OCTOBER 24.

UNIVERSITY COLLEGE, LONDON, at 5.30.—Prof. A. Penck: The Relations of Europe and Central Asia. (Succeeding Lecture on Oct. 27.)

SATURDAY, OCTOBER 25.

UNIVERSITY OF BRISTOL (in Henry Herbert Wills Physical Laboratory), at 11.15 A.M.—Prof. J. Franck: Relations between Spectroscopy and Chemistry (Henry Herbert Wills Memorial Lecture).

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Dr. C. Ainsworth Mitchell: Stories told by Hairs and Fibres.

MONDAY, OCTOBER 27.

UNIVERSITY OF EDINBURGH (in Greek Class Room, Old Quadrangle, University, Edinburgh), at 8.—Capt. C. W. Hume: The Universities and Animal Welfare.

TUESDAY, OCTOBER 28.

KING'S COLLEGE, LONDON, at 11 A.M.—S. P. Turin: The Economic Geography of U.S.S.R.: Means of Communication and Transport.

WEDNESDAY, OCTOBER 29.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Lt.-Col. J. A. A. Pickard: The Prevention of Street Accidents.

UNIVERSITY OF LIVERPOOL (in Arts Theatre), at 8.—Prof. S. Brodetsky: Ancient Jewish Astronomy.

THURSDAY, OCTOBER 30.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—C. P. Blacker: Sterilisation of the Unfit.

UNIVERSITY OF DUBLIN, at 5.—Dr. F. S. Lavery: Trachoma, with Special Reference to its Sociological Aspect (Montgomery Lecture).

BRITISH MEDICAL ASSOCIATION (Hastings Hall, Tavistock Square), at 5.15.—Dr. G. Slot: Rheumatism in Childhood (Chadwick Lecture).

UNIVERSITY COLLEGE, LONDON, at 5.30.—Miss E. Jeffries Davis: Re-plannings of London, c. 1520–1920. (Succeeding Lectures on Nov. 6, 13, 20, and 27.)

SATURDAY, NOVEMBER 1.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—D. Martin Roberts: London in the Stuart Age.

CONGRESS.

NOVEMBER 1 AND 2.

INSTITUTE OF SOCIOLOGY (at Imperial Institute).—Lectures and Discussions on Sociological and Survey Topics.

SATURDAY, NOVEMBER 1, 1930.

CONTENTS.

Editorial and Publishing Offices:

Science and Broadcasting.

IT has been rather bitterly remarked that the most attractive feature of a wireless set is that there is no necessity to have one. Many people, indeed, hold that the violation of domestic privacy by the telephone, and more particularly by the wireless set, is a thing to be deplored; and this attitude is by no means confined to those unappreciative of the benefits science has lavished upon us. Dislike of broadcasting is frequently based upon the feeling that the public is far too prone to take its opinions and its entertainment ready-made—something to be bought and paid for as one would buy a box of cigarettes. There is good cause for this feeling. The popular Press, for example, is in many ways admirable; but it would be idle to deny that the enormous circulations of modern newspapers inevitably tend forcibly to mould and stereotype public opinion, while the very fact that they cater for the masses necessitates (or apparently necessitates) a comparatively low level of intellectual outlook. The mental indolence of much of the nation is accompanied by an emotional or æsthetic indolence in choice of amusement. Instead of amusing or entertaining themselves, many people prefer to pay to be amused, and generally select that form of amusement which involves the least effort on their own part. "I like to go to the cinema once a week," said Miss Pinnegar in "The Lost Girl". "It's instruction, you take it all in at a glance, all you need to know, and it lasts you for a week. You can get to know everything about people's actual lives from the cinema." Although cinema-goers are now much too sophisticated to imagine that the film bears any sort of relation to "people's actual lives", it yet remains true that "you take it all in at a glance", and if your amusement is solely of this soporific character, taste for intellectual pleasure cannot fail to atrophy.

Those who condemn broadcasting on such grounds as have been thus briefly indicated can surely have listened-in but seldom. Whatever may be said of certain foreign stations, the British Broadcasting Corporation has consistently and steadfastly striven at a much higher aim, and on the whole with a success that must have been as gratifying to its directors as beneficial to the nation at large. It cannot have been an easy matter to plan and to realise policies and programmes that have met with such widespread and well-merited approval, not merely from the general public but also from those best qualified to

pass a critical and considered judgment on moral, æsthetic, and cultural grounds. One of the chief difficulties lies in the varied types of listeners, many of whom are only too ready to find fault with any programme that does not coincide with their personal preferences. In a foreword to the list* of broadcast talks for September to December 1930, the Hon. Harold Nicolson describes, with his usual felicitous wit, the ideal qualities of a reasonable listener: he should be unselfish, modest, patient, and able to exercise judicious selection. "He may be a busy City magnate," says Mr. Nicolson, "and, as such, feel that his attitude towards 'Ways of Cooking Fish' is, to say the least, impersonal. But there are countless other people whose days are darkened by this problem, and for whom the voice of an instructor on the subject is the voice of a true friend." As to patience, Mr. Nicolson himself seems to have little of this virtue to exercise on the 'twiddler'—the man whose chief delight is to tune in one station after another simply for the satisfaction of having got them. While we can sympathise with Mr. Nicolson's irritation at "that impatient type of egoist", we confess to a weakness for wandering off to Langenberg, Milan, or preferably Toulouse (for the ever-flowing and inconceivably soothing voice of its announcer!) when the B.B.C. is prattling of League football results or 'Autumn ailments of the Wyandotte'.

Small grumbles often conceal a great satisfaction, and men of science must feel especially satisfied with the quality and quantity of scientific matter included in this autumn's programme. Sir James Jeans is giving six lectures on "The Stars in their Courses"; Lord Moynihan, Sir Humphry Rolleston, and others of equal eminence, are talking on the future of medicine; Dr. D. Jordan Lloyd is speaking on the possibilities of synthetic food-stuffs; and Mr. B. H. C. Matthews is dealing with the electricity in our bodies. These names and subjects by no means exhaust the scientific section of the programme, but they serve to indicate that the B.B.C. committee casts its net widely and well, and that the adult portion of our population may still, if it will, be initiated into some of the habits of scientific thought and become familiar with important aspects of scientific progress and discovery.

A study of the programme shows that the ground covered—and covered by authoritative exponents—is really very extensive, and we feel that all who are in a position to do so should make an effort to ensure that the listening public derives as much benefit as possible from the fare thus generously and intelligently spread before it. It would, for example, be attractive to arrange group discussions of such talks as those on Tuesdays at 7.25 ("A Study in Population" and "The Future of the Race") and 8 o'clock ("The Mind of a Child" and "The Stars in their Courses"); adult education societies, debating clubs, and young men and women's societies ought to welcome opportunities of this kind, particularly if someone trained in science, medicine, or psychology would take the chair and direct the discussion. Free interchange of thought and opinion upon subjects of immediate interest will always be welcomed by large numbers of people who, in the absence of such stimulus, would spend their evenings in less profitable and probably more lethargic ways. Those of us who have given semi-popular lectures on scientific topics to audiences in small provincial towns or villages will agree that the desire for knowledge, in the middle classes and better sort of working classes in particular, is refreshingly vigorous; one may, indeed, go so far as to call it pathetically vigorous, for at present it is far from likely to be adequately fulfilled. The B.B.C lectures, properly utilised, might do much to foster this love of knowledge and to train it upon the best lines. To bring about a widespread understanding of the nature of science, in a world that owes its continued existence to science but is nevertheless dangerously ignorant of that fact, would be an achievement full of the happiest prospects for the future of civilisation.

The possibilities of broadcast talks in connexion with school work ought also to receive more consideration than appears to be the case at present, though several educational associations have subcommittees to watch the matter. There are admittedly difficulties of time-table, and the school curriculum is already overcrowded, but it would surely be of great value to boys and girls if they could listen to such lectures as those on "Keeping Fit in Everyday Life". The cost of reliable receiving sets is now so small that expense can scarcely be regarded as a serious obstacle to the general use of wireless in schools; yet we think we are right in saying that a school which will cheerfully pay several guineas to a lecturer may often be found innocent of a loud speaker. The B.B.C. has shown itself so ready to comply with reasonable requests, and so enthusiastic for the cultural advancement of the nation, that we

* Broadcast Talks, September to December 1930. (London: British Broadcasting Corporation, Savoy Hill, W.C.2.) Gratis.

can be sure it would immediately respond to any approaches made to it by those responsible for the education of children. There would certainly be an immense stimulus to school science if, say once a week, one could tune in to a lecture on some scientific subject by an expert.

The present occasion is perhaps one on which a point of more general interest may be raised. Men of science, in spite of a popular but quite fallacious belief in the contrary, are keenly concerned over speech, language, and pronunciation, and view with alarm the growth of what one can only describe as a 'broadcast accent'. Uniformity of pronunciation over the whole country may or may not be desirable, and there may be technical difficulties in transmission; but we would respectfully inquire of the B.B.C. whether the familiar phrase 'forecast of to-day's weather' must necessarily be rendered 'fahcast of ta-dess wetha', and why the final *r* in 'tar' has been removed from its rightful place to form an unlovely appendage to 'law'. E. J. HOLMYARD.

Schiaparelli's Studies of Mars.

Le opere di G. V. Schiaparelli. Pubblicate per cura della Reale Specola di Brera. Tomo 1. Pp. x+515+19 tavole. 220 lire. Tomo 2. Pp. iv+486+30 tavole. 220 lire. (Milano: Ulrico Hoepli, 1930.)

WITH the appearance of these two stately volumes, we are witnessing the erection of yet another of those literary monuments which are raised from time to time by foreign countries to the memory of their great men of science. Tycho Brahe, Galileo, and Huygens have thus been commemorated during the last few years, while Kepler under discussion for a similar honour, and now Italy is once more adding to her laurels by undertaking the publication, in a superb edition, of the complete works of Giovanni Virginio Schiaparelli.

For some time past, a need had been felt for a eprint of certain of the works of Schiaparelli, more especially of those which by reason of their scarcity vere practically unobtainable by the student, so that when this matter was brought forward by Prof. rancesco Porro on the occasion of the fourteenth ongress of the Italian Society for the Advancement Science, held at Pavia in May 1925, it was unanimously decided to undertake the publication of he complete works of Italy's greatest astronomer in an edition which should have national importance nd should be modelled on the following lines:

(1) All Schiaparelli's works to be included.

(2) Writings dealing with one particular subject to be printed in immediate chronological sequence. Thus, the two first volumes now before us contain all that Schiaparelli has written about the planet Mars, while future ones will deal with his important work on the connexion between comets and meteors, his researches in ancient astronomy, and the many other scientific questions that engaged his attention.

(3) The new edition to be based on the author's own corrections and emendations, as existing in the copies of his works preserved at the Brera Observatory.

Schiaparelli's actual correspondence with scientific men, however, which was most voluminous and is now scattered throughout the pages of the world's scientific journals, will not be included in the proposed volumes, but may possibly follow later as a separate publication. That this is a wise decision on the part of the committee working on this new edition will be readily conceded when it is recalled that Schiaparelli's scientific labours are to be found in some 256 separate publications ranging over the whole domain of astronomy, both ancient and modern, not to speak of numerous papers trenching on the realms of literature and art, for he was a profound classical scholar whose versatility was without apparent limit.

Although our author's remarkable discovery so early as 1866 of the connexion between the orbits of comets and meteors—a discovery for which he was awarded the gold medal of the Royal Astronomical Society—as well as his noteworthy researches many years later on the rotation periods of Mercury and Venus, were fully equal to any of his other achievements in astronomy, introducing, as they did, wholly new and unexpected elements into our views concerning the heavenly bodies, it is unquestionably with his work on Mars that the world in general will always associate his name. Beginning his observations of the planet during the opposition of 1877, and continuing them until the opposition of 1897, Schiaparelli gave to the astronomical world the most complete description of the physical appearance of Mars that had ever been published, and it is these early studies in areography which have been chosen to form the contents of the two volumes recently issued.

Considering the great name Schiaparelli afterwards made for himself as an authority on Martian phenomena, it is interesting to read in the introduction to his first memoir on the planet's axis of rotation and topography (vol. 1, p. 11), presented to the Royal Academy of the Lincei in May 1878, that, in directing his attention to Mars during

the favourable opposition of 1877, it was by no means his intention to institute a course of regular observations of its surface, but rather to test the Merz 8½-inch refractor of the Brera Observatory, which had already proved itself so efficient in double star work, as to its suitability for planetary detail. The first results, he confesses, were anything but encouraging, for he had the misfortune to commence his observations during a difficult aspect of the planet, and it was some little time before he was able to recognise certain of the features which had been charted by Kaiser and Lockyer during the opposition of 1862. His ultimate success with these, however, as well as the general excellence of the images obtained, convinced him that, though of modest aperture, the Merz telescope was fully capable of doing good work on the planet, and, encouraged by fine weather, he decided to continue his observations, with the remarkable result which these volumes are now published to commemorate.

From the outset Schiaparelli had attacked the problem before him in a severely methodical manner, and, as this first memoir shows, the exhaustive discussion of the large number of micrometric measurements obtained enabled him to give an accurate determination of the Martian axis of rotation. This important result, coupled with the careful delineation—made on strictly geometrical principles—of the planet's physical features, formed the basis of the highly particularised maps which accompany his work, and of which he could truthfully claim (vol. 1, p. 12) that, in point of detail, they far excelled anything dealing with Martian phenomena published up to that time.

It was precisely the wealth of detail recorded, however, that moved Schiaparelli to the adoption of a brand-new nomenclature. At first he was inclined to use the topographical terminology invented by Proctor, though he soon abandoned the idea in favour of the names, now become doubly classic, taken from the geography of the ancients. Thorough classicist that he was, he tells us (vol. 1, p. 61) that as he stood working at the telescope he was reminded by the peculiar demarcation of the Martian topography of the celebrated 'diaphragm' of the Greek geographer and historian, Dicaearchus, whose Βίος τῆς Ἑλλάδος was familiar to him. The euphonious geographical terms used by the Greeks, he says, appeared at once to afford the best means of avoiding all danger of confusion with earlier Martian nomenclatures while offering an opportunity of describing fittingly the totally novel features he had observed on the planet. He modestly adds, however, that he has no desire to be taken too seriously in the matter and is willing to leave to posterity the choice of a more appropriate terminology.

The passages in these two volumes to which the reader will turn with pardonable curiosity will doubtless be those where Schiaparelli first introduces his famous canals and then describes their gemination. In the first volume he states his reasons for calling the streaks he saw *canali* (vol. 1 p. 167 *et seq.*), a word which properly signifies *channels*, but has been translated into both English and French as *canals*, thus connoting a certain degree of artificiality. He mentions the furrows and 'rills' familiar to lunar observers and then speaks of the channels of the Martian landscape, maintaining that as there are "solchi della Luna", so also may there be "canali di Marte". As regards the *gemination* of the latter, perhaps the most graphic general account of this much-debated phenomenon will be found in the long Germ n article originally contributed to *Himmel und Er* n 1889, and now reprinted as an introduction t the second volume (vol. 2, pp. 3-46). Our author repeats at somewhat greater length the vivi scription concerning the duplication of the which he had presented to the Royal Aca of the Lincei during the opposition of 1881–82, when, in anticipation of the general scept which he knew his statements must call he had hastened to add the declaration (v p. 386) that the observed duplicity could in no w be due to eye-strain, or any form of strabism causing diplopia monophthalmica, considering tha every precaution against ocular fatigue on his part had been duly observed.

Schiaparelli had already given such frequent proof of his careful, accurate, and conscientious work as an observer that these totally unexpected results of his were received with astonishment and incredulity. Though held to be based in some unexplained way upon actual changes, seasonal or other, taking place on the planet's surface, th appearances themselves were thought to belon to psychological optics rather than to astronomy, and a vague analogy was sought in the well known difficulties experienced by the microscopist when working with high powers on the resolution of diatomaceous frustules. Schiaparelli himself had carefully refrained from offering any sort of explanation of the singular phenomena observed. To do so, he said (vol. 1, p. 506), would be rash beyond compare—" sarebbe una temerità senza pari ! "

Whatever verdict posterity may find with regard to the interpretation placed upon these results,

there can be no doubt whatever as to the lasting value of Schiaparelli's work. In many ways he was the ideal observer, who studies not only the object observed, but also the exact circumstances, physiological as well as physical, attending the observation. He described his instruments with obvious pride, and, while not a little envious of the larger apertures possessed by other nations, he was well content to do his utmost with a smaller but first-class telescope aided by the limpid skies of Italy and his own untiring zeal. During the oppositions of 1877, 1879–1880, 1881–82, and 1884, the Merz 8½-inch refractor was used, but a start was made in May 1886 with the 18-inch instrument by the same makers, and during the opposition of 1888 this telescope was the one most generally employed. Practical observers will learn with interest that with the former instrument, which the greatest praise is given throughout, a magnification of 322 was most frequently adopted, while a memorandum was made of the fact that a tinted eye-cap of reddish-yellow glass was found to improve definition very materially (vol. 1, pp. 235 and 244).

Judging from these two noble volumes devoted to Schiaparelli's work on Mars, adorned with his portrait and many beautifully reproduced maps and drawings, and printed, moreover, on excellent paper bearing the great man's name watermarked on the lower margin of every page, we may already form some opinion as to the splendour of the literary monument Italy is thus raising to her greatest astronomer. Such an edition as this, as well as the others mentioned at the head of this notice, cannot fail to excite our highest admiration, tempered though it may be with some degree of envy that we in England have no similar edition of the works of Newton to set beside them.

W. ALFRED PARR.

Time and its History.

The Problem of Time: an Historical and Critical Study. By Prof. J. Alexander Gunn. Pp. 460. (London: George Allen and Unwin, Ltd., 1929.) 16s. net.

TIME, which is considered as a necessary element of history, nay, as the very substance of history itself, has now found its own historian. In his lucid and useful book on "The Problem of Time", Prof. Gunn guides us through the slippery paths and thorny places of the mono-dimensional field of time, where the pilgrim meets many extraordinary characters. From the conflicting views of the ever-changing Heraclitus and the immutable Parmenides, to the logical acrobatics of Zeno and the majestic disquisitions of Plato and Aristotle, down to the qualitative meditations of Plotinus, he lands in the medieval conceptions of time. He is shown how Augustine turns from metaphysics to psychology and substitutes discussions on memory and anticipation for past and future; and why Aquinas emphasises the Boetian doctrine of *aevum* as a mean between time and eternity. Then he discovers that the scientific revival of the Renaissance has raised both space and time from being accidental forms or minor entities to the rank of supreme or fundamental realities of the physical world. Here Galileo, Barrow, and Newton, who gave such an importance to time in the mathematical and scientific description of the world, tower over Descartes and Spinoza, who failed to appreciate the full value of time. But soon he assists in the gigantic onslaught against Newton's theory of absolute time perpetrated with psychological and metaphysical weapons by Locke, Berkeley, and Hume, and crowned by the mathematico-philosophical criticisms of Leibniz, who proposes as an alternative his relational theory of time.

Kant, of course, is given a prominent place. In trying to reconcile Newton with Leibniz and to avoid Hume's sceptical remarks, Kant leaves physics behind for transcendental æsthetics. So the pilgrim is shown why time is nothing by itself, but only a form of our intuition, nay, our very inner sense; and how Kant's treatment of time hurls him into his famous antinomies. But while he admires the relations between space and time or between time and phenomena, he is bluntly told that Kant's doctrine of time is highly unsatisfactory and contradictory—a statement soon confirmed by a fine piece of criticism of Kant's views about time. Yet that Kant's statement of problems remained the dominating feature of subsequent thought in western Europe, is shown by the wealth of criticism and alternative theories of his successors, from Hegel and Schopenhauer to Lotze and Cassirer. "The period of Kant and his successors shows a discussion of time as percept and as concept, and a struggle between the subjective and objective viewpoints in relation to time, with increasing stress on objectivity as a feature of time. This struggle has led to the conflict on the field of contemporary metaphysics, with Bergson, on the one hand, denying the existence of objective time and mischievously equating time and our subjective awareness of it, and on the other hand the physicists and the realists

asserting its objective existence, but the physicists limited merely to an interest in its measurement" (p. 340).

The whole position of time in the hurricane stirred up by the theory of relativity is then reviewed in the important chapter on "The Physicists and the Problem of Time-Measurement". Confining himself to his rôle of historian, Prof. Gunn proposes nothing new in his exposition, but his descriptive account of the fate of time tossed between the expert hands of Poincaré, Lorentz, Einstein, Eddington, Langevin, Bergson, Cassirer, Laue, and Schlick, is remarkably illuminating. Yet in his next chapter, on "Time in Contemporary Metaphysics", the philosophical exposition he gives of the doctrines of Whitehead, Russell, and McTaggart is not very satisfactory; while Alexander, Broad, Gentile, and Guyau are very adequately and ably treated. The difficulty about Prof. Whitehead is that his own terminology is not always clear, while the evolution of his views about some fundamental elements of his doctrine often leads to confusion.

Referring to the nature of time in his concluding chapter, Prof. Gunn sketches his own views about this problem, which he distinctly considers as a metaphysical problem. "Neither psychology nor physics attempts to grasp the problem of time in its full significance; the one is merely concerned with our subjective awareness of time and the other confines itself largely to considerations of measurement" (p. 371). According to Prof. Gunn, an inquiry about the nature of time is in effect an inquiry about reality itself; and the true metaphysician must not only regard reality objectively in a way which does not interest the psychologist, but also refuse to formulate a purely mathematical concept in which all qualitative and experiential factors are omitted as unreal. "The metaphysical concept of Time is one in relation to which both the mathematical and psychological concepts can be understood after their kind, but they cannot be equated with it. They separately present a false absolute, an abstraction valid within the respective sciences in which they arise, but misleading if in itself put forward as the sole description of reality. The metaphysician is concerned with the whole" (p. 396).

So Prof. Gunn reveals to us (p. 411) that "Time is an ever-changing present, a sequence of before-and-after objectively given", "a real feature within the Universe", not creating events but created them. He explains also that the concept of time cannot be legitimately divorced from perceptual experience, but that it is bound up with reality; while the whole or total reality is timeless.

A discussion of these provoking assertions would go beyond the compass of this article. But, on the whole, one fails to discover in them any new contribution to the almost exhaustive stock of theories suggested by the protean notion of time. The historical part of the work, however, suggests one or two comments.

Prof. Gunn seems to have misconceived the scholastic views about time, eternity, and eviternity (which should be the adequate term for *Aevum*). He says in a footnote (p. 21) that the scholastics consider real time as the time marked by the events of the heavens. Now, what the scholastics consider as 'real' time, in opposition to 'ideal' time, is the duration of the created objects, including man, it being understood that without an intellect to perceive this duration, no time as such could exist. Real time, therefore, is not confined for them to the motion of heavenly bodies; and further, Aquinas acknowledges in his commentary on "De Coelo" that our description of the universe could be different if we adopted other standards and methods. It is also incorrect to assert (p. 39) that Aquinas refuses his consent to the description of eternity as "interminabilis vitæ tota simul et perfecta possessio" given by Boetius, and which is laboriously explained in quest. X., art. 1, of the "Summa Theologica". As Aquinas begins his discussion by stating the objections to what he wishes to prove, Prof. Gunn has apparently read too hastily that part of the "Summa" which refers to time, taking the objection of Aquinas for his conclusions. As regards the doctrine of eviternity, the concept is ascribed to "incorporeal and heavenly bodies" in so far as they refer exclusively to the angels, whose duration has a beginning but no end, and which is a non-perfect *tota simul*, involving, however, a 'before-and-after'.

Turning to the part played by time in science, it is to be regretted that Prof. Gunn has overlooked the momentous influence of time on the development of mathematics. The timelessness of Greek mathematics, which offered no general method of describing natural phenomena; the genial speculations of Archimedes, who gave such a prominence to time in his devices—but whose name is not mentioned in Prof. Gunn's book; the mathematical discovery of time by the moderns, in their quest to give a more adequate description of Nature; the relations between the notion of

time and the method of tangents which led to the discovery of the calculus; the ontological implications of the mathematical distinction between absolute and relative time, are some of the fundamental problems which ought to have a place in a book about the history of time. Nevertheless, Prof. Gunn must be congratulated for having opened a most fascinating path to those who cannot escape the attraction of the philosophical jungle.

THOMAS GREENWOOD.

A Century of Geography.

The Record of the Royal Geographical Society, 1830–1930. By Dr. Hugh Robert Mill. Published at the Celebration of the Society's Centenary, October 1930. Pp. xvi+288+35 plates. (London: Royal Geographical Society; Edward Stanford, Ltd.; John Murray, 1930.) 10*s*.

IT was a happy choice to entrust the compilation of the record of the Royal Geographical Society's work to Dr. H. R. Mill, with his forty years' experience of the Society and many years' service on its staff. He acknowledges the valued assistance, throughout the work, of Mr. Douglas Freshfield, whose connexion with the Society runs to more than half a century. It cannot have been an easy task to know what to choose and what to omit in the record of the multifarious activities of a Society that was actively interested in practically all the journeys of exploration of its time. Dr. Mill has divided his record into periods of ten or more years, and in each period he has traced the changing fortunes of the Society, given some account of its presidents and other officials, and generally has had to rest content to gauge the work of the time by adding some account of the Society's medallists and the leaders of the expeditions which it has promoted or assisted.

The published journals, proceedings, and other works of the Society and the minute-books of the council have provided the main sources of information. There are many passages recounting heated controversies on lines of policy, told with impartiality and often with a touch of humour; and behind the story is a background of London changing its face and its habits through the years. For the later part of the century Dr. Mill has drawn on his own memories, which have enabled him to give vivid character sketches of many of the men conspicuous in the Society's history. This feature of the book will appeal to many. Some will remember H. W. Bates, the secretary from 1854 until 1892, the "shy and reticent entomologist" who developed powers of insight, judgment, tact, and organisation of a remarkable order. More will recall Sir Clements Markham, who dominated the Society for half a century, a strong but obstinate man, "never able to adjust his mind to scientific modes of thought", and full of narrow prejudices and dislikes, yet warm in friendship and zealous in furthering the interests of the Society. No name connected with the Society is remembered with more regard than that of Sir J. Scott Keltie, for many years librarian, secretary, and editor, a man of unfailing tact and invariable courtesy, and a friend as much to the humble aspirant as to the successful explorer.

Although the Society has always been concerned chiefly with exploration, and almost entirely so in its early days, the furtherance of geographical education was one of the aims of its founders. However, in 1833, three years after its foundation, its council disapproved of a request for "a small endowment" from the University of London for the foundation of a chair of geography to which the Society should have the nomination. In the long reign of Sir R. Murchison as president, from 1851 until 1870, the explorer was supreme in the interests of the Society. Murchison lionised explorers and taught London to do likewise. Thus one side of geography was popularised, but only at the cost of scientific approach. Not until the seventies of last century did other aspects of geography have warm advocates. Sir F. Galton and Mr. D. Freshfield championed a wider outlook. It was Galton who devised and carried through a scheme of school prizes awarded on examination. After sixteen years the scheme was abandoned through lack of interest on the part of schoolmasters. Mr. Freshfield persevered, and by his efforts Mr. J. S. Keltie was employed to report on geographical education in other countries. This report paved the way for the foundation of lectureships, to which the Society contributed generously, at Oxford and Cambridge. The movement at length spread to all the newer universities of England, and the universities of Scotland in time followed suit. Dr. Mill traces these developments, and he might have added that, in the provision of advanced instruction and the institution of honours schools in geography, several of the new universities anticipated Cambridge.

In his final chapter Dr. Mill takes a retrospect of the century in a review of various aspects of the Society's work. These aspects are: growth in number of fellows, finance, collections of books and maps (to which justice cannot be done in a few pages), map production by the Society, instruction

to travellers, and educational activities. An interesting historical chart shows the prosperity curve (total number of fellows) and the popularity curve (annual admissions) through the century, with the duration of each presidency and secretaryship shown. This is full of significance and repays careful study. Two chapters are added by Dr. A. R. Hinks on the Society's War work and a description of the new house which in its enlarged and completed form was opened by the Duke of York on Oct. 21. The volume is illustrated by plates, which include portraits of several of the presidents and other officials, various medals, and the different houses in which the Society has had its headquarters during the century. There is an admirably full index.

R. N. R. B.

Our Bookshelf.

Asia: an Economic and Regional Geography. By Dr. L. Dudley Stamp. Pp. xx + 616. (London: Methuen and Co., Ltd., 1929.) 27*s.* 6*d.* net.

IT is not only the War, with its reconstruction of States and redrawing of frontiers, nor the readjustment of economic relations consequent on these and on the changes which even the most stable countries underwent in their industries and powers of consumption, that make a new survey of the continents necessary and welcome. During the same short period, the study and, most of all, the teaching of geography have been remodelled; even the popular outlook on the world has become geographically orientated in a way which would amaze the pioneer teachers of the previous generation. A mass of recent publications is to hand, and needs fresh guidance if it is to be used as it deserves; and everyone has less time for acquiring exact information which daily becomes more indispensable. A fresh compendium of the geography of Asia, therefore, arouses hopes and challenges criticism.

It is characteristic of the newer geography that it bases its exposition on the reading of maps; and Dr. Dudley Stamp's uses of this 'geographical shorthand' to condense and clarify what he has to say are numerous and often ingenious. It is characteristic, also, that geography is regarded less as a statical presentation of what is, than as an interpretation of what has come to be. If it is not, and cannot strictly be, historical science, its method has at all events much that is akin to that of history. So the book rightly begins with an excellent account of the genesis of the continent, as a clue to its structure and physique; in which stress is laid on the provisional quality of much that is said, and alternative explanations are fairly stated. Geography, further, is an outdoor subject: and Dr. Stamp has travelled widely, in Burma, Malaya, China and Japan, Turkey, Syria and Palestine, and parts of Asiatic Russia. These journeys make possible many vivid touches of description, and a realism of outlook which permits easy handling of a very large mass of information. Occasionally colloquial and lecture-room phrases seem to waste space; but they certainly make the book readable in a way not common among text-books. Where an earlier writer has done justice to a topic, Dr. Stamp, very sensibly, does not hesitate to quote him. The references to literature are carefully selected, and the index is ample.

It is a good test of a book of this kind, that it improves by better acquaintance. A belated review is perhaps none the less useful, if it can certify that this test has been applied: and Dr. Stamp's "Asia" is certainly a very usable book.

Experience and Nature. By John Dewey. (Published on the Foundation established in Memory of Paul Carus.) Pp. ix + ix + 443. (London: George Allen and Unwin, Ltd., 1929.) 12*s.* 6*d.* net.

IN this brilliant and inspiring book, Prof. Dewey attempts to apply in philosophy the thought which is effective in dealing with any genuine question, from the elaborate problems of science to the practical deliberations of daily life. In his opinion, the break between the two realms is the cause of our modern intellectual perplexities and confusions. He is then led to attack the momentous problem of bridging the gap between the intellectual and moral heritage of civilisation, and the material presented to the speculative mind by science, industry, or even politics, by means of what he calls "the method of empirical naturalism".

This method accepts the point of view and conclusions of modern science, and acts like a winnowing fan on the innumerable presentations of experience. What remains after the chaff is blown to the winds is enough to inspire the mind with courage and vitality to create new ideals and values. Prof. Dewey's metaphysical construction is thus based on the conception of the instrumental nature of physical science. Yet he denies the necessity of dividing the objects of experience into a physical and an ideal world, by considering them as linked together by language and other social devices. For example, by regarding life as the link between physical nature and experience, he gives a solution of the mind-body problem which more orthodox philosophers might consider as simply ignoring the whole question. Again, art and values are taken as further proofs of the continuity between nature and experiences by being defined in a pragmatic rather than in an ontological fashion.

On the whole, Prof. Dewey's philosophy is to replace the traditional separation of nature and experience by the idea of continuity. Though refreshing and encouraging in its message, it fails, however, to satisfy our quest for a deeper knowledge of things and values. Prof. Dewey's continuity is immanent rather than transcendental in character so that, although he talks about philosophy all the time, he seems to leave its most critical problems outside the vividly decorated house where he pretends to perform a valid marriage between nature and experience.

The Principles of Photographic Pictorialism. By F. C. Tilney. Pp. x + 218 + 80 plates. (London: Chapman and Hall, Ltd., 1930.) 25*s.* net.

MR. TILNEY is both a painter and a photographer, but above all he is a critic whose writings on photographic subjects during the past twenty years or more have been the best informed and most understanding of any. Whilst this, his latest book, is not specially concerned with photography, in that it does not touch upon any photographic manipulations or processes, it is one that will be of the greatest assistance to all who aspire to make their use of the camera something more than an aimless snapshotting of holiday incidents. It is equally addressed to the student of art and to the lover of Nature, and to both it should bring gain in the intelligent appreciation of the pictorial aspect of their subjects.

After a brief survey of the efforts at picture making in the past and the lessons they convey to us, he goes on to consider the practical points involved in this business of pictorial presentation by photography, and finally deals with certain controversial matters on which he holds firm views that do not always coincide with those held by other photographers. Wisely he begins with a chapter of definitions of the terms used by art critics, in order that there may be no misunderstanding or ambiguity. Thence he goes on to treat of the subject, its choice and design, all the factors relating to composition, beauty of shape, tonal effect, the last a chapter of great value. In the main his observations are based upon landscape, but separate sections are devoted to figures, genre, the nude, portraiture, and still life. The final part deals with what he terms 'problems to some', under which are included halation, colour and panchromatism, perspective (on which he holds emphatic views regarding the difference between the vision of the eye and the lens), and control in printing. The illustrations, drawn from pictures by leading photographers of all times and lands, are in themselves a notable gallery of photographic art. J. DUDLEY JOHNSTON.

Allegemeine Moorgeologie: Einführung in das Gesamtgebiet der Moorkunde. Von Kurd v. Bülow. (Handbuch der Moorkunde, herausgegeben von K. v. Bülow, Band 1.) Pp. xi + 308 + 12 Tafeln. (Berlin: Gebrüder Borntraeger, 1929.) 30 gold marks.

INTEREST in peat has developed greatly in recent years, not only on the applied side of reclamation and utilisation but also on the more purely academic side. Much of the literature on the subject has, however, been inaccessible and diffuse. A "Handbuch der Moorkunde", to appear in ten volumes, will therefore be welcomed. The general editor is K. v. Bülow, of Leba, who has written the volume under review as an introduction, which will undoubtedly appeal to a wider audience than the more specialised volumes to follow. For this reason the treatment is didactic rather than critical, the nomenclature has been simplified, and references to original papers are relatively few.

After a descriptive chapter on the petrographic classification of moors, with many analyses of different kinds of peat, the author deals with modern theories of their origin and development and then proceeds to their stratigraphical morphology and geographical distribution. A preliminary attempt at a world peat map, based on the nomenclature of the Swedish worker, v. Post, shows the close relationships of the different kinds of moor to climatic factors. For Europe there is a fair agreement with the distribution of Meyer's *N.S.* quotient (rainfall divided by absolute saturation deficit). A discussion of Scandinavian work on the division of the Quaternary period by the study of peat profiles leads to an examination of the value of moors as indexes of climatic changes in post-glacial time. This part of the book will appeal to climatologists, geologists, and others.

Simple Research Problems in Chemistry: for Junior Students. By F. Sherwood Taylor. Pp. vii + 100. (London: William Heinemann, Ltd., 1929.) 4*s.*; Answers only, 1*s.* 6*d.*

THE author holds the view that the usual practical training of chemistry students is unsatisfactory, and that "there is a marked tendency for a student to obtain a first-class degree without finding out anything at all". He proposes, as a remedy, to introduce a proportion of research into the school and university courses, so as to train students to a more scientific point of view. The benefit which students get from any practical course is largely dependent on the teacher, and it is questionable whether an unorthodox course such as is here presented would lead to any better results in the hands of a poor teacher than any other. The experiments are good, and one use of the book which suggests itself is to provide exercises for practical examinations. For senior pupils in schools who have been through the usual practical courses it will also provide scope for further work, and all teachers will find Mr. Taylor's book useful and interesting, whatever view they may take of the suitability of the course for the average student. Some of the exercises are suitable for quite advanced students.

An Introduction to the Chemistry of Plant Products. By Dr. Paul Haas and Prof. T. G. Hill. Vol. 2: *Metabolic Processes.* Second edition. Pp. viii + 220. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1929.) 10*s.* 6*d.* net.

THE second edition of this standard work has been largely rewritten and considerably amplified, particularly in the chapters dealing with those sections of plant metabolism which have been undergoing rapid expansion, such as respiration and growth. In the former case, the recent work of Meyerhof, Hill, and F. F. Blackman is combined into a unified scheme of considerable value. The rather brief section in the first edition dealing with nitrogen metabolism has also been enlarged by a detailed discussion of nitrate reduction. The authors have exercised a wise choice in their amplifications and the value of the book is greatly increased throughout.

Spectrographic Analysis of Animal Tissues.

IN NATURE of April 20, 1929 (**123**, p. 601), one of us (H. R.) described a method of spectrographic analysis of mineral and organic substances and pointed out the value of the method for biological purposes. Since then we have undertaken a survey of the animal kingdom with the purpose of detecting and analysing quantitatively those of the less common elements contained in protoplasm and its products which can be investigated by this method.

The animals, if small, are minced whole, or if sufficiently large are dissected and the separate organs minced. The material is then dried at 100° C., powdered in an agate mortar, and a weighed quantity (50 mgm.) taken and rolled in ashless filter paper. The roll is burnt in an oxy-coal gas flame in front of the slit of a quartz spectrograph, the image of the flame being focused on the slit by a quartz lens. The spectrum is recorded on a photographic plate. In the case of liquids, such as blood, 0·1 c.c. is pipetted on to a rolled filter paper, which is then burnt as described.

The method has been developed quantitatively. A standard solution has been prepared containing the various elements in known quantities. Four different volumes of this solution are burnt on filter paper and the resulting spectra photographed on each plate on which the tissue spectra are recorded. The intensity of a given line in a tissue spectrum can then be matched with the corresponding line on one of the standard spectra, and the quantity of the element concerned can consequently be deduced.

Spectrographic analysis has hitherto only been applied to animal tissues in a few isolated investigations. Yet the method is obviously of great value, for a wide survey of tissue contents can be made with a rapidity impossible with chemical methods. We have commenced our investigations with annelids (analysed whole), molluscs (separate organs studied), and a few members of other phyla. Already a number of important new facts have emerged. The most salient are the following.

Iron and copper were present in all of the 146 different spectrograms made. The wide distribution of iron in protoplasm is already known, and its functional importance has been emphasised by Keilin's work on cytochrome (*Proc. Roy. Soc.*, B, **98**, 312; 1925). Copper has previously been found in numerous animal tissues and it has at least two functions, namely, as a component of the hæmocyanin molecule, and as an essential factor in hæmoglobin synthesis (Waddell, *J. Biol. Ch.*, **84**, 115; 1929, and others). When whole animals were used for our work, it is possible that elements which appeared in the spectra were in the gut or on the skin, and, of course, in the case of molluscs, copper exists in hæmocyanin. Nevertheless, the invariable presence of iron and copper strongly suggests that these are universal constituents of protoplasm.

Manganese was found in all nineteen species of polychætes studied. It was widely distributed in the molluscs, being present, for example, in all organs of land gastropods. It was found in numerous organs of marine gastropods, but was absent from *Haliotis*. The quantity in an organ varied with locality. Manganese is known to stimulate growth of rodents (McHargue, *Am. J. Physiol.*, **77**, 245; 1926. Bertrand and Nakamura, *C. R. Ac. Sci.*, **186**, 1480; 1928). When our survey has extended further, indications may be given of other functions. Harrison and Garrett (*Proc. Roy. Soc.*, B, **99**, 241; 1926) induced melanism in Lepidoptera by manganese feeding. We do not find this element particularly associated with melanin. The spectrum of the ink sac of *Sepia* shows none, and while manganese is strong in the black body-wall of *Arion ater* (0·008 per cent of dry weight), there is even more in the colourless common genital duct.

Nickel and cobalt were present in certain tissues. Cobalt was less common than nickel, and was usually associated with a relatively high concentration of the latter. But the foot of *Haliotis* has a high nickel content (0·004 per cent) without cobalt, while the liver of *Archidoris tuberculata* contains cobalt (0·003 per cent) with no nickel. There is thus a selective absorption.

Lead and silver occur spasmodically but not infrequently. The strongest silver was in the liver and kidney of *Pinna pectinata*. Individuals and individual organs absorb these metals selectively, for unknown reasons. One human subject had silver in all organs, while two others had none. Lead was present in different organs in each of the three men. This suggests an absence of functional significance.

Cadmium was found in the livers of all the eleven individuals of *Pecten maximus* examined. They came from three different localities. This seems to be the first record of cadmium in an animal.

Lithium turned out to be very widespread in animal tissues. Rubidium is less common. Cæsium was not found. This is remarkable, since rubidium and cæsium both enter frog's muscle from a perfusion fluid (Mitchell, Wilson, and Stanton: *J. Gen. Physiol.*, **4**, 141; 1921), and cæsium is present in sea water.

Strontium was present in 17 out of 19 species of polychætes and in 51 out of 67 tissues of molluscs. Previously it was known only from the skeleton of a radiolarian and from marine shells. Barium, on the other hand, was absent.

Calcium fluoride was found in one tissue only, namely, the body wall of *Archidoris tuberculata*.

A detailed account of the work will be published shortly.

Experiments on Binaural Sensations.

AT intervals during the past five years I have been attempting a survey of the various experiments which have been taken as evidence that binaural sensations with musical notes of low pitch are due to the appreciation of phase differences produced at the ears. The work grew out of some experiments with sound waves which are recorded in the *Proceedings of the Physical Society* for August 1927.

Repetition of the various experiments has driven me to the conclusion that, with the forms of apparatus used, there have been possibilities of intensity change and I do not think that these possible alterations have been sufficiently taken account of in the interpretation of some of the published results. It is very difficult to produce the binaural sensation of change of position of the sound 'image' under conditions where it can be shown that phase differences are set up without any accompanying alterations of intensity. Change

of intensity produced by common forms of apparatus are found, when actually measured, to be surprisingly large and may well be an important factor in producing the binaural effect.

The experiments with two valve oscillators, which have been interpreted as favouring the phase difference localisation theory, depend on the known fact that, when the frequency of one oscillator is adjusted by a tuning condenser over the range for which the sets are in unison, the phase difference of the electrical oscillations, and also of the telephone diaphragm movements, alters from 0 to π. Two telephones, energised one from each oscillator, are worn over the observer's ears and he adjusts the loudness of the sound in each ear by means of two shunts. With this arrangement the sensation of rotation can be obtained either when the two circuits are nearly but not quite in tune or when the tuning condenser has its adjustment altered within the unison range.

I have made measurements both of the amplitude of the oscillatory currents and of the amplitude of the telephone diaphragm movements under these conditions and both show changes. The variations depend on the degree of coupling between the circuits, and when the amplitude is increasing in one telephone it is decreasing in the other. Thus an intensity effect is present which will aid the sense of localisation of the sound. It is possible, moreover, to produce similar intensity variations under conditions where no phase differences are present at the ears. When this is done, the sensation produced seems very like the ordinary binaural rotation.

In experiments on binaural beats it is evident that, when this form of apparatus is used, great care must be taken to eliminate all possibility of these oscillatory current variations before any conclusions are drawn about the so-called 'subjective' beats.

When sound from one source is led by two paths of adjustable length to the two ears, again experiment shows that measurable variations of intensity may occur at the ears. It would seem therefore that, until such variations have been eliminated, this method does not give conclusive evidence in favour of phase difference as the main factor in binaural localisation.

Experiments with two tuning forks producing slow beats seem to be open to criticism along similar lines.

I think that the induced currents produced in a 'phasor' when it is used to give binaural effects must be tested also for possible intensity variations. May I ask someone who possesses such a phasor with which binaural effects have been observed, if he will allow me to borrow the instrument to make measurements of the induced currents? Experiments already made with an apparatus of this type have shown that it is not easy to introduce phase difference by moving one of the coils without producing, at the same time, changes in the magnitude of the currents.

It is hoped that full details of the experiments will be ready for publication in the next few months.

Observations on the Mechanism of Spore Formation.

DURING the investigation of a spore-bearing organism isolated from heated milk, certain morphological changes prior to sporulation were observed. The observations recorded were made upon fixed preparations stained by Moeller's spore-staining technique and by Giemsa's stain, and upon unfixed preparations stained by Nakanishi's method. The results were confirmed by dark ground examination of the living organisms.

Germination of spores takes place rapidly under suitable conditions and an actively-dividing vegetative phase ensues. In this phase the cells show dense protoplasmic contents which stain readily with the basic aniline dyes (Fig. 1, i). Later, the contents become less dense, and as the time for spore formation approaches, become distinctly granular. After thirty-six to forty-eight hours' incubation a characteristic stage may be observed in which an unstained area is lying towards one end of each cell, cutting off and isolating a definite terminal part of the cell contents (ii). This terminal portion is the potential spore and its position is fixed at this stage of the development. The remainder of the cell contents, meanwhile, have shown definite signs of contraction (iii) and finally condense to form a second body, which we have called the 'secondary granule' in order to distinguish it from the 'terminal or spore granule'. The appearance of the organism at this stage is quite characteristic (iv). It consists of a swollen, practically unstained envelope within which lie the two granules, deeply stained, one terminal in position, the other

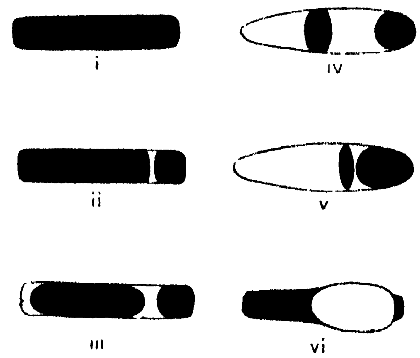

FIG. 1.

median or excentric. At a slightly later stage the position of the 'secondary granule' is seen to vary somewhat in different cells. In a definite proportion of cases, however, it is oval or lens-shaped and lies closely adjacent to the 'terminal granule' (v). Whether there is any actual contact between them has not yet been established, but it is of interest to note that it is in such cells that the first indication of a spore wall is visible, and that as soon as this wall begins to form, the staining and refractive properties of the 'spore granule' become those of a true spore. The fate of the 'secondary granule' is uncertain, but it would seem from careful observations that, having played some part in the development of the spore, it disperses throughout the body of the mother cell, which then resumes its ordinary staining capacity (vi).

A study of the literature, particularly the work of Schaudinn (1902), Guilliermond (1908), Swellengrebel (1913), Bessubetz (1913), and many others, shows that various nuclear processes have been previously recorded in connexion with spore formation. Whether any analogy exists between these findings and the present case is a point which can only be established by further and more detailed work, but there remains the strong suggestion that, as spore formation is preceded by the sequence of morphological changes recorded, some nuclear process may well be involved.

Injury to Plaster due to Osmosis.

FROM time to time, it has been suggested that osmosis plays a part in the weathering of building materials. A note on a failure of plaster work for which osmotic action is directly responsible may therefore be of interest.

Brick walls are sometimes found to which lime plaster cannot be made to adhere permanently. Some time after the plaster is applied it commences to bulge and finally is pushed off the wall. Immediately behind the face of the brick is found a columnar crystalline growth which, in all cases so far examined, proves to be magnesium sulphate ($MgSO_4 7H_2O$) in a practically pure condition.

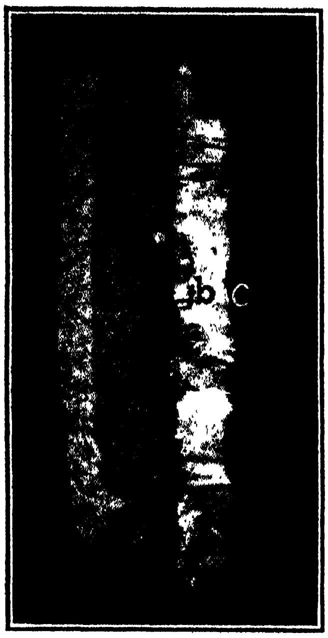

FIG. 1.—(*a*) Lime plaster; (*b*) magnesium sulphate; (*c*) brick

It now appears that, when lime plaster is applied to bricks containing a proportion of magnesium sulphate, a semi-permeable membrane is precipitated in the face of the bricks. As the plastered wall dries out, magnesium sulphate is drawn from the body of the bricks, concentrates behind the membrane, and then crystallises, forcing the plaster and a thin shell of brick away from the wall.

It has been found possible to precipitate membranes of magnesium hydroxide in the walls of porous pots. Using a half-saturated solution of magnesium sulphate, osmotic pressures so high as 100 cm. of water were developed in three days.

In Fig. 1 is shown the magnesium sulphate growth (*b*) between the plaster (*a*) and the main body of the brick (*c*). To the left of the layer of magnesium sulphate the thin layer of brick which supports the osmotic membrane may be seen.

The Zeeman Effect and the Absorption Coefficients of the Hyperfine Structure Components of the Mercury Resonance Line.

THE investigations of McNair (*Phys. Review*, **31**, 986; 1928) have shown the complicated behaviour of the Zeeman patterns of the mercury resonance line, 2537 A., in emission. Some observations made in absorption five years ago by Wood appear to be in contradiction with the results of McNair. To clear up this difficulty I have made a more systematic study of the Zeeman effect of the mercury resonance line in absorption for magnetic fields from zero to 8 kilogauss and have obtained the following results:

The parallel components in absorption behave similarly to those in emission, with the exception of moderate intensities of the magnetic field, 1-3 kg., when, besides the five components, the light of intermediate wave-lengths is also absorbed. The scheme of McNair does not quite suffice to explain the behaviour of the components perpendicular to the field, because the – 10·4 and + 21·5 mA. components (transmitted through the absorbing vapour in the magnetic field) show for certain intensities of field an anomalous behaviour, not understandable from the point of view of McNair. However, generally speaking, the results of my investigations can be reconciled with the results of McNair rather than with the eventual existence of a Paschen-Back effect, and they lead to fairly good interpretation of the curve giving the intensity of transmitted light as a function of the field intensity, which was obtained two years ago by Schein.

These investigations have further shown that, for certain intensities of the field, the vapour transmits: (α) only the outer short wave-length component, – 25·4 mA., or (β) one inner and one outer component, – 10·4 and + 21·5 mA., or (γ) two inner components, 0 and + 11·5 mA. The absorption coefficients of the radiation, which was monochromatised in this way, was estimated by means of the decrease of the intensity of the resonance radiation along the beam. The measurements were made for the temperatures 0° and 16½° C. and have given the results: β = 1·25 · γ – 1·60; which are in agreement with the estimates of intensity in emission lines made by Miss Schrammen. The estimated values of the absorption coefficients, which are less certain than the relative ones, computed in the ordinary way for the temperature 20° C. from the measurements made at 0° C., are: $\alpha = 3{\cdot}3$; $\beta = 4{\cdot}0$; $\gamma = 5{\cdot}1$ cm.$^{-1}$. The estimated value for all five components, $k_{20} = 4{\cdot}2$ cm.$^{-1}$, which differs only little from the average of the valu $\alpha + 2\beta + 2\gamma$ less than that obtained from the photoelectric measurements (Kunze, Kopferman and Tietze, Zemansky), probably because I was not able to extend my measurements close enough to the window through which the exciting light enters into the resonance vessel.

A full report of these investigations will appear in the *Bulletin de l'Académie polonaise* (Cracow).

Two Modifications of Liquid Ethyl Ether.

THE changes of the dielectric constant of liquid ethyl ether with temperature studied by one of us (J. M.), and described in a recent communication in NATURE, suggest that at the temperature 105·4° C. the liquid undergoes some transformations analogous to that found for liquid helium by W. Keesom and M. Wolfke (*Comm. Leiden*, 190 *b*). To confirm this supposition

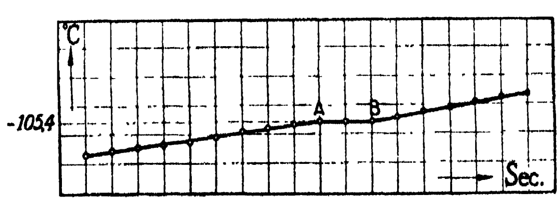

FIG. 1.

we have made a study of the change of temperature with time during the gradual heating of carefully purified ethyl ether.

Ethyl ether cooled to a temperature lower than – 105·4° C. was contained in a Dewar vessel provided with a nickel covered refrigerator cooled with liquid air. We have studied the change with time of gradually increasing temperature of the ether, which was

isolated from all external disturbances. The platinum resistance thermometer was used as a stirrer.

The accompanying graph (Fig. 1) representing these observations shows a distinct slowing down of the rate of change of temperature at $-105 \cdot 4^\circ$ C. (see the part A B of the curve). The transformation point is very clearly indicated in this heating curve. The parts of curve above and below the point $-105 \cdot 4^\circ$ C. are to a high degree of approximation straight lines, making different angles with the temperature axis, which shows that the specific heat of ethyl ether undergoes a change at $-105 \cdot 4^\circ$ C.

The transformation of liquid ether described above is the second observed case of such a phenomenon, the first one being the discovery of liquid helium I. and helium II. by W. Keesom and M. Wolfke (*Comm. Leiden*, 190 *b*).

The Development of the Mesoderm in Gastropods.

IN 1891 Erlanger reported that in the freshwater snail *Paludina* the mesoderm was formed as a hollow pouch budded out from the primitive gut or archenteron. From a portion of this pouch, which may be regarded as the secondary body-cavity or cœlom, the pericardial sac was formed. Such a mode of the formation of the cœlom, though normal in Echinodermata and Chætognatha and also in *Amphioxus* and the Enteropneusta, was hitherto unknown in Mollusca, and Erlanger's results were received with a storm of scepticism. Later, Tönniges (1896) examined the development of *Paludina* and denied the validity of Erlanger's results, and asserted that the mesoderm arose as small cells budded from the ectoderm. The most recent worker on the subject (Dautert, 1929) has confirmed Tönniges's conclusions.

It seemed as if Erlanger had been utterly discredited. During this summer Mr. Fernando, a student working in my laboratory, re-examined *Paludina*. He found all the stages figured by Erlanger and completely confirmed his results. But he also found the stages figured by Dautert and Tönniges and showed that the differing results of these two workers were due to the old embryological error of missing out stages in development.

Fernando's results may serve as a warning against accepting negative results in zoology. Positive results are a definite addition to our knowledge: they may be misinterpreted and later workers may supply better interpretations, but negative results which suggest that positive results are entirely imaginary are almost always due to defective observation.

Vitamin A and Carotene.

RECENT work by Moore and others (see, for example, Moore, *Biochem. Jour.*, **24**, 692; 1930) has left little doubt that, in the rat, carotene can function as a precursor of vitamin A. Experiments which I have just carried out have indicated that the same holds true in the fowl also. White Leghorn chickens, six weeks old, were given a synthetic diet free from vitamin A to which irradiated ergosterol was added to supply vitamin D. Control birds receiving this diet succumbed in about six weeks, their livers giving negative tests for vitamin A either by the antimony chloride test or by the absorption spectrum. To other birds, after a preliminary period of vitamin A depletion, daily doses of carotene (1 mgm.) or cod liver oil concentrate (10 mgm.) were given, with the result that complete cures were effected and satisfactory growth restored. The livers of all these birds, receiving either carotene or concentrate, gave positive tests for vitamin A, the oils yielding an intense blue colour with antimony chloride and showing a strong absorption band in the region of 328 $\mu\mu$.

As well as indicating that the ability to transmute carotene into vitamin A may hold fairly generally throughout the animal kingdom, the experiments would seem to afford an explanation of the results of Palmer and Kempster (*Jour. Biol. Chem.*, **39**, 331; 1919), who found that while xanthophyll fed to fowl reared on a diet free from carotenoids quickly increased their pigmentation, carotene had no such effect. The transmutation of carotene into the colourless vitamin A would account for this very simply.

A full account of the experiments will be published elsewhere.

Denaturation of Proteins by Urea.

THE important article by Sir Frederick G. Hopkins which appeared in NATURE on Aug. 30 and Sept. 6 records many valuable new observations on which he is to be congratulated. It has, indeed, only one defect, and, at his request, I write to make that good, namely, the absence of all reference to the observations made many years ago by myself and my delightful friend Dr. N. G. Chavasse, a man who was twice awarded the V.C., and whose loss is to me one of the major tragedies of the War. The fact that Sir Frederick knew nothing of these observations is, however, very intelligible, since the first paper (*Jour. of Physiol.*, **28**, pp. 23-26; 1902) appeared obscurely in the *Proceedings*, only, of the Society concerned, and the second (*Proc. Faraday Soc.*, March 1913; German translation in *Zeits. f. Kolloide*, **12**, pp. 250-252; 1913) was entitled "Graded Protein Sols".

Let me add that during the last two years Mr. J. Hatton has been working on this subject under my supervision, and that in 1929 we found, like Sir Frederick, that the rate of denaturation of approximately isoelectric egg-albumin by urea had a negative temperature coefficient. Other results of ours will now be found in the Proceedings of the Biochemical Society published in *Chemistry and Industry*, Oct. 10, 1930, p. 851. That account should be supplemented by the statement that, in the case of sheeps' wool, much, though apparently not all, of the substances the thiol or disulphide groups of which have become 'unmasked' passes into the urea solution.

Oviposition of *Hæmatopota pluvialis*, Linné.

DR. CAMERON's interesting account, in NATURE of Oct. 18, p. 601, of the oviposition habits of Tabanid flies, and especially of those of *Hæmatopota pluvialis*, L., suggests that the following observation may be worth recording. On Aug. 24, 1925, at Waidbruck (Ponte all' Isarco), Italian Tyrol, I observed a female of *Tabanus glaucopis*, Mg., laying her eggs on the leaves of the common plantain, *Plantago lanceolata*. The plant was growing in a dry hay-field, not in the immediate vicinity of water.

The Biological Significance of Conjugate Nuclei in *Coprinus lagopus* and other Hymenomycetes.*

By Prof. A. H. REGINALD BULLER, F.R.S.

CONJUGATE nuclei are two nuclei of opposite sex, associated with one another in a single cell, which divide sumultaneously in such a way as to give rise to two daughter pairs of conjugate nuclei. Stages in conjugate nuclear division in *Coprinus lagopus*, based on the work of Mlle. Bensaude, are shown in Fig. 7.

In animals conjugate nuclei are unknown and in plants their occurrence is limited to the Higher Fungi. They especially characterise the diploid mycelium and fruit-bodies of the Hymenomycetes (Mushrooms and Toadstools) and the diploid mycelium of the Rust Fungi and the Smut Fungi, all of which groups are included in the larger assemblage of the Basidiomycetes. Conjugate nuclei are also present in the ascogenous hyphæ of certain Ascomycetes.

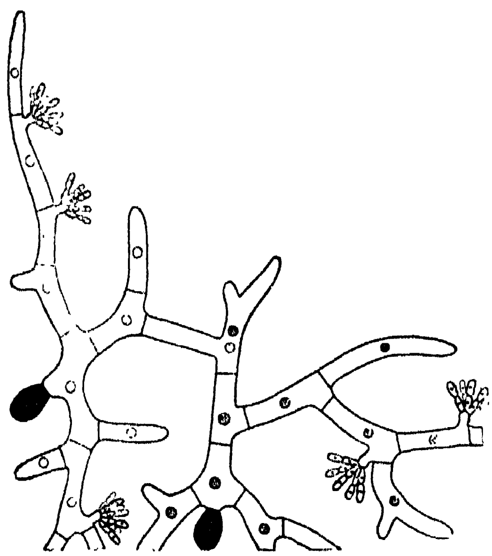

FIG. 1.—*Coprinus lagopus*. Diagram showing two *haploid* mycelia of opposite sex, (*AB*) on right (black nuclei), (*ab*) on left (white nuclei), each derived from a single basidiospore. Note the simple septa, the groups of oidia, and the isolated nuclei. The two mycelia have just effected a hyphal fusion and in the fusion cell an (*AB*) nucleus and an (*ab*) nucleus have become associated as a pair of conjugate nuclei. The diploid cell is able to diploidise all the other cells of both mycelia by a process illustrated in Fig. 6.

Coprinus lagopus is a small toadstool of common occurrence on horse dung in pastures. Its pilei shed numerous black basidiospores which are carried off by the wind, settle on grass, etc., are swallowed with herbage by horses, and germinate in freshly deposited dung-balls. In these dung-balls haploid mycelia of opposite sex mate with one another and form diploid mycelia. The diploid mycelia give rise to diploid fruit-bodies which produce and liberate haploid basidiospores. The life-cycle from spore to spore is carried through in 10-14 days.

As determined by Hanna,[1] Dorothy Newton,[2] and others, the monosporous mycelia (each derived from a single basidiospore) of *Coprinus lagopus* fall into four groups. If it be assumed that each mycelium bears one of each of two pairs of sex factors, *Aa* and *Bb*, then the four groups of mycelia and the four groups of spores from which they have been derived may be represented by the symbols (*AB*), (*ab*), (*Ab*), and (*aB*).

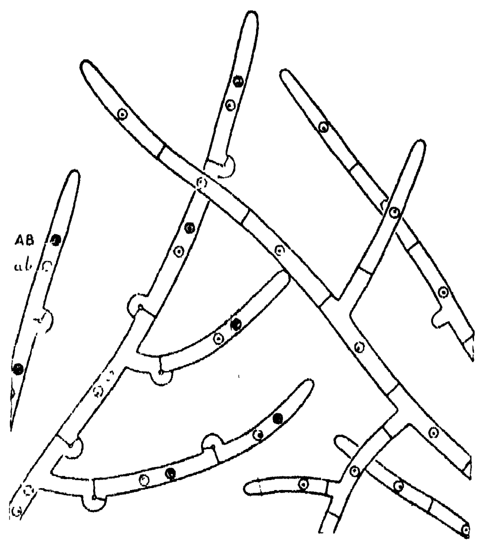

FIG. 2. *Coprinus lagopus*. A diploid mycelium (*AB*) + (*ab*) on the left, and a haploid mycelium (*ab*) on the right. In the diploid mycelium, note the pairs of conjugate nuclei of opposite sex [illegible] each cell and the clamp-connexion at each septum. A ce[illegible] hypha of the diploid mycelium is about to fuse [illegible] hyp[illegible] the haploid mycelium. The diploid mycelium, after the [illegible] was effected, would begin to diploidise the haploid mycelium.

Successful mating of the haploid mycelia of *Coprinus lagopus* with the production of a diploid mycelium (bearing clamp-connexions and containing a conjugate pair of nuclei in each cell) is normally possible only in the combinations (*AB*) × (*ab*) and (*Ab*) × (*aB*). These two kinds of combinations give rise to two kinds of diploid mycelia which may be represented by the symbols (*AB*) + (*ab*) and (*Ab*) + (*aB*) respectively.

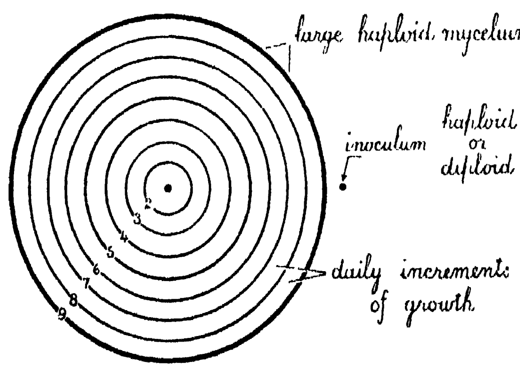

FIG. 3.—*Coprinus lagopus*. A large haploid mycelium which has been growing for 9 days on dung-agar. A tiny hyphal mass of another haploid mycelium of opposite sex or of a suitable diploid mycelium, called the *inoculum*, has just been set a little way from the periphery of the large haploid mycelium. Two-thirds the actual size.

Haploid mycelia (Fig. 1) are known by containing single isolated nuclei, by having simple septa devoid of clamp-connexions, by the wide-angled mode of branching of their leading hyphæ, and by bearing oidia. Diploid mycelia (Fig, 2,

* Substance of a paper communicated to a meeting of the Fifth International Botanical Congress at Cambridge, Aug. 19, 1930.

left) are known by their cells containing pairs of conjugate nuclei, by having a clamp-connexion at each septum, by the narrow-angled mode of branching of their leading hyphæ, and by not bearing oidia. Clamp-connexions, as shown by the cytological investigations of Mlle. Bensaude, Hans Kniep, and others, are the outward and visible sign that the adjacent cells are diploid in that these cells contain a pair of nuclei of opposite sex.

A large haploid mycelium (*AB*), which had been growing on a dung-agar plate for 9 days (cf. Fig. 3), was inoculated with a small hyphal mass of a haploid mycelium (*ab*). The two mycelia soon fused hyphally and mutually *diploidised* one another, that is, (*ab*) nuclei entered the mycelium (*AB*), divided and subdivided, and established pairs of conjugate nuclei (*AB*) + (*ab*) in every cell of the peripheral hyphæ of (*AB*), while (*AB*) nuclei entered the mycelium (*ab*), divided and subdivided, and established pairs of conjugate nuclei (*AB*) + (*ab*) in every cell of the peripheral hyphæ of (*ab*). This was indicated by the appearance of clamp-connexions. In the large haploid mycelium (*AB*), clamp-connexions appeared on the (*AB*) hyphæ on each side of the inoculum (*ab*) progressively (*see* crosses in Fig. 4): and the diploidisation† of the (*AB*) mycelium was effected in the course of three days. In 42 hours after the (*ab*) inoculum had been deposited and about 40 hours after the (*ab*) and (*AB*) mycelia had come into contact with one another, clamp-connexions had appeared at a distance of 6 cm. or 60 mm. from the inoculum. Therefore (*ab*) nuclei must have moved through the hyphæ of the (*AB*) mycelium at an average rate of at least 1·5 mm. per hour. The nuclei could not move in a straight line like that shown in Fig. 4, because the mycelium (*AB*) was a three-dimensional hyphal net-work. The (*ab*) nuclei must have taken a zigzag path and, therefore, their speed of movement doubtless exceeded 2 mm. per hour. As Lehfeldt's cytological work on *Typhula erythropus* has shown,[3] the septa of a haploid mycelium undergoing diploidisation break down and thus allow nuclei to pass along the hyphæ.

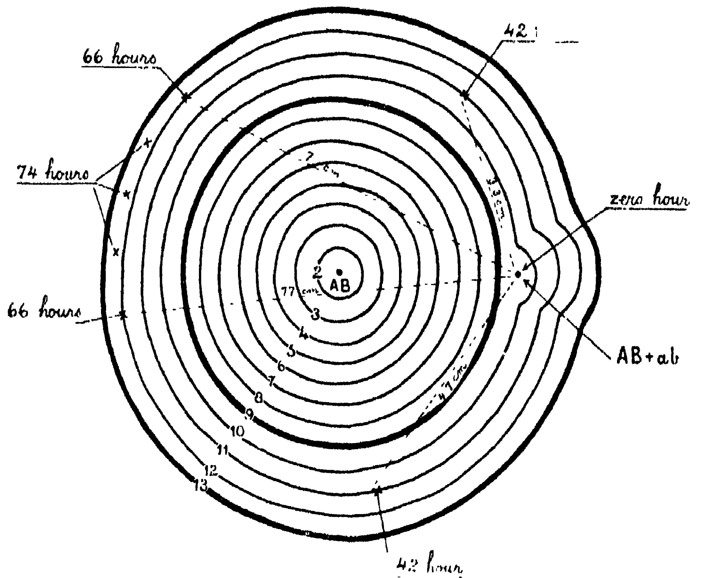

FIG. 5.—The diploidisation of a large haploid mycelium (*AB*) by a *diploid* mycelium (*AB*) + (*ab*). The (*AB*) mycelium was inoculated with a tiny hyphal mass of the (*AB*) + (*ab*) mycelium after 9 days of growth (periphery shown by heavier inner circle, No. 9) at the zero hour. The diploid mycelium diploidised the haploid mycelium in a little more than three days. The crosses show where clamp-connexions were observed at particular times. The (*ab*) nuclei must have travelled more than 7·7 cm. or 77 mm. through the (*AB*) hyphæ in about 64 hours, or more than 1·2 mm. per hour. Two-thirds the actual size.

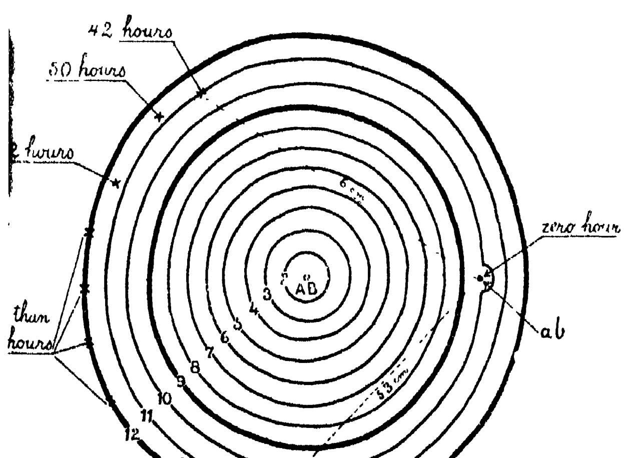

FIG. 4.—The diploidisation of a large haploid mycelium (*AB*) by another *haploid* mycelium (*ab*) of opposite sex. The circles 2-12, originally drawn in blue pencil on the under side of the Petri dish, show the boundary of the mycelium from the end of the second to the end of the twelfth day. The (*AB*) mycelium was inoculated with a tiny hyphal mass of an (*ab*) mycelium after 9 days of growth (periphery shown by heavier inner circle, No. 9) at the zero hour. The (*ab*) mycelium diploidised the (*AB*) mycelium in the course of three days. The crosses show where clamp-connexions were observed at particular times. The (*ab*) nuclei must have travelled more than 6 cm. or 60 mm. through the (*AB*) hyphæ in about 40 hours, or more than 1·5 mm. per hour. Two-thirds the actual size.

The radial rate of growth of the (*AB*) mycelium of Fig. 4 was 0·15 mm. per hour. Therefore the rate of movement of the (*ab*) nuclei along the hyphæ of the (*AB*) mycelium —upwards of 2·0 mm. per hour—was more than thirteen times the rate of elongation of the leading radial (*AB*) hyphæ.

Fig. 5 illustrates an experiment similar to that just described, except for the important fact that a *diploid* inoculum was employed instead of a haploid. The combination was a large haploid mycelium (*AB*) and a small diploid inoculum (*AB*) + (*ab*). Again the large haploid mycelium was progressively diploidised. In this case, doubtless, (*ab*) nuclei left the diploid inoculum, entered the (*AB*) mycelium, there divided and subdivided, and so provided mates

† The term *diploidisation* has been introduced here for the first time to designate the process by which a haploid cell is converted into a diploid cell or a haploid mycelium into a diploid mycelium by the formation of conjugate nuclei within the cell's or the mycelium's interior. A haploid mycelium of one sex may be said to *diploidise* a haploid mycelium of opposite sex.

to form conjugate pairs with all the (AB) nuclei in the peripheral hyphæ of the (AB) mycelium.

It has been found that a diploid mycelium $(AB)+(ab)$ can rapidly diploidise a haploid mycelium (AB) or a haploid mycelium (ab); and also that a

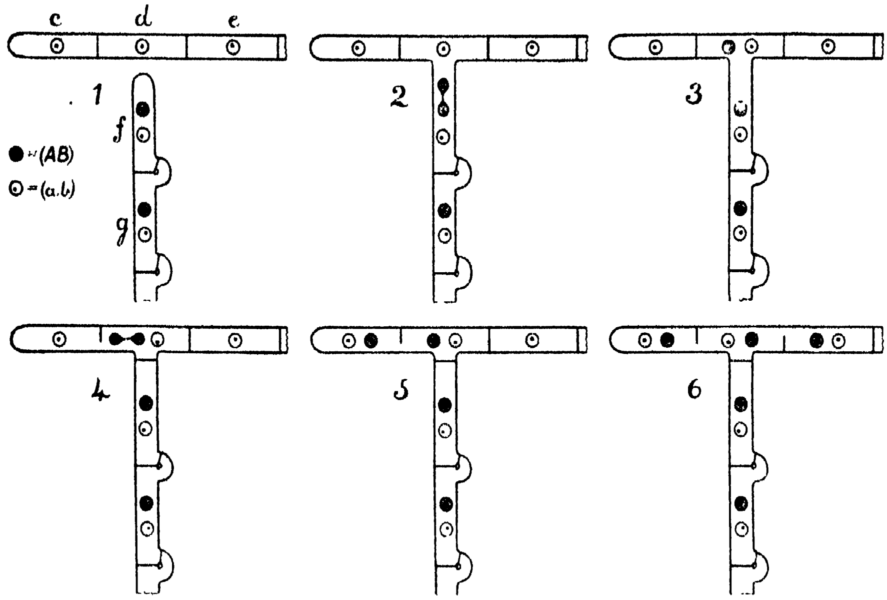

FIG. 6.—Diagram to show the diploidisation of a haploid mycelium (ab) by a *diploid* mycelium $(AB)+(ab)$. No. 1: the cell f of the diploid hypha fg is growing toward, and soon will meet and fuse with, the cell d of the haploid hypha cde. No. 2: fusion has taken place and the (AB) nucleus of f is dividing. No. 3: one of the daughter (AB) nuclei has passed into the cell d, thus diploidising it. No. 4: a wall now separates the cells d and f, and the (AB) nucleus in the cell d is dividing. No. 5: the wall between the cells c and d is partly broken down and one of the daughter (AB) nuclei has passed through it from d to c. No. 6: the (AB) nucleus of the cell d has again divided and sent one of its daughter (AB) nuclei into the cell c. Thus the diploid cell f diploidised the haploid cell d and the diploid cell d in its turn diploidised first the haploid cell c and then the haploid cell e.

diploid mycelium $(Ab)+(aB)$ can rapidly diploidise a haploid mycelium (Ab) or a haploid mycelium (aB).

The discovery that a diploid mycelium can diploidise an appropriate haploid mycelium is of considerable interest from two points of view: (1) It indicates that, in *Coprinus lagopus* and other similar fungi, the normal matings in dung-balls, wood, and other substrata in Nature are not merely the haploid matings $(AB)\times(ab)$ and $(Ab)\times(aB)$ but are also the haploid-diploid matings $(AB)\times(AB)+(ab)$, $(ab)\times(AB)+(ab)$, $(Ab)\times(Ab)+(aB)$, and $(aB)\times(Ab)+(aB)$; and (2) it also indicates that a diploid cell containing a pair of conjugate nuclei can diploidise a haploid cell containing a single nucleus, and thus gives us a clue to the biological significance of conjugate nuclei. This last point will now be discussed.

When, in a haploid-diploid combination, a diploid cell containing a pair of conjugate nuclei, say $(AB)+(ab)$, comes into contact with a haploid cell containing a single nucleus, say (ab), doubtless the (AB) nucleus—possibly in response to a stimulus received from the unpaired (ab) nucleus—*divides* and sends off one of the daughter nuclei into the haploid cell (Fig. 6, stages 2 and 3). Thus, in a very simple way, a diploid cell can diploidise a haploid cell. Doubtless, also, when a large haploid mycelium has been inoculated with a tiny hyphal haploid inoculum of opposite sex, the progressive diploidisation of the large haploid mycelium is due essentially to the fact that a diploid cell is able to diploidise neighbouring haploid cells in the manner just suggested (cf. Fig. 6, stages 3-6).

If, when a large haploid mycelium (AB) made a hyphal fusion with a small haploid inoculum of opposite sex (ab), an (ab) nucleus on passing into an (AB) cell immediately fused with the (AB) nucleus there present, an $(AaBb)$ nucleus would result and progressive diploidisation of the thousands of other (AB) cells the (AB) nuclei of which awaited partners would be impossible. However, since the (ab) nucleus is attracted by, but does not fuse with, the first (AB) nucleus it meets, it is possible for it to divide and send off a daughter (ab) nucleus into the next haploid (AB) cell and thus contribute to the diploidisation process.

The organisation of the nuclei in conjugate pairs $(n)+(n)$ instead of as isolated nuclei $(2n)$ i the diploid myceliu a fruit-body of *Coprin lagopus* and oth Hymenomycetes results, it is true, in delayi the fusion of nuclei of opposite sex until t

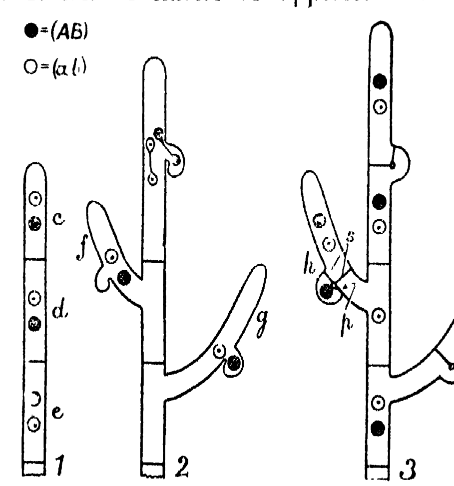

FIG. 7.—Diagram to show how a haploid hypha after it has just been diploidised develops further. No 1: a haploid hypha (ab) or (AB) which has just been converted into a diploid hypha $(AB)+(ab)$; a pair of conjugate nuclei are present in each cell. No. 2: the cells d and e have branched and the cell c has elongated; in f a hook has grown backwards; in g an (AB) nucleus has passed into the hook; in the terminal cell c, the two nuclei are dividing conjugately and the hook is growing toward the main hypha. No. 3: in the branch f the two daughter pairs of conjugate nuclei have separated from one another and two septa s have been formed, but the lower (AB) nucleus is momentarily a prisoner in the hook-cell h, from which it will escape as soon as the walls at p have broken down; in the branch g and the terminal cell c conjugate nuclear division and cell-division with the formation of a clamp-connexion is complete and each daughter cell contains a pair of conjugate nuclei (AB) and (ab).

basidia come into existence, but it has the great advantage that, in the diploid mycelium or in a diploid cell of a haploid mycelium under-

going diploidisation, each member of a pair of conjugate nuclei retains its identity, so that one member of a pair can divide independently of the other member of the pair whenever such a division is able to promote the diploidisation of another haploid mycelium or of an adjacent haploid cell.

The sexual process (fertilisation or conjugation) of animals and most plants is relatively simple in that two *unicellular* and *uninucleate* gametes fuse to form a unicellular and uninuclear zygote. On the other hand, in the Hymenomycetes the sexual process is more complicated, because it takes place between *multicellular* and *multinucleate* mycelia and results in *the diploidisation of all the growing cells of each mycelium.* It is the non-fusion of nuclei of opposite sex and the establishment of conjugate pairs of nuclei which makes this diploidisation possible.

The development of a haploid hypha (*ab*) or (*AB*), which has just become diploidised owing to the entry into it of nuclei derived from either a haploid mycelium of opposite sex or from a diploid mycelium (*AB*) + (*ab*), is shown in Fig. 7, where it will be seen that, as the cells grow in length or branch, conjugate nuclear division takes place, and that each conjugate nuclear division is accompanied by the formation of a clamp-connexion. When, in a dung-ball, a diploid mycelium of *Coprinus lagopus*, like that shown in Fig. 7, stage 3, meets a haploid mycelium (*AB*) or (*ab*) of the same species (*cf.* Fig. 2) the diploid and the haploid mycelia doubtless fuse hyphally and the diploid mycelium diploidises the haploid mycelium (*cf.* Fig. 6), thus increasing the chances that one or more vigorous diploid fruit-bodies developing all the possible sexual kinds of spores (*AB*), (*ab*), (*Ab*), and (*aB*) will be produced rather than one or more relatively feeble haploid fruit-bodies developing only one of the four possible sexual kinds of spores. There can be no doubt that, in *Coprinus lagopus* and in other similar Hymenomycetes, the diploidisation of haploid mycelia by appropriate diploid mycelia is a distinct aid to reproduction.[4]

In conclusion, the author desires to acknowledge a grant in aid of the work made by the Research Council of Canada and valuable assistance in making the experiments given by Miss Ruth Macrae.

Recent Hydro-Electric Developments in Switzerland.

By Dr. BRYSSON CUNNINGHAM.

FROM the report for 1929 of the Swiss Service des Eaux, it is to be gathered that developments of hydro-electric energy have been prosecuted during recent years with unabated enterprise and zeal. There was merely a slight falling-off during 1929 in the productive capacity of the power stations, due essentially to the intense cold in the early part of the year and to depletion of the water supplies in the autumn. The returns show a total of 4178 million k.w.h. as compared with 4410 million k.w.h. and 4350 million k.w.h. in the two years immediately preceding. The adverse conditions necessitated recourse in a large measure to the supplies of water stored in the lakes, and the deficit was only made good towards the end of the year.

The most important installation put into operation during 1929 was the power station at Handeck, in connexion with the river Aar, an undertaking of the Forces Motrices de l'Oberhasli S.A., Innertkirchen. This has a present capacity of 60,000 horse power, with an ultimate possibility of 120,000 horse power. Among projects still in course of construction at the end of the year may be mentioned an installation on the Dixence in the Canton of Valais, of 175,000 horse power, and another of 50,000 horse power at Monte Piottino in the Canton of Ticino. An installation of 140,000 horse power at Ryburg-Schwörstadt on the Rhine will be partially Swiss.

It is computed that, on Jan. 1 last, the power stations in Switzerland, either in operation or in course of construction, aggregated a total capacity of about 2,700,000 horse power. Some of these stations are of considerable individual capacity, among them being those of Vernayaz (Canton Valais) for the Swiss Federal Railway, 108,000 horse power; Waggital (Zurich), 90,000 horse power; Löntsch (Glarus), 66,000 horse power; and Laufenburg (Rhine), 65,000 horse power.

A recent visit to the Engadine brought me into close proximity with a number of hydro-electric installations which have materialised during the past quarter of a century. The district is particularly rich in sites affording scope for power development and some of these have now been exploited almost to the full extent of their capacity. One of the most striking examples, which I had an opportunity of inspecting, is the undertaking of the Brusio Power Company, which has its headquarters at Poschiavo in the extreme south of the Canton of the Grisons and within a short distance of the Swiss-Italian frontier.

The series of stages by which the Brusio Power Company develops the hydraulic capacity of the southern slopes of the Bernina Range and the Poschiavo Valley commences at the summit level of the Bernina Pass, where there are two sheets of water forming a natural reservoir for impounding purposes at a level of 2200 metres above the sea. The two sheets of water, more or less frozen, of course, during a considerable part of the year, are Lago Bianco (White Lake) and Lago della Scala (the precise signification of which between 'staircase', 'scale', 'succession', and 'landing-place' is not easy to determine). The former is much the larger of the two, but they are so closely adjacent within a common depression as essentially to form

a single basin, which has been adapted so as to provide a supply of 15 million cubic metres of water for power purposes. To this end, the two lakes have been connected and by means of dams at each extremity of the basin the water level has been raised 5·5 metres, bringing the surface up to 2236·16 metres above sea level over an area of 1·36 square kilometres. Under normal working conditions, the water level can be lowered to 2226 metres, which is the state of affairs shown in the photographic view of the basin reproduced as Fig. 1. In order to augment still further the available resources, a set of three pumps has been installed for drawing water from the deeper portion of Lake Bianco, by means of which the level may be reduced to 2210·16 metres above the sea, the maximum difference in level between the fully impounded and the most depleted condition being thus increased to 26 metres.

FIG. 1.—The Bernina Lakes reservoir at the summit level of the Bernina Pass. View looking south. By courtesy of Die Kraftwerke Brusio.

The Bernina Lakes reservoir is fed by an average annual precipitation of 1500 mm. in the catchment basin and by summer seasonal meltings from the Cambrena glacier.

From the snow and ice of the Bernina ridges two main valleys descend towards the south and eventually merge into one another in the Poschiavo plain. One of these, the Val Pila, receives the natural overflow from the two lakes described above and also the discharge from the Palü glacier at the foot of Piz Palü on the ledge overlooking Cavaglia, where it gives rise to the torrent Cavagliasco; the other, the Val Lagoné, receives the flow of the upper Poschiavino, fed in turn by the streams from the Val di Campo. The Poschiavino, united with these tributaries at Robbia, passes through the valley of Poschiavo, having by this time attained an appreciable amplitude of flow, so far as Lake Poschiavo. This is an extensive natural basin lying at a level of 964 metres above the sea and having a superficies of 1·96 square kilometres. It is utilised to the extent of providing 14 million cubic metres of water for a power station below. For this purpose a retaining dam has been constructed across the bed of the Poschiavino at the point of exit from the lake and provided with an intake which is suitable for taking the discharge consequent upon lowering the lake level by 8½ metres. The lake is replenished in due course during the season of melting snow. After leaving the lake at Meschino, the Poschiavino descends 433 metres in a horizontal distance of 5 kilometres to the Swiss-Italian frontier at Campocologno. Beyond this station there is one further stage of development at the junction with the river Adda near Madonna di Tirano.

In all, the series of progressive developments consists of five power stations, situated in sequence at Palü, Cavaglia, Robbia, Campocologno, and Poschiavino. The first of these, which receives its supply direct from the Bernina Lakes and the Palü glacier, has

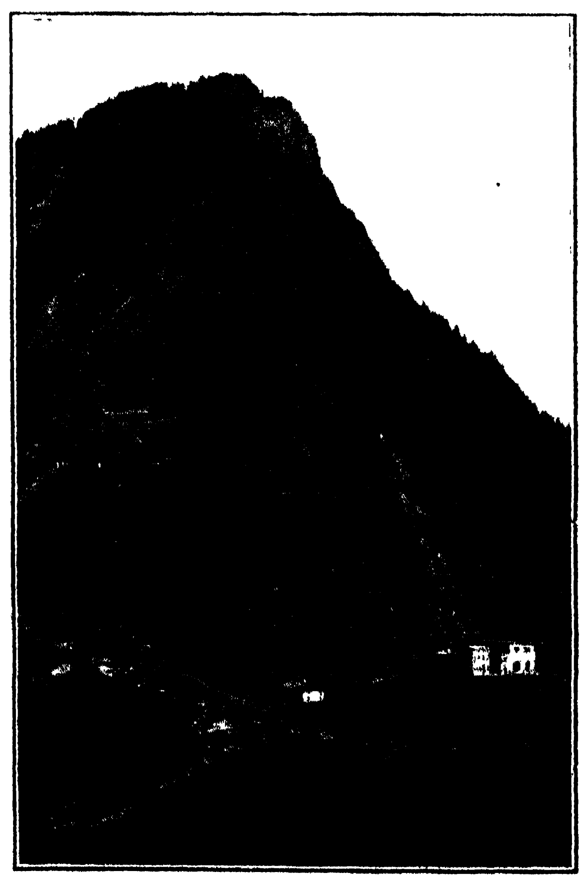

FIG. 2.—Power station at Robbia. By courtesy of Die Kraftwerke Brusio.

a capacity of 15,200 horse power; Cavaglia power station, at a height of 1709 metres above sea level, develops 10,000 horse power; Robbia (Fig. 2), at a height of 1082 metres, develops 16,000 horse power; Campocologno (Fig. 3), at the level of 531 metres, develops 45,000 horse power, making a total within Swiss territory of 86,000 horse power, to which is to be added the 14,000 horse power of the Poschiavino station, bringing the total up to 100,000 horse power.

Nor is this the full tale of possible exploitation. The storage capacity of the Bernina Lakes and of that at the foot of the Palü glacier are susceptible of further artificial developments. The waters of the upper reaches of the Poschiavino in the Val Lagoné and of its influents from the Val di Campo are capable of being brought into use, as well as those of the Cavagliasco, the Bernina, and the Palü.

The record as it stands at present, however, is a most interesting example of the detailed, step-by-step utilisation of the full resources of an Alpine watercourse from its source in the glaciers of the summit to its final absorption in the comparatively low-lying and slow-moving river in the valley below—a descent which amounts to nearly 6000 feet. The conditions, of course, cannot be paralleled in Great Britain, but they are of interest as indicating how vast resources of power in mountainous regions, which for lack of knowledge and need of incitement have been ignored or neglected in the past, are now being brought into effective service. The works in question have been executed during the period of a quarter of a century commencing in 1903, the first installation at Campocologno having materialised in 1906, and the stations at Palü and Cavaglia having been put into operation at the close of 1927. A tribute is due to the initiative and foresight of the progenitors of the undertaking, as well as to the skill and enterprise with which the various sections of the work have been designed and carried out. I must also take the opportunity of expressing my acknowledgments to the Brusio Power Company, and in particular to the director, Herr Rickenbach, for the facilities which were courteously afforded me for inspecting the whole series of stations and for the information and photographs which have been kindly supplied at my request.

The electric current which is generated at the respective stations is transmitted between them by three principal lines of alternating current, three-phase, 23,000 volts, 55,000 volts, and 140,000 volts. The joint supply is transmitted northwards for utilisation in Switzerland by the Bernina Railway, the Rhaetian Railway, and by various local centres in the Engadine and even so far as Zurich; southwards, it is exported into Italy, where it is linked up with the system of the Lombardy Company serving the province of that name.

Had time permitted, it would have been interesting to inspect the series of power stations belonging to the A. G. Bündner Kraftwerke and located in the valley of Prättigau in the Lower Engadine. These have been in operation since 1922–23 and comprise installations of 14,000 horse power at Küblis, of 10,000 horse power at Klosters, and of 7500 horse power at Schlappin. Ultimately, the aggregate of the capacities is to be increased to 55,000 horse power.

Also, alongside the track of the Rhaetian Railway from Bevers to Chur, there is a power station at Thusis at the entrance to the Via Mala Gorge which utilises the water of the Hinter Rhine and develops energy to the extent of 13,500 horse power, which is supplied for the use of the railway system. The Albula station not far distant, of 26,600 horse power, should also be mentioned: it supplies current to the municipality of Zurich, as also does the Heidsee station of 13,000 horse power. Other sites are in course of exploitation.

FIG. 3.—Power station at Campocologno. By courtesy of Die Kraftwerke Brusio.

Sufficient, however, has been enumerated to show that, even on a quite casual and very cursory survey, there is impressive evidence of notable activity in the realisation to the fullest possible extent of the wonderful hydraulic resources of the numerous mountain chains which form the predominant and characteristic feature of the country. That this development has been and is of the greatest economic benefit to the Swiss community cannot be doubted for a moment. Natural hydraulic power is an asset of the highest importance, self-replenishing, and, unlike coal deposits, not subject to exhaustion.

Impressive and inspiring as is the solemn

grandeur of the crests and pinnacles of massive rock and ice which tower to the heavens in stately solitude, great mountain ranges have a further claim to distinction in an age of pressing utilitarian needs. The Alpine panorama with its multitudinous snowfields, glaciers, torrents, lakes, and rivers is no less wonderful as an example of how Nature contrives to compensate a country for its economic deficiencies in one respect by benefits of equivalent value, though of another kind.

Obituary.

DR. LEWIS EVANS.

IN the Lewis Evans Collection of Historic Scientific Instruments is a small jointed rule of ivory, inset with a compass needle, and engraved as a portable sundial. It was a special favourite of Dr. Lewis Evans, whose death occurred on Sept. 25 last, because it bears the inscription, "Registered 1853", which by a happy chance was the year of his birth, on Feb. 15. Twenty years later Francis Galton might well have included the Evans family among those English men of science whose hereditary influences and education he described at the Royal Institution, for at least four generations have achieved scientific distinction. The Rev. Lewis Evans, vicar of Froxfield, 1788–1827, was an accomplished mechanician and astronomer, who ground his own specula, recorded observations, and continued to 1864 the calculations on Ferguson's Astronomical Instrument and Rotula, published in 1817. He had been educated at Merton College, Oxford, was instructor in mathematics at the Royal Academy at Woolwich, and became a fellow of the Royal Society in 1823. He was in the habit of communicating mathematical notes to the *Reading Mercury* under the *nom de plume* of 'Felix Ford' (anagram of Froxfield), some of which are preserved with his lecture MSS. in the Lewis Evans collection. One of his sons, Thomas Simpson Evans, LL.D., became an assistant at Greenwich and, later, mathematical instructor at Woolwich. His grandson, Sir John Evans, K.C.B., for many years treasurer of the Royal Society, attained to special eminence as an antiquary, a branch of study which has been materially extended by both his sons—Arthur, who has also the scientific blue-ribbon of F.R.S., and Lewis, the subject of this notice, who died on Sept. 25. On the distaff side, two ancestors had also achieved similar distinction, namely, John Dickinson, F.R.S., F.S.A., and George Dionysius Ehret, F.R.S., the inimitable flower painter, who was born at Erfurt in 1708, and died at Chelsea in 1770.

Owing to the great demands made upon his time and energy by the needs of a great manufacturing business, Lewis Evans was more than forty years of age before he published his first paper, "On Pocket Sundials", a modest article illustrated by neatly executed cuts of the author's own drawing. This was followed by a fuller contribution upon the same subject to Mrs. Alfred Gatty's standard "Book of Sundials", 1900. His knowledge was largely based upon his own rapidly expanding collection of scientific instruments, in which a perfect Roman portable dial of about A.D. 300 was then one of the greatest treasures. In 1901 there appeared in *Archæologia* the account of another of his discoveries—the original dial of gilt brass made for Cardinal Wolsey by Nicholas Kratzer, who at the time was "reading Astronomy in the University by the command of King Henry VIII. and soon after made by Cardinal Wolsey his Mathematical Reader when he first settled his lecture there". Kratzer was made a fellow of Corpus by Richard Fox in A.D. 1517.

From this time on, many writers at home and abroad drew upon the experience of Dr. Evans, notably Dr. Joseph Drecker of Dorsten, and with the dispersal of other collections his own collection grew. It was many years before he could obtain an astrolabe, but "nothing succeeds like success", and the first he acquired was soon followed by some three score others, the most important of which he figured and described in "Some European and Oriental Astrolabes", in the *Archæological Journal* in 1911. In 1922 he offered the whole of his unique collection of dials and early scientific books and instruments to the University of Oxford: It is by far the most important collection of the kind that has ever been given to a university, and owing to peculiar circumstances, the present gift is a lasting memorial to the noble-minded generosity of the donor: for, like the Mensing collection, it might quite easily have been sold for a fortune to America, and thus have been lost to Europe. Incidentally it has served as a nucleus around which other benefactors, including many Oxford colleges, have deposited instruments and objects of value for illustrating the progress of scientific studies and research in the University. In the past five years the space needed for the proper exhibition of the collection has doubled in area, and apparatus of the very greatest importance has had to be refused, on the ground that the best exhibition space available in the Old Ashmolean Building is still being occupied by the staff and books of the English Dictionary, although that work was completed many months ago.

As was recently pointed out in NATURE in a letter signed by the president of the Institute of Physics and others, scientific instruments, often the landmarks of invention, are lost so long as they are hidden and not in the charge of someone who appreciates their scientific value. No one realised this more vividly than did Dr. Lewis Evans himself. Although an ardent admirer of art and craftsmanship, he felt that to place unique instruments of science among art objects in a gallery of art, as is the case in the British Museum and at South Kensington in London, or at the Ashmolean Museum in Oxford, or to group scientific apparatus among books and to catalogue it as 'manuscripts', as is now the practice in the Bodleian Library, is both derogatory to science and destructive to the proper study of its history. He therefore determined that

his collection should either 'go to the hammer', or else be shown as a scientific collection with all the advantages of exhibition that art collections usually enjoy. By the greatest good fortune, a part of the most historic building connected with the early history of science in Britain, the Old Ashmolean, was available, and this being approved by Dr. Evans, was allocated by the University to his collection. The Goldsmiths' Company voted £1000 for initial expenses, and is now offering £500 more if and when a greatly needed extension of exhibition space is forthcoming either in the Old Chemical Laboratory or in the original meeting-room of the Oxford Scientific Society of 1683. A benefactor to complete the good work which Dr. Lewis Evans has so generously begun is urgently needed, for the losses of most important instruments are great and are continuing. R. T. G.

THE RIGHT HON. EDWARD ALLEN, BARON BROTHERTON OF WAKEFIELD.

THE career of a great industrial leader is not one which demands from him a platform exposition of his aims, policy, and programme as a condition of success, but perhaps all the more on that account any self-revealing utterances from such a man have a peculiar interest and special value. With Lord Brotherton, who died on Oct. 21 at the age of seventy-four years, it so happened that, in the last few months of his long and strenuous life, circumstances combined to break the barriers of constitutional reserve and led him to speak to sympathetic listeners of his experiences and aspirations.

Three occasions, different in character, come to the mind of the present writer. The first of these was the laying of the foundation-stone of the Brotherton Library at the University of Leeds. Lord Brotherton there spoke in firm voice and measured sentences of carefully prepared wording to an audience of the University and its friends. It was a dignified expression of what was in his mind in making this generous monetary gift, which should enable the University to erect a noble building for the housing of its library, and in adding thereto not only the fine collection of books which it had been his pride to bring together in his own home, but also an endowment to secure their care and maintain their usefulness.

On the same evening Lord Brotherton was the guest of the University at a dinner, and there, speaking with feeling and in simple, direct, and unprepared language, it was evident that he had the greatest possible wish to escape from his habitual reserve, and to get into closer human contact with the members of the Senate and others whose academic life and outlook were necessarily so different in some respects from his own. The sincerity and unconventionality of this speech were remarkably impressive.

On the third occasion, a little later, Lord Brotherton was in the midst of his fellow-members of the Society of Chemical Industry, who had marked their appreciation of his high standing and achievements as a master of their calling by conferring upon him the Messel medal and inviting him to deliver the Messel lecture at the annual meeting of the Society in Birmingham. He expressed at once his intention of dealing with what he knew best, and told the story of his own connexion with industrial chemistry. He told how he left Owens College to engage, in the first place, in the manufacture of ammonium sulphate, and showed how he was able to extend his operations in various directions, mainly by organisation, insight into the opportunities presented by the introduction of new chemical processes, and the determination to place his resources boldly at the back of any venture which had won his confidence. So came into being and good fortune the firm which bore his name, and so later arose his connexion with the Cassel Cyanide Company, of which he became chairman in succession to Sir George Beilby.

These three occasions of self-explanation came close in time to the termination of a career marked in equal measure by outstanding achievement and the exercise of a large-minded generosity.

J. W. COBB.

DR. E. H. WILSON.

THE death of Dr. Ernest Henry Wilson on Oct. 15, as the result of a motoring accident, will be lamented in botanical and horticultural circles, not only in Britain and America, but also throughout the world, for Wilson's activities were truly international. The news to hand from the Arnold Arboretum states that Mr. and Mrs. Wilson were returning from a visit to their daughter and her husband, Mr. and Mrs. G. L. Slate, at Geneva, New York State, when their car skidded on the greasy surface while travelling on the Boston Road, Worcester, Mass., crashing through a fence and down a 40-feet embankment. Mrs. Wilson was killed outright, and Dr. Wilson died soon after admission to hospital.

Wilson was born at Chipping Campden, Gloucestershire, on Feb. 15, 1876. He entered the Birmingham Botanic Gardens as a student in 1892 and moved to Kew in January 1897. In the lecture room and in the practical work of the Gardens it is evident that Wilson soon attracted attention, as he obtained first place in several of the lecture courses, and was awarded the Hooker Prize of the Mutual Improvement Society for an essay on Coniferæ. Wilson's next move was to the Royal College of Science, South Kensington, where he obtained a studentship with a view to becoming a teacher in botany.

At this time, the late Dr. Augustine Henry was sending home specimens—a few seeds, and letters descriptive of the floral wealth of Hupeh, China. Messrs. Veitch, of Chelsea, decided to send out a collector, and asked the then Director of Kew, Sir William Thiselton-Dyer, to recommend a suit-

able man. Wilson was chosen, and made his first journey between 1899 and 1902. This proved so successful that a second journey was made during 1903-5. Two further trips followed in 1907-9 and 1910-11, these journeys being on behalf of Harvard University and a few subscribers. The results of his labours are recorded in "Plantæ Wilsonianæ", which contains descriptions of 3356 species and varieties. Of these, nearly nine hundred were new, including several new genera. In 1914 and 1917 Wilson made two journeys to Japan. He was appointed Assistant-Director of the Arnold Arboretum in 1919. The next year he set out on a two years' tour through Australia, New Zealand, India, and Central and South Africa. On the death of Prof. C. S. Sargent in 1927, Wilson was appointed Keeper of the Arnold Arboretum.

An untiring worker, Dr. Wilson found time to write nearly a dozen books on his plant collections and studies. The best known of these are: "A Naturalist in Western China", 1913; "Cherries of Japan", 1916; "Conifers and Taxads of Japan", 1916; "Lilies of Eastern Asia", 1925; and "Aristocrats of the Garden", 1926. His work received recognition from numerous learned societies, including the Victoria medal of the Royal Horticultural Society in 1912, the Geoffrey St. Hilaire gold medal, the George Robert White medal, the Veitch memorial medal, and the Rhododendron Society's cup. He was a fellow of the American Academy of Arts and Sciences, an honorary M.A. of Harvard University, and in June last Trinity College, Hartford, Conn., conferred on him the degree of D.Sc.

As a plant collector, botanist, horticulturist, and author, Dr. Wilson possessed great knowledge of his subjects. He was also himself a very likeable man, which makes his loss the greater. A. O.

PROF. FLORIAN CAJORI.

WE much regret to record the death, which occurred on Aug. 14, of Prof. Florian Cajori, professor of the history of mathematics in the University of California. An appreciation of his work by Prof. David Eugene Smith appears in *Science* of Sept. 19, to which we are indebted for the following particulars. Florian Cajori was born in Switzerland on Feb. 28, 1859, and went to the United States when he was sixteen years of age. Between 1889 and 1918 he was at Colorado College, first as professor of physics, later as professor of mathematics, and finally as dean of the Department of Engineering. Throughout this period he paid particular attention to the history of his subjects. In 1918 he went to the University of California as professor of the history of mathematics. Cajori was the author of several works on the history of the physical sciences and mathematics, and at the time of his death was engaged on an edition of Newton's "Principia". His most important work was "The History of Mathematical Notations" (2 vols., 1928, 1929); while his "History of the Logarithmic Slide Rule" (1909) is still one of the most authoritative treatises on the subject.

WE regret to announce the following deaths:

M. Paul Appell, president in 1914 of the Paris Academy of Sciences, and more recently Rector of the University of Paris, who was distinguished for his mathematical work, on Oct. 23, aged seventy-five years.

Dr. W. R. Eckardt, director of the Meteorological Observatory at Essen, and author of "Grundzüge einer Physioklimatologie der Festländer", aged fifty-one years.

Dr. W. M. W. Haffkine, C.I.E., formerly bacteriologist with the Government of India, distinguished for his research work on plague and cholera, on Oct 26, aged seventy years.

News and Views.

No one more appropriate than Mr. H. G. Wells could have been found to introduce Prof. L. T. Hogben to his audience on Thursday, Oct. 23, when he read himself in as professor of social biology at the London School of Economics. Mr. Wells hailed the new experiment in bringing biology and economics together as the portent of a complete change of direction and method for the social and economic sciences, and spoke of it as a most exciting event. He did not spare the traditional treatment of the dismal science, which, dealing with human things, was, he said, entirely inhuman. While pretending to be a science, it began with hypotheses and definitions in the mediæval manner, and maintained to the present time the flavour of scholasticism. It would not have been Mr. Wells if he had not clearly been rejoicing in the belief that the new chair would be revolutionary: with the rapid advances in the knowledge of the biology of man made in the last quarter of a century, the new body of knowledge which can be brought to bear on sociology and economics will bring them within the region of pure scientific treatment. He defined the scope of Prof. Hogben's work as the treatment of one special case of the science of ecology, the science of the balance and welfare of species the study of the fluctuations of the human species under the fluctuating pressure of circumstances. Mr. Wells paid the London School of Economics the compliment of finding the establishment of research into this new byway of science only what one would expect of it, and he described the new professor as a most hopeful and desirable adventurer.

PROF. HOGBEN'S address, a synopsis of which appears elsewhere in this issue, did nothing to damp the liveliness of Mr. Wells's hopes and anticipations. It was a brilliant example of the exposition of a difficult scientific thesis in terms of smooth prose enriched by a wealth of humour and literary allusion. Prof. Hogben is not overwhelmed by the scope or the difficulty of the adventure on which he has embarked. Although Mr. Wells suggested that he was about to cut the first furrow in an almost virgin soil, it is plain enough that the territory has already been surveyed, and that it will not be a random

direction that this furrow will take. Nevertheless, Prof. Hogben sounded warning notes. He pointed out that the outlook which evolutionary biology brings to the study of human society is neither a philosophy of social reform nor a philosophy of social reaction but a philosophy of social discovery. Above all, he drove home the need for discipline, restraint, and detachment in the discussion of the genetical foundations of racial and occupational stratifications in human society. To force the issues into the political arena at the present stage of inquiry would be to render these virtues impossible to exercise. In conclusion, Prof. Hogben, changing the metaphor, begged that an astronomical estimate should be taken of the time required for the seed now being sown to germinate. Accepting the conclusions of Sir James Jeans, the School of Economics has five million million years of life in which to cherish and tend it. Prof. Hogben indicated that he confidently relied upon the School, with its tradition of free inquiry, to extend the necessary care and sympathy in its early, tender stages.

Sir David Prain's Alexander Pedler Lecture, delivered in the University of Liverpool on Oct. 22, under the auspices of the British Science Guild and the University, explored the troublesome problem of the academic attitude towards applied science. The term science discipline, which was Huxley's description of the methods of obtaining natural knowledge contrasted with technical exercise in the employment of natural knowledge, opened the door for a review of Huxley's ideas concerning the place of science in the universities, side by side with an historical account of the changing mutual relationships of the arts and the sciences since the fourteenth century. Sir David Prain had no difficulty in showing that in Huxley's mind the purpose of science discipline was twofold: to furnish those who wished to serve the community scientifically with the kind of natural knowledge that would prepare them for technical training, as well as to render all scholars in any ideal university competent to appreciate the scientific help afforded the community by those specially trained to give it. To orientate the first of these purposes falsely, while wholly ignoring the second, is to accentuate the antithesis held to exist between 'pure' and 'applied' science, and leads to the neglect by those entrusted with university organisation of the 'patient study' of the special features of science discipline for culture and science discipline for training that Huxley clearly envisaged. The idea that an advance in natural knowledge, however slight, is of greater consequence than any application of natural knowledge, however important, arises from an unreal distinction between 'pure' and 'applied' science. Teachers of natural history in the eighteenth century used system, and teachers of philosophy in the sixteenth century used controversy, as ends in themselves, with well-known consequences. Twentieth century teachers of science, said Sir David Prain, have to guard themselves against a like misuse of discovery.

Huxley's views concerning the place of science in universities were comprehensive. Science implanted in the misnamed 'Arts' faculty was to lead men to an understanding of all the methods of obtaining knowledge. Acquisition was incidental, but inevitable and extensive. The science faculties were to be intensive, supplementary to arts, and preparatory to training, but nevertheless cultural as a matter of necessity. It is a curious reflection on the antagonisms that praise of the useful engenders that art (in the unequivocal singular) has survived similar trials. Surely no artist now ever worries his head about 'art for art's sake', not because he has comprehended this once provocative assertion or disposed of it, but because it has ceased to stand for anything real. A quarter of a century later, science for science's sake still has power to wound. Science for the sake of its supreme intellectual interest is not something that leads to the contrasting of "second-rate advancement with first-rate application". Active and powerful minds are not usually undiscriminating. They imply, as a rule, powerful motives. Science for the sake of its impressive material consequences is none the less science. Another reflection concerning the place rather than the matter of Sir David Prain's stimulating address, is that the University of Liverpool is now the only 'scientific body' in Liverpool that could invite an Alexander Pedler lecturer in accordance with the conditions of the foundation. The courtesy of the University is warmly appreciated by those concerned in arranging the lecture; but it may be remarked, for the encouragement of creative culture in Liverpool, that the learned societies that still flourish in some Scottish and provincial centres have not only a great and honourable past but also a respectable present and a worthy future. Reference books give the Royal Institution of Liverpool a theatre, a library, a lecture-room, a museum, a room for the use of scientific instruments, and even a laboratory. The functions that these amenities suggest should be restored to it.

The centenary celebrations of the Royal Geographical Society began on Oct. 21, when the Duke of York, representing the King, who is the Society's patron, formally opened the new lecture theatre and the library and other buildings which have been added to the Society's house at Lowther Lodge, Kensington Gore. In declaring the building open, the Duke of York mentioned that the Society is the third of the great geographical societies of the world to celebrate its centenary, having been preceded only by the Société de Géographie de Paris in 1921 and the Gesellschaft für Erdkunde of Berlin in 1928. The new lecture hall has seating accommodation for at least 860 and its acoustics are admirable. A wide ambulatory connects the old building with the new, and its circuit gives ample space for movement and conversation after evening meetings. The library and map collections now have considerably increased space. Addresses of congratulation were presented by delegates representing many geographical societies throughout the world and kindred societies in Great Britain. Several of the visiting delegates were made honorary members of the Society.

On the evening of the opening day of the celebrations, addresses on the history of the Royal Geograph-

ical Society were delivered by Sir Charles Close (president), Dr. H. R. Mill, Mr. D. Freshfield, Sir Francis Younghusband, and the Marquess of Zetland. On the following day there began a series of papers on the habitable globe. Dr. A. Penck refuted the theory that within historic times there has been any considerable or progressive change of climate in Central Asia, and Prof. J. W. Gregory outlined the evidence against any change of climate in Palestine within the same period. Mr. L. B. S. Leakey, in speaking of East Africa, stated that the suitability of conditions in that country for permanent white settlement have yet to be proved, but he believes that they are probably favourable. This series of papers was continued on the next day by Prof. A. M. Carr-Saunders and others, and several short papers on striking episodes in recent explorations were given by various travellers. Other events in the celebrations included a reception of delegates and fellows in the Society's house on Oct. 22 and a centenary dinner on Oct. 23, at which the Prince of Wales presided.

THE centenary of the birth of John Whitaker Hulke, eminent as a surgeon and a geologist, occurs on Nov. 6. In his day he was president of the Geological Society of London (1882-84) and president of the Royal College of Surgeons (1893-95) an unusual association of scientific activities. Born at Deal, the son of a medical practitioner in the town, he was educated in Germany and at King's College School. He rendered medical service in the Crimean War, becoming afterwards surgeon to Middlesex Hospital, where, apart from geology, most of his life's work was accomplished. In 1859 his well-known essay, "Diseases of the Retina", was awarded the Jacksonian prize of his college. It was followed by a treatise on the ophthalmoscope, an instrument in use in Germany but at the time unfamiliar amongst English practitioners. He edited (with J. Burdon Sanderson) the collected papers of Sir William Bowman. Hulke was elected into the fellowship of the Royal Society in 1867, his claim being based exclusively on researches relating to the anatomy and physiology of the retina in man and the lower animals, particularly the reptiles. His knowledge of comparative anatomy, and especially of osteology, enabled him rapidly to grasp the meaning of structures presented by the remains of fossil vertebrates. It is said that he found relaxation from professional anxieties by working with his own facile chisel on the freeing of fossils from their matrices. Hulke was a faithful servant of the Geological Society, occupying not only the presidential chair, but also filling the posts of secretary and foreign secretary. He died in London, on Feb. 19, 1895.

THE Freshwater Biological Association, the principal object of which is to secure the establishment of a freshwater research station to investigate the numerous outstanding problems of freshwater biology, has secured the support of the leading scientific societies and of a large proportion of the bodies interested in water pollution, freshwater fisheries, and the like. The conference convened by the Council of the Association at Fishmongers' Hall on Feb. 21 last (see NATURE, Feb. 15, p. 241) afforded striking evidence of the interest displayed, and showed that there was a real and widely felt need for such a station. Promises of financial support in the form of annual grants have been received from many sources, but they are conditional upon the actual founding of the station as a research centre. The Council is therefore making an appeal for contributions towards a fund for the establishment and initial equipment of the station, and several hundred pounds have already been subscribed. To make a satisfactory beginning a sum of between three and four thousand pounds is, however, required. The Council is appealing especially to those interested in freshwater, such as public bodies responsible for water supply, medical officers of health, water and sanitary engineers, fishermen, and naturalists, who should realise the importance of the projected station in relation to the conservation and development of freshwaters and their amenities on an economic and scientific basis. Contributions should be sent to the treasurer of the Association, Mr. D. J. Scourfield, 6 Chadwick Road, Leytonstone. The chairman of the Council of the Association is Prof. F. E. Fritsch, and Mr. F. Balfour-Browne, Winscombe Court, Winscombe, Somerset, is acting secretary.

IN an address to the Liverpool Centre of the Institution of Electrical Engineers, delivered on Oct. 20, Mr. A. J. Pratt gave interesting statistics illustrating the very rapid growth of telephony. The first actual talking instrument was constructed in 1875, and on Mar. 7, 1876, the famous Bell patent was issued. In 1929 the Bell System of the American Telephone and Telegraph Co. controlled ninety million lines, with a total of about sixty-five million calls a day. If we count companies in the United States, we find that the Bell Telephone Co. is only one in ten thousand. Some of these companies, however, are very small. A universal linkage of all the telephones in the world by the aid of radio transmission is in process of realisation. It is impossible to separate the local exchange from the long-distance telephone system, as each is mutually dependent on the other. In Great Britain an immense programme of building and exchange plant reconstruction has been worked out since the War. There are now nearly 5000 exchanges, more than 300 of which are automatic. When the business man, following the American custom, needs a telephone not only in his office but also in his sitting-room and bedroom, the present rate of growth of telephony will rival that of radio broadcasting in Britain, which in the short space of seven years has attracted more than three million licensed listeners. Post Office officials consider it very desirable that the telephone habit be cultivated. It is suggested that this can be done by a wider application of the use of the internal extension telephone.

THE presidential address delivered at Newcastle on Oct. 24 by Mr. J. McGovern to the North-East Coast Institution of Engineers and Shipbuilders was devoted to a brief review of modern shipbuilding. Referring to the position of the north-east coast of Britain in the shipbuilding and engineering industry, Mr. McGovern

said that in 1929, 750,000 tons of ships were launched in the district, while the machinery completed had an aggregate of 682,000 horse power. Great Britain is now building 45 per cent of the world's tonnage, as compared with 57 per cent in pre-War years. Recent progress in naval architecture is one of steady research rather that of epoch-making development; but it cannot yet be claimed that experimental technique has reached a stage where we can be wholly satisfied with the results obtainable. The correlation of model tests with actual service results is rendered difficult by the insufficient precision with which powers obtained at sea can be measured. The chief uncertainties arising from attempts to correlate model and ship appear to lie in the assessment of a frictional value for the ship's hull surface, the effect of ship propeller roughness, the probability of some 'scale' effect in extending model results to the ship's actual size, and the comparison between screw performances in the open and in the varying flow obtaining at the stern of varying forms of vessels. Discussing the question of oil engines and steam engines, Mr. McGovern said that the investigations now proceeding may result in giving a new lease of life to steam as a prime mover. There would appear to be considerable economies obtainable by the use of high-pressure superheated steam plants, while the results already achieved in the ships of the Canadian Pacific Steamship Company are unequalled by other prime movers. In other directions, research is also being applied to the determination of strains and the subject of vibration in ships.

SIR ROBERT ROBERTSON, the Government Chemist, reporting on the work of the Government Laboratory for the year ending Mar. 31, 1930, gives a detailed survey of the many activities, interests, and responsibilities of his department. A comparison with last year's report shows that there has been a substantial increase in the number of samples examined, now well above the half-million mark, the rate of increase also having risen considerably. The chemical staff has increased from eighty to eighty-two; the long list of 'other activities' of the members of the staff again demonstrates the important part taken by the Laboratory in the promotion and application of chemical science. References to the absence of any standard for the percentage of fat in cream and to the absence of regulations relating to the marking of skimmed or partially skimmed milk cheese are repeated, and the presence of 2·5 per cent of proof spirit in samples of 'non-alcoholic' beverages is again reported. The number of samples of sea water examined for the Admiralty, the Ministry of Agriculture and Fisheries, and the Fishery Board for Scotland shows a substantial increase; this work is, of course, of noteworthy value in oceanography, since systematic determinations of salinity contribute to our knowledge concerning the drift of water between seas of differing saline contents. Further study has also been made of the diurnal variation in the quantity of dissolved oxygen in rivers; this variation is traceable in some rivers throughout the year. Atmospheric pollution also has been a subject of experimental investigation; a standard apparatus and method for determining the acidity of the air are now being tested at several stations. It appears that free sulphuric acid is present in a proportion which does not exceed a small fraction of the total sulphurous acidity, and that neutral sulphates are also present in small quantities.

UNDER the Food and Drugs (Adulteration) Act, 1928, the Government Laboratory was called upon to report to the Justices on nineteen samples, with the result that in four cases the results were in disagreement with those put forward by the prosecution. All four cases were concerned with milk or butter. Two samples of tinned vegetables examined for the Ministry of Health contained copper, whilst four contained hydrogen peroxide. Six samples of lead pipe carrying a municipal water supply were found to contain deposits of two kinds, one consisting mainly of basic lead sulphate and the other of basic lead carbonate. Deficiencies in condensed milk were found, but most of the adverse reports were concerned with the labelling. All consignments of tea which are imported into Great Britain are subjected to examination, officers of Customs and Excise being trained, for the purpose of preliminary examination, in the Laboratory. Of about thirty thousand samples, 256 contained foreign substances and 217 were unfit for human consumption. Of 1546 samples of beer, 32 contained arsenic in slight excess of the limit laid down by the Royal Commission on Arsenical Poisoning, but in no case (of 85 examined) was saccharin detected. A sample of soap alleged to be made wholly from waste potatoes consisted of ordinary soap loaded with sodium carbonate and starch; whilst two samples of meat meal were adulterated with potato and with mineral matter respectively. As the result of further examination of lime sulphur insecticides, it has been possible to work out the relationships between the various suggested criteria of strength of these products. During the year more than 200 milligrams of high-grade radium salt have been recovered from decayed luminous paint.

THE sphere of work of the League of Nations' Committee on Intellectual Co-operation has recently formed the subject of a general inquiry by a committee specially constituted for the purpose at Geneva. In the light of this committee's report, a number of proposals have been submitted to and approved by the Assembly of the League with the object of defining a programme and improving work in this field. Among the changes thus brought about is the constitution of committees of experts which will replace the formerly existing sub-committees of the League's International Committee on Intellectual Co-operation. An inquiry is to be initiated forthwith into the intellectual life of our time with special reference to methods of education at all stages in the different countries. The attention of governments is being directed to the utility of the work done by the bureaux responsible in the different countries for international interchanges of publications, with the suggestion that they should "be placed in a position to act as liaison between learned societies for exchanges of their publications and should

accordingly be provided with the necessary funds". The work of the International Educational Cinematographic Institute, including the publication in five languages of the *International Review of Educational Cinematography*, is highly appreciated by the Assembly of the League; and governments are being asked to give their sympathetic consideration to the draft convention, prepared and circulated by the Institute, for the abolition of customs barriers which interfere with the distribution of educational films, and generally to lend their aid and support to the Institute.

MANY generous donors have contributed to make the collection of birds in the Hull Municipal Museum fairly representative of the avifauna of the British Isles. The addition of many specimens and the rearranging of the birds of prey, the waders, and the game birds have made necessary the publication of a new "Guide to the Birds" by Mr. T. Sheppard. In it the collection is catalogued, with records of localities, a short comment on the status of each species, and two dozen illustrations of typical examples of the style of mounting adopted. Perhaps it is desirable from the public point of view to keep the nomenclature as simple as possible, and doubtless on this account no racial forms are indicated. But for the study of bird migration or for scientific identification, more than the Linnean binomial is required—and, indeed, the simple method may be misleading. For example, it is obvious that the specimens of golden plover (case 209), described as generally distributed throughout the British Islands, do not belong to the British race at all. The Guide contains many interesting Yorkshire records, and it is unfortunate that the cases should sometimes contain incongruous species (crested tit and abnormal skylark) and sometimes associate British with foreign species which have no British claims (red grouse and willow grouse).

AMONG the recent acquisitions of the British Museum (Natural History) are the following: The Trustees of the Rowland Ward Bequest have presented a fine mounted female specimen of a black howling monkey (*Alouatta niger*). The female is not, as the name of the species implies, black in colour, but a mixture of grey and yellow. A plaster cast of the bust of a young gorilla (John Daniel I.) and a cast of the entire left foot and ankle have been presented by Mr. F. O. Barlow and will shortly be placed on exhibition in the Upper Mammal Gallery. The Government of Greenland recently presented to the Museum a Greenland narwhal. The specimen, which is a male, 10 feet 3 inches in length, with a tusk 14½ inches long, was sent from Greenland packed in salt and arrived at the Museum in excellent condition. A plaster cast of the animal has been prepared and will be exhibited when the new Whale Room, now under construction, has been completed. Among the recent acquisitions in the Department of Geology are three interesting fossils—a fish and two palms—from the Middle Eocene beds of Bolca, near Verona. The fish is a fine example of a rare extinct genus, *Urosphen*, related to the living flute-mouths. The palms, which are both on slabs about six feet in length, are almost complete specimens of small fan-palms. The Department of Botany has received a collection of 101 seaweeds from Sir J. Ross's voyage of the *Erebus* and *Terror* to the Antarctic (1839–43), presented by Miss Jessie Lefroy. The Department already has the flowering plants of the expedition, to which Dr. (afterwards Sir) J. D. Hooker was naturalist. Many cryptogams were received from 1845 to 1854, and a further set was bequeathed, together with his Arctic collection, by Dr. R. M'Cormick, surgeon to the expedition, in 1890. The collection now added is valuable in extending the series and has an additional interest in that it was originally presented to Lady Franklin.

SIR ROBERT HADFIELD recently delivered an address, on the occasion of a luncheon of the Oil Industries Club, in which, after giving a general survey of the importance of the steel industry, that of gold being taken as a standard of comparison, he discussed the question of steels for use in the oil industry. For the purpose of rock drills no alloy steel has proved to be superior to plain carbon steel in cutting quality. The carbon is usually in the neighbourhood of 0·75 per cent, but when special care is taken to keep down the proportions of sulphur and phosphorus, the carbon may be raised to 0·85 per cent. Carbon steels are, however, deficient in toughness, so that small quantities of an alloying element, such as 0·2 per cent of vanadium or 0·6 per cent of chromium, may be added with advantage. Great care in heat treatment is essential, as surface imperfections give rise to fatigue cracks. For the fish-tail bits used in rotary drilling, and for core barrel cutter heads, excellent results have been obtained with an intermediate manganese steel, comparatively low in carbon, but containing 1·5-1·75 per cent of manganese. Such steel, when quenched, has a Brinell hardness of 550-575, and exhibits great toughness. The oil industry has also made demands on the steel-maker for heat-resisting steels in connexion with operations at high temperatures.

AN illustrated description of the construction of the large reinforced concrete tube for vehicular traffic which has been laid in the bottom of the estuary which separates the cities of Oakland and Alameda, on the shores of the Bay of San Francisco, is given in *Engineering* for Sept. 26 and Oct. 10. Owing to the geological formation, the driving of a tunnel beneath the estuary was impracticable and the unusual plan had been adopted of building a great part of the tube in lengths in a dry-dock and then sinking them into position after they had been floated. The total length of the structure is 4336 ft., and this includes 12 tubular sections each 203 ft. long, which were built in the dock. These sections have an external diameter of 37 ft. and are 2 ft. 6 in. thick, the concrete being heavily reinforced both circumferentially and longitudinally. Internally, the tube is divided into three sections by a ceiling and a roadway, the space above the ceiling being used as an exhaust duct and that under the roadway as a fresh-air duct. As completed each section weighed about 5000 tons, and as some of the sections were slightly curved, great care had to be

taken with their alignment. All the sections were, however, successfully sunk into position and then neighbouring sections were joined together by circumferential belts of Tremie concrete. The entrance portals are of a striking character and in them are housed the ventilation plants. The tube has a capacity of 4224 vehicles per hour when they are proceeding at 20 miles per hour; while the ventilation is such that it allows for but 4 parts of carbon monoxide in 10,000 parts of air. This remarkable engineering structure is called the Geo. A. Posey tube, after its designer.

THE second Henry Herbert Wills Memorial Lecture in physics was delivered in the H. H. Wills Physical Laboratory, Bristol, on Saturday, Oct. 25, by Prof. J. Franck, of Göttingen. The title of the lecture was "The Relation between Spectroscopy and Chemistry". Prof. Franck outlined a number of methods of determining the heats of dissociation of molecules from their molecular spectra, and showed how it is possible by spectroscopic methods to classify various types of chemical binding. He also indicated methods of deducing another thermochemical constant, namely, the heat of activation, and gave a qualitative physical picture of the function of a catalyst in promoting homogeneous chemical reactions. The lecture was well attended, and the audience included a number of visitors from other universities.

THE second of a series of exhibitions, at the galleries of the Royal Photographic Society, to illustrate the application of photography to the various branches of science, art, and industry, is to be devoted to "Photography in Astronomy". The striking results which have been secured by the combination of the photographic plate and the spectroscope will be well exemplified, and photographs of star fields, nebulæ, and other objects, many of which have been revealed by photography, will be on view. There will also be illustrations of instruments, telescopes, cameras, used in the different branches of astronomical research. The exhibition will be open daily at the Society's house, 35 Russell Square, London, W.C.1, on Nov. 3–29 (Sundays excepted), from 10 A.M. to 5 P.M. There will be no charge for admission. Lectures will be given during the exhibition—by Prof. F. J. M. Stratton, on Nov. 3, on "Solar Eclipse Photography"; by Prof. Herbert Dingle, on Nov. 17, on "Spectrum Photography"; and by Mr. J. H. Reynolds, on Nov. 24, on the slides and films in the exhibition.

DR. HENRY FAIRFIELD OSBORN, president of the American Museum of Natural History, has been awarded the Daniel Giraud Elliot Medal for 1929 by the U.S. National Academy of Sciences for his recent monograph on Titanotheres.

THE sixth annual Norman Lockyer Lecture of the British Science Guild will be given by Sir William Pope in the Goldsmiths' Hall, Foster Lane, E.C. (by permission of the Goldsmiths' Company), on Thursday Nov. 13, at 4.30 P.M. The subject of the lecture will be "Science and Modern Industry". Sir Samuel Hoare, president of the Guild, will take the chair. There will be no charge for admission to the lecture, tickets for which can be obtained from the British Science Guild, 6 John Street, Adelphi, London, W.C.2.

HIS GRACE THE ARCHBISHOP OF YORK will deliver an address on "The Relations between Philosophy and Religion", at University College, Gower Street, W.C.1, on Tuesday, Nov. 18, at 8.15 P.M. The chair will be taken by Sir Oliver Lodge. Tickets for this meeting, which is one of a series arranged by the British Institute of Philosophical Studies, can be obtained, without charge, from the Director of Studies, University Hall, 14 Gordon Square, London, W.C.1.

AT the annual statutory meeting of the Royal Society of Edinburgh, held on Oct. 27, the following Council was elected: *President*, Sir E. A. Sharpey-Schafer; *Vice-Presidents*, Prof. J. Graham Kerr, Prof. W. Wright Smith, Prof. F. G. Baily, Prof. T. J. Jehu, Prof. J. H. Ashworth, Dr. A. Logan Turner; *General Secretary*, Prof. R. A. Sampson; *Secretaries to Ordinary Meetings*, Prof. C. G. Darwin and Prof. James Ritchie; *Treasurer*, Dr. James Watt; *Curator of Library and Museum*, Prof. D'Arcy W. Thompson; *Councillors*, Dr. J. B. Clark, Prof. F. A. E. Crew, Prof. J. Montagu F. Drummond, Mr. D. A. Stevenson, Prof. H. W. Turnbull, Sir James Walker, Dr. James Drever, Mr. A. H. R. Goldie, Dr. R. A. Houstoun, the Hon. Lord Sands, Mr. Murray Macgregor, and Dr. A. Crichton Mitchell.

AT the Imperial Botanical Conference held on Aug. 15 at the Imperial College of Science and Technology, South Kensington, the following resolution was carried unanimously: "That an Imperial Botanical Conference take place in England in 1935, shortly before the International Botanical Congress which is to be held in that year in Holland." The following interim committee was appointed: The Director of Kew (convener); the Keeper of Botany, Natural History Museum; the professors of botany at Oxford and Cambridge; a professor of botany of the University of London (to be nominated by the chairman of the Board of Studies of the University); one representative of the Colonial Office, and one representative of the Dominion Office. It was further resolved that this Committee summon a meeting of British botanists in the near future for the purpose of appointing an executive committee for the said Conference.

THE first number of a new journal called the *Students' Quarterly Journal* has been published by the Institution of Electrical Engineers. Its object is to record the work done by the students' sections of this Institution and to publish short papers by them dealing with technical subjects of general interest. This number is notable, as it gives an abstract of a most interesting lecture on the ship-to-shore radiophone service by Sir Thomas Purves, Engineer-in-Chief to the Post Office.

WE have received Vol. 8 (1929) of the *Transactions* of the Institution of Chemical Engineers, which contains several papers of considerable interest. These

deal with the reactivity of coke, fatigue in metals, acid-resisting steel plant (in which precise directions for oxy-acetylene welding are given), the recovery of benzole from coal gas by adsorption, the absorption of nitrous gases, the fractional adsorption of gases, the industrial applications of active carbon, the evaporation of water in open pans, etc. The volume is fully illustrated and contains numerous tables, and is a production of very high standard.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned: An assistant director of the Research Laboratory of Queen Charlotte's Maternity Hospital—The Secretary, Queen Charlotte's Maternity Hospital, Marylebone Road, N.W.1 (Nov. 3). A graduate assistant in the Junior Technical School of the Wigan and District Mining and Technical College—The Principal, Wigan and District Mining and Technical College, Wigan (Nov. 5). An assistant lecturer in physics in the University of Sheffield—The Registrar, University, Sheffield (Nov. 8). A woman inspector for work in connexion with the agricultural education (including rural domestic economy) of girls and women—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1 (Nov. 10). An assistant lecturer in education in the University of Leeds—The Registrar, University, Leeds (Nov. 10). A student assistant in the Department of Economics at the Harper Adams Agricultural College—The Advisory Economist, Harper Adams Agricultural College, Newport, Salop (Nov. 10). Two scientific assistants and two technical assistants at the Radio Research Station, Slough—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (Nov. 11). Inspectors of plants and produce in the Agricultural Department of the Gold Coast—The Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, Whitehall, S.W.1 (Nov. 17). A plant physiologist in the Department of Agriculture and Horticulture of the University of Bristol, Long Ashton—The Secretary, University, Bristol (Nov. 17). A lecturer in zoology at Armstrong College—The Registrar, Armstrong College, Newcastle-upon-Tyne (Dec. 1). An inspector for Scotland under the Alkali, etc., Works Acts, and inspector under the Rivers Pollution Prevention Act—The Secretary, Department of Health for Scotland, 125 George Street, Edinburgh.

Our Astronomical Column.

Total Solar Eclipse of Oct. 21. The only available station in the eclipse of Oct. 21 was the tiny island of Niuafo'ou, about midway between Samoa and Fiji. It has the drawbacks that landing is difficult and that the island is subject to volcanic disturbances, a considerable eruption having occurred last year. However, as the sun was high, and totality lasted more than 1½ minutes, it was felt that the opportunity should not be missed, and expeditions proceeded to the island from the Dominion Observatory, New Zealand, and from the United States. The former was in charge of Dr. Adams, the Dominion Astronomer; the following particulars, which he transmitted by wireless, are quoted from the *Times* of Oct. 23:—"There were no clouds and the sky was fair during the eclipse. The photographs taken were satisfactory. There was a faint corona with two long streamers, there were six medium prominences, and Bailey's beads were seen. The whole of the proposed programme was carried out."

Particulars about the American party were announced in a *Daily Science Bulletin* (Oct. 9) issued by Science Service, Washington, D.C. It was sponsored by the U.S. Naval Observatory, and was in charge of Dr. S. A. Mitchell, director of the Leander McCormick Observatory; it was his eighth expedition to a total eclipse; the only failure among the eight was the English eclipse of 1927. At the recent eclipse (1930) he proposed to study the flash spectrum. The largest instrument brought from America was a coronagraph of 63 feet focal length, operated by Dr. Ross W. Marriott, of the Sproul Observatory, and Dr. Weld Arnold. This was to be used both for coronal photographs and for obtaining star positions for the measurement of the Einstein deflection of light. No details of the results obtained by the American party are yet to hand.

The next total solar eclipse is that of Aug. 31, 1932, total near Montreal and in the north-east corner of the United States. It is likely to be observed by a great number of astronomers, as the meeting of the International Astronomical Union is to be held in the United States just after the eclipse.

Reproduction of an Old Crayon Drawing of the Moon.—There is in the Radcliffe Observatory at Oxford a large crayon drawing of the moon, made in 1795 by John Russell, R.A., on a scale of nearly five feet to the moon's diameter. Photographic reproductions of this have appeared in the *Monthly Notices* of the Royal Astronomical Society and elsewhere. It is reproduced in colours in the *Illustrated London News* for Oct. 18 on a scale about one-sixth of the original. Mr. Russell took extreme care to make his picture accurate, and his pencil studies of details of the lunar surface occupied him for ten years. Several of these are also reproduced. In one of them he has given rein to his imagination; there is a well-known *Tête de Femme* at one extremity of the Bay of Rainbows, but the picture makes the likeness to a female figure much stronger than the reality. A modern picture-map of the moon in colours, by M. Lucien Rudaux, is given for comparison; this shows the disc fully illuminated, whereas Russell preferred to portray the gibbous phase, the terminator being near Kepler; he wished to have some shadows visible, to assist in showing the surface in relief.

Discoverer of Pluto.—Mr. Clyde Tombaugh's name has become well known through his discovery of Pluto at the Lowell Observatory last January. The *Scientific American* for October has an article by him. Until 1929 his principal employment was farm work, but his interest in astronomy dates from 1926, when he made his first telescope, an 8-inch reflector; he made quite a good 9-inch reflector in 1928; however, he ceased to be an amateur soon afterwards, for early in 1929 he was given a post at the Lowell Observatory. When the 13-inch Lawrence Lowell telescope arrived, it was placed in his charge to search for the planet the existence of which the late Prof. P. Lowell had foretold. Lowell had expected that it would be as bright as mag. 13; actually Pluto was of mag. 15. Its detection shows the thorough nature of Mr. Tombaugh's search.

Research Items.

The Aryans.—In the October issue of *Scientia* Prof. Pizzagalli publishes a review of recent discoveries in philology in relation to the question of the origin of the Indo-Europeans. In the study of linguistic prehistory the dominant and pivotal view now is that of ethnic substrata—the view that the Aryans, not one people, but a number of tribes speaking different dialects of common origin, advanced, not over an empty country, but among peoples of considerable number and of a certain degree of civilisation. Further, that these did not vanish before the invaders, but survived as a subject population which imposed much of its culture and language on the conquerors. M. Auban has endeavoured to show that Sumerian is an Indo-European language, but, apart from other arguments, this involves acceptance of the view that Indo-European has passed from agglutinative to flexional—a transition of which language affords no evidence. The Indo-European character of the Hittite language has a firmer foundation, as traces of Indo-European are more numerous. As regards a Dravidian origin, Slater holds that it was a species of lingua franca diffused by the commercial relations of the peoples of Europe, Asia, and Africa. This depends upon the view that holds to the Mediterranean origin of the Dravidians, an integral part of a dispersion extending from Ceylon on one side to the Basques on the other. These theories tend to place the centre of dispersal in Asia Minor and Mesopotamia, to reduce the Indo-European element in Indo-European culture, and to assume an agglutinative phase before the flexional which is represented by the Dravidian, Sumerian, and Hittite languages, whereas in reality, these languages and cultures at some stage of their history came under the strong influence of the Aryans in their rôle of conquerors. The Aryans' origin must be looked for somewhere within the range of distribution from the Baltic to the Persian Gulf, probably Iran.

Pedigrees of Retinitis Pigmentosa.—Two pedigrees of retinitis pigmentosa have been investigated by Dr. Usher and published in the *Annals of Eugenics* (April 1930). The pedigree of the first family had not been recorded previously; the second is presented in collaboration with Dr. Shennan, and is an extension of an earlier record by Hine. The former covers six generations, and includes some 243 members; it is of considerable value as an addition to the authentic family histories of this condition, and is a detailed record showing that although the symptoms of night blindness varied slightly in degree, they were remarkably constant in being exhibited very early in life, and that the afflicted members in spite of their defective vision lived to an advanced old age. The second pedigree presents certain unusual features, of which perhaps the most interesting is the late age of onset of the condition; it also appeared that early, and presumably congenital, deafness might be an alternative anomaly of the central nervous system among members of the family concerned. It might be anticipated that different individuals would exhibit variations in the intensity and age incidence of a hereditary condition even in one branch of a family, but it would appear that in this instance both modifying factors are determined by the constitution of the germplasm, and that the latter is quite evenly distributed among the several members of a stock. The first family record is characterised by early onset, which permitted the ultimate development of total blindness; the second is significantly different, in that defective vision was a manifestation of later years, and that blindness was seldom complete. It would therefore seem certain that heredity can not only determine the occurrence of a defect but also regulate with precision the actual rate of its development in the individual.

Lead-poisoning of Water-fowl.—In 1921 thousands of water-fowl died in Louisiana from a mysterious disease which was finally diagnosed as lead-poisoning due to the swallowing of spent shot in areas much frequented by sportsmen. During the past two winters a recurrence of mortality from this cause has been notified (*California Fish and Game*, vol. 16, p. 257, 1930). It is associated with particularly low water levels in the coastal region, which permit shallow-feeding ducks, such as mallard and pintail, to puddle in mud-bottoms which have been plentifully sprayed with scattered pellets by shore-shooters. Post-mortem examination of 18 birds showed the presence in every one of pellets of lead, varying in number from 1 to 24, and in each case post-mortem aspects of lead-poisoning were revealed. The pellets might easily be overlooked in a superficial examination, for frequently they were worn down to mere discs of small size. Death is caused by the assimilation of the comparatively thin outer surface worn from all the shot, and since the toxic action of lead is slow and the bird may retain its power of flight for two or three days after having consumed a lethal dose of shot, cases in which an apparently healthy bird is found carrying a considerable number of shot are explained. Unfortunately, there is still deposited, not only in the shallow waters of Louisiana, but also in those of many other States, lead shot which will continue to kill water-fowl for many years to come, and there is no possibility of employing remedial measures.

Temperature and the Breeding of Marine Animals.—Mr. Sven Runnström in *Bergens Museums Arbók* for 1929 (No. 10) ("Weitere Studien über die Temperaturanpassung der Fortpflanzung und Entwicklung mariner Tiere") continues his valuable studies on the influence of temperature on the reproduction and development of certain marine animals. His previous work on the subject was published in the *Arbók* in 1927, where it is shown that the first developmental stages are much more sensitive to changes of temperature than the later larval stages and the adult. The breeding temperatures arrived at experimentally agree well with those in natural conditions. The present research has to do with Mediterranean-boreal forms and was conducted both at Bergen and at marine stations on the Mediterranean, certain ascidians and echinoderms besides *Mytilus edulis*, the common mussel, being studied. The Mediterranean-boreal forms in the boreal region (the southern limit of which is the English Channel) are nearly all summer breeders, whilst those in the Mediterranean usually breed in the winter and spring, sometimes all the year round. The species studied live under conditions of very varied temperature, ranging from 3° to 27·5°. Except in *Mytilus edulis* the ten species investigated in the boreal region show a normal development from 8° to 23° and typical Mediterranean-boreal forms in the Mediterranean show the same temperature limits. Separate races occur in the two regions, breeding at different times. *Mytilus edulis* breeds in Bergen typically in spring at 4°–16°. In the Mediterranean the form *galloprovincialis* breeds in summer at a temperature of 8°–23°.

New Zealand Mollusca.—The *Transactions and Proceedings of the New Zealand Institute*, vol. 60 (quarterly issue), part 4, Dec. 1929, issued March 1930,

contains two interesting papers dealing with the Mollusca. In the first, Mr. C. E. R. Bucknill ("Further Microscopical Details of New Zealand Loricata") investigates the nerve terminals of various chitons and goes minutely into the structure of ocelli, megalæsthetes and micræsthetes. It is shown that although many of the megalæsthetes are destined to become eyes, a large number in certain forms remain permanently as megalæsthetes, the function of which is to secrete a glutinous substance or merely to excrete moisture, and are protrusible, the micræsthetes having chiefly a tactile function. These last are universally distributed and very simple in structure, outnumbering all other nerve terminals by fifteen to one on an average. In the second paper, "New Species of New Zealand Mollusca from Shallow-water Dredgings, part 1", Mr. A. W. P. Powell describes thirteen new species and founds two new genera *Benthocardiella*, in the family Condylocardiidae, and *Altispecula*, in the family Cerithiidae—the latter founded on a handsome South Australian deep-water shell with strong axial ribs.

Virus Disease of Plants.—A new method of attack has been used by the workers on virus diseases at the Rothamsted Experimental Station. They have realised that the virus should be studied in the environment in which it is most active, namely, the living host, and Dr. J. Caldwell has recently published results of the first part of his work on the "Physiology of Virus Diseases in Plants" (*Annals of Applied Biology*, vol. 17, pp. 429-443). He has studied the passage of the virus of yellow mosaic in the tomato plant, finding that the movement was inhibited by the treatment of part of the stem with chloroform and was also effectively controlled by steaming an area on the stem. There was no localisation of the virus on one side of the stem as might be expected from movement through vascular tissue after a one-sided inoculation, nor did the virus behave as did red ink or particulate substances, both of which passed across the open xylem vessels of the steamed area. It was concluded that the movement takes place in the living ground tissue of the plant.

Slime Fungi in Soil.—C. Thom and K. B. Raper direct attention to the constancy with which amœboid forms of the Myxomycetæ or slime fungi can be obtained from samples of soil and from the decaying vegetation on the surface of the soil, in a paper in the *Journal of the Washington Academy of Science* (vol. 20, No. 15, Sept. 19, 1930). They suggest that the group of organisms may have been rather neglected in studying the soil population, and that the amœbæ of the soil, which have received very considerable attention from soil workers of the last generation, may usually include a strong representation of this group, especially when the soil temperature is not too high (not above 18° C.). The plasmodia and motile amœbæ observed were generally obtained on mannite agar on which suitable samples of the soil or vegetable detritus had been placed; when sporangia were obtained the genus *Didymium* was usually identified.

Suffolk Mosses.—Thirty years have passed since the Rev. E. N. Bloomfield compiled his list of Suffolk mosses; a recent paper by Mr. A. Mayfield ("The Hepatics, Mosses, and Lichens of Suffolk", *Jour. Ipswich and Dist. Nat. Hist. Soc.*, vol. 1, pt. 2, July 1930, pp. 89-140) brings that list up-to-date. While it may be true that the county has been so well worked for mosses and hepatics that few additions will be made in the future, Mr. Mayfield's intensive study of his own parish, in addition to more extended field work, has yielded such excellent results as to indicate the need for the close study of other small areas in order to determine the distribution of what now appear to be rare species in the county.

Saxifrage Crosses.—A cross between *Saxifraga rosacea* ♀ and *S. granulata* ♂ (Marsden-Jones and Turrill, *Jour. Genetics*, vol. 23, No. 1) has given results of unusual interest. These species belong to different sections of the genus. The *rosacea* was obtained from western Ireland, and the *granulata* from Coulston, Wilts. *S. rosacea* is evergreen, while *granulata* forms bulbils. There are also differences in the shape of sepals, petals, and fruit. The F_1, numbering twenty-six plants, was uniform except for one plant with a tendency to form tubular flowers and poor stamens, and this generation more nearly resembled the male parent in most features. The F_2 and F_3, numbering several hundred plants, also showed great uniformity except for the occurrence of lobed or staminoid petals in certain plants. The absence of segregation led to the conclusion that this hybrid form, which is named *S. potternensis*, was tetraploid. This surmise was confirmed by R. O. Whyte, who publishes an account of the cytology in the same issue of the *Journal of Genetics*. The count of 16 as haploid chromosome number in both parent species is confirmed, while the F_2 hybrids have 32-36. Study of the meiosis in F_2 plants indicates that the doubling takes place through a suspended heterotypic or 'semi-heterotypic' division. Investigation of the ovule, petal, and anther deficiency in flowers of this Saxifrage, as well as in several other genera, leads to the view that such deficiencies are a result of the competition for nutriment between anthers and ovules when they attempt to develop simultaneously instead of, as usual, successively. This is regarded as the state of affairs in, for example, the flowers of *Ranunculus acris*, which are deficient of anthers. If the nutrition level falls below that necessary for the optimum metabolism rate for anthers and ovules in the developing flower, then one of the developmental phases may be affected, producing anther or ovule deficiency or petal deficiency with abnormal floral types.

Orogenic History of Alaska.—The geological history of Alaska involves that of no fewer than five highland areas that are considered to be more or less independent of one another in their mode and time of origin. These are: (*a*) the southern coastal ranges; (*b*) the Alaska range and its continuation into the Alaska peninsula; (*c*) the central highlands of the Yukon-Porcupine area and Seward peninsula; (*d*) the Kuskokwim highland of south-west Alaska; and (*e*) the Brooks range of the north. In the *Amer. Jour. Sci.* for August 1930, J. B. Mertie, jun., summarises the fund of structural and stratigraphical data which is now available, with the view of elucidating the problem of orogeny in each of the above five terrains. For the southern coastal ranges the history may be summarised as follows. *Lower Jurassic:* submergence accompanied by great outpourings of basic lavas, with partial uplift towards the end followed by re-submergence. *Middle and Upper Jurassic:* continued submergence accompanied by granite intrusions. *End of Jurassic:* epeirogenic uplift followed by a period of erosion. *Late Lower or early Upper Cretaceous:* partial submergence, probably with injection of granitic rocks. *Early Eocene:* uplift followed by the formation of coal measures which, later, were deformed. *Pliocene:* regional uplift and mountain building with outflows of basic lavas. *Quaternary:* Continued uplift. Detailed histories on similar lines are given for the other four areas.

Friction on an Aerofoil.—In the October number of the *Proceedings of the Royal Society*, A. Fage and V. M. Falkner describe a determination of the friction on the surface of a Joukowski aerofoil. Three methods were used: in the first, the velocity in the air at a few thousandths of an inch from the surface was found by the aid of very small surface tubes, and the friction calculated from the velocity gradient; in the second, the frictional drag was calculated from the difference between the total drag, estimated from the total-head losses in the wake, and the drag due to the normal pressures on the surface; and in the third, the friction was derived from considerations of the momentum and pressure changes in the boundary layer. The values obtained were concordant to a few per cent. The distribution of friction over the surface was such that it had a maximum intensity at a short distance from the nose, and a second and larger maximum just beyond the first, the relative positions of which on the upper and lower surfaces varied with the incidence. The first maximum was ascribed to laminar flow, and the second to turbulent flow in the boundary layer.

Absorption of Light by Xenon.—The absorption spectra of liquids and solids exhibit wide continuous bands which must be related in some way, which is at present not clear, to the properties of the atoms and molecules of the materials. An investigation of absorption by xenon, which might be expected to give simple results from its inert nature, is described by Prof. J. C. McLennan and Mr. R. Turnbull in the October issue of the *Proceedings of the Royal Society*. The fullest results have been obtained with the gas. The longer of the two resonance wave-lengths for this ($^1S_0$ - $^3P_1$) is in the middle of the Schumann region at 1469 A., and at a pressure of a few millimetres of mercury line-absorption takes place there. As the pressure is increased, a band develops with strong asymmetry towards longer wave-lengths, and at fifty atmospheres extends between 1584 A. and 1428 A. The behaviour of xenon is thus similar to that of mercury, with which an asymmetrical development of a band takes place round the singlet-triplet line at 2537 A. in similar circumstances. The important question of whether symmetrical broadening occurs about the $^1S_0$ - $^1P_1$ xenon line at 1293 A., as it does with the analogous mercury line at 1850 A., according to the evidence available, is left open. A less complete description is also given of the absorption by the condensed phases of xenon, from which it appears, *inter alia*, that liquid xenon has a temperature of maximum optical density between - 10° C. and - 110° C.

Theory of Pulling a Synchronous Motor into Step.—In connexion with the problems of the parallel running of alternators and the pulling into step of synchronous motors, the main difficulty in finding mathematical solutions lies in solving the differential equations which express the motion. Lord Kelvin and Prof. James Thomson, so far back as 1876, described an integrating machine for solving differential equations with variable coefficients. Modern electrical and mechanical devices have now made possible the construction of a practical integraph of this type. Dr. Bush and others at the Massachusetts Institute of Technology have perfected such an instrument, which gives the solution in about a minute's time. In the *Journal of the Institution of Electrical Engineers* for September, H. E. Edgerton and F. Z. Zak discuss the problem of what happens when a synchronous motor is pulled into step. The results are put in a simple form, convenient for practical use. The relationships between the values of the field current, the motor torque, and the slip, which determine whether a given load having a definite flywheel effect can be brought into synchronism or not, are found. Numerical examples are given which prove the practical value of the equations they give.

Germanium Monoxide.—Although indications of the existence of the compound GeO were obtained by Winkler in 1886, no systematic investigation of the substance has been made. In the September number of the *Journal of the American Chemical Society*, Dennis and Hulse describe the preparation of this oxide, and of the corresponding sulphide, GeS, also described by Winkler. The anhydrous oxide is jet-black and crystalline, stable in air and towards acids and alkalis. Hydrogen chloride and chlorine attack it when heated, forming germanium chloroform, $GeHCl_3$, and $GeCl_4$ and GeO_2, respectively. No evidence of the formation of $GeOCl_2$ was obtained. The sulphide was obtained as a red amorphous powder and in black crystals.

Molecular Weight of Lactalbumin.—Besides casein, the chief protein constituent of cows' milk is lactalbumin, which occurs to the extent of about 10 per cent of the casein. Investigations have shown that the behaviour of casein is very complicated, and it was of interest to see whether the marked instability of casein is also found in the lactalbumin and is a characteristic of milk proteins. In the September number of the *Journal of the American Chemical Society*, Sjogren and Svedberg describe experiments with the ultra-centrifuge which show that lactalbumin is not homogeneous with regard to molecular weight, and thus resembles casein. Experiments on the direct ultra-centrifugal analysis of milk are also described. The values for the molecular weight of lactalbumin varied between 12,000 and 25,000, and it is regarded as probable that lactalbumin is not present in milk but is formed during the process of 'purification', especially by the action of concentrated ammonium sulphate, being produced from a material of molecular weight not exceeding 1000.

The Fractionation of Gliadin.—When wheat flour is kneaded with water, the starch is removed and a protein, gluten, remains. This was separated by Einhoff in 1805 into a portion (gliadin) soluble in alcohol of moderate concentration and a portion (glutenin) which is insoluble. Although much careful work on gliadin has been undertaken, it is not certain whether it is a single protein (as Osborne and his co-workers believed) or not. In vol. 18, part 2 (1930), of the *Comptes rendus* of the Carlsberg Laboratory, a long and detailed account of this problem is given by Haugaard and Johnson. Their experiments, although they have not given a final solution of the problem, lead them to assume that gliadin constitutes what Sörensen calls a coprecipitation system, that is, an association of substances combined in a mutually reversible manner in some way so that the system as regards osmotic respects behaves as a single substance, yet in which an exchange is possible between the components when changes in the state and composition of the solution (temperature, salt content, hydrogen ion activity, etc.) give rise to it. If such a component exchange is given the opportunity of forming a sparingly soluble or insoluble coprecipitation system under the new conditions, it will naturally form and precipitate out. The method of fractionation of gliadin used did not permit of the preparation of the constituents of the coprecipitation system in the pure state, but it was simple and did not appear to affect the fractions in any way.

Aspects of Carbohydrate Metabolism.

I. BLOOD AND URINE 'SUGAR'.

THE form in which carbohydrate circulates in the body is glucose: it is frequently of clinical importance to determine the amount of this substance in the blood, but estimation of blood-sugar may not be synonymous with determination of blood-glucose. Different methods of estimation give somewhat different results, but this is of little importance clinically, provided the same method is always used. It is, however, of some interest to inquire into the causes of these discrepancies and a certain amount of work has been recently devoted to this subject. After fermentation with yeast, blood still gives a residual reduction with oxidising agents, which is obviously not due to glucose: according to I. M. Rabinowitch (*Biochem. Jour.*, vol. 22, p. 753; 1928) the amount of the non-fermentable reducing substances present in normal or diabetic human blood is about 0·025 per cent expressed as glucose. It is very constant in the same individual, is not affected by insulin or by the administration of glucose by mouth, and is the same in venous as in arterial blood: in all these respects it shows a marked contrast with glucose.

F. K. Herbert, M. C. Bourne, and J. Groen have investigated the nature of the non-glucose reducing substances in human blood (*ibid.* vol. 23, p. 339; 1929; vol. 24, pp. 291 and 299; 1930). In the first paper the distribution of reducing substances between plasma and corpuscles was determined by several different blood-sugar methods. By those of MacLean, Hagedorn and Jensen, and Benedict, there appeared to be more sugar in the plasma than in the corpuscles; by those of Folin and Wu and Shaffer and Hartmann (as modified by Somogyi) the distribution was approximately equal; whilst when the Hagedorn-Jensen method was carried out on the Folin-Wu blood filtrate, there appeared to be slightly more in the corpuscles than in the plasma. Blood filtrates prepared by the tungstic acid method from whole blood or corpuscles reduced the Folin-Wu copper reagent in the cold, but not those from plasma; nor was such a reaction given by filtrates prepared by the use of colloidal ferric hydroxide or zinc hydroxide.

It appears, therefore, that the corpuscles contain non-glucose reducing substances which are precipitated by iron and zinc hydroxides but not by tungstic acid: they are not fermentable with yeast. The most important of these is probably glutathione, since uric acid, creatine, creatinine, and ergothioneine are present in too small concentrations to affect the estimation of blood-glucose. In the second paper of the series it was shown that when pure glutathione was estimated in the presence of 0·1 per cent of glucose, it produced a reduction of 56 per cent of that given by a corresponding amount of the latter when the Hagedorn-Jensen method was used, of 39 per cent with the Shaffer-Hartmann method, and of 20 per cent with that of Folin and Wu: it failed to affect Benedict's reagent. It was also shown that a zinc hydroxide filtrate, provided the precipitation had been carried out at a slightly alkaline reaction, contained none, whilst all the glutathione present passed into a tungstic acid filtrate. The third paper applies these results to blood, and a description is given of a new method of precipitating the proteins: the corpuscles are kept intact by using sodium sulphate as diluent instead of water, the precipitation being carried out by means of tungstic acid. The four methods of blood-sugar estimation agreed when compared on zinc hydroxide or the modified tungstic acid filtrates; on the original tungstic acid filtrates higher values (except with Benedict's method) were obtained and the methods disagreed. The discrepancies could all be explained by the known reducing powers of glutathione in the presence of the reagent used. The amount of this substance in the blood is about 0·05 per cent, a higher figure than that given by Rabinowitch.

J. M. Gulland and R. A. Peters (*ibid.* vol. 24, p. 91; 1930) have investigated the nature of the reducing substances in pigeons' blood. The Hagedorn-Jensen method was used: relatively high values for blood-sugar were obtained, but it was found that even after the injection of insulin, or after the blood had been exposed to anaerobic glycolysis, a residual reduction of 0·07 per cent was still observed. Deduction of this figure from the 'blood-sugar' value indicated that the true glucose of the blood was not very much higher than that of mammals. The residual reducing substances were almost confined to the corpuscles: about half of them reduced the ferricyanide in the cold, suggesting the presence of sulphydryl groups. It was found that, by this method, the reducing power—in terms of glucose (100)—of uric acid was 53, of glutathione 17, and of ergothioneine 56; by the ordinary Hagedorn-Jensen method glutathione was found to be equivalent to 45 of glucose (agreeing with Herbert *et al.*). From these estimations, and others carried out on tungstic, trichloroacetic, and zinc filtrates, it was concluded that the non-glucose reducing substances in pigeons' blood are ergothioneine, uric acid, creatinine, creatine, and one or more unidentified compounds, possibly a purine-carbohydrate or a phosphoric ester.

E. N. Allott (*ibid.*, vol. 22, p. 773; 1928) has shown that the rates of utilisation of α, β, and $\alpha\beta$ glucose when injected into the veins of rabbits are the same. O. J. Nielsen (*ibid.*, vol. 22, p. 1490; 1928), by estimates of the blood-sugar at intervals of 1–5 min., has shown that it is not, in man, subject to violent fluctuations, remaining fairly constant or falling or rising steadily according to the conditions at the moment: the observations were carried out after fasting and after the ingestion of food or glucose on both normal and diabetic subjects.

Two other papers on carbohydrates may be referred to briefly here. C. Rimington (*ibid.*, vol. 23, p. 430; 1929) succeeded in isolating a carbohydrate derivative from alcohol-denatured serum proteins, by hydrolysis with baryta, treatment with lead acetate, and precipitation with ammonia: the lead ammonia precipitate was dissolved in weak acid, the lead removed, and the filtrate treated with mercuric chloride solution: after removal of metals the solution was concentrated and the carbohydrate precipitated with methyl alcohol and ether. The yield was 2 per cent. On analysis it was found to contain 4·1 per cent nitrogen, and molecular weight determinations indicated that it was a disaccharide, having the empirical formula $C_{12}H_{23}O_{10}N$; further investigation showed that it was a disaccharide of glucosamine and mannose. Both albumin and globulin yielded the same derivative, and it was also obtained after tryptic digestion of serum protein. It is considered probable that the mannose is attached to the nitrogen atom of the glucosamine. From the amount present the minimum molecular weight of the albumin or globulin must be of the order of 17,000, a figure which agrees with estimations made by other methods. It is possible that this carbohydrate plays some part in the immunological reactions of the plasma proteins.

H. Sobotka and M. Reiner (*ibid.*, vol. 24, p. 394; 1930) have investigated the configuration of certain sugars by means of the differences in their reducing powers for the ferricyanide reagent of Hagedorn and Jensen. Their results lead to the conclusion that in aldo- and keto-hexoses the configuration between the third and fourth carbon atom is the determining factor: in aldopentoses the configurations between these two atoms and the second and third share the influence on the reducing power. The *trans* arrangement of OH is more active than the *cis*.

The question of the nature of the reducing substances in urine, especially in human beings, has always aroused interest. It is generally held that small amounts of glucose are normally excreted; during lactation, lactose may appear, whilst the excretion of a pentose is a rare abnormality. J. Patterson (*ibid.*, vol. 20, p. 651; 1926) considers, however, that the carbohydrate in normal urine is not glucose, since it is not fermented by baker's yeast and forms a phenylosazone of different crystalline form and properties from those of glucosazone, although its analysis suggests that it is a hexosazone. Hydrolysis of urine usually sets free a fermentable reducing sugar. A. Hassan, however, considers that glucose is present in normal urine, although accompanied by another sugar which forms a different osazone (*ibid.*, vol. 22, p. 1332; 1928). Both authors agree that interfering substances must be removed before attempting to form an osazone; Patterson employs the mercuric nitrate reagent and Hassan charcoal. The latter author also found that the number of urines giving typical glucosazone crystals as well as mixed crystals, instead of the latter only, was increased following a meal but not following the administration of glucose alone.

Social Biology.*

DARWIN'S "Descent of Man" was a challenge to the complacent dualism which had permitted utilitarian science and humanistic philosophy to pursue an independent course from the days of the schoolmen to the middle of the nineteenth century. To-day it is evident that the social sciences can no longer progress within the framework of a philosophical tradition brought into being by the conditions of the city State and nurtured from Abelard to Kant in servile association with the requirements of apologetics. Economic science has already severed its moorings to moral philosophy. There is a growing disposition among other branches of social science to do the same. To-day the application of scientific method to the study of human society is philosophically guaranteed by the generally accepted conclusion that millionaires and metaphysicians, statesmen and seventh-day adventists are products of the same secular agencies as have fashioned the rest of the brute creation. The far-reaching implications of the change in outlook which Darwin's doctrine has brought about are becoming more apparent in our time, because biologists are now undertaking the analysis of the characteristics of conscious behaviour in animals and the behaviourist school of psychologists is applying the new methods to man himself.

Man is an animal as the ant is an animal. The biologist as a biologist confines his attention to those characteristics which ants and antiquarians have in common. The sociologist confines his inquiries to certain characteristics which distinguish men and women from ants and all other animals. Their respective fields of investigation overlap in the attempt to define what characteristics of human society are determined by those characteristics which men share with all other animals and what characteristics of human society are referable to characteristics which distinguish man as one species of animal from all other species of animals.

We must be prepared to recognise that issues which made the first claim on the attention of men like Huxley, Galton, and Spencer are no longer topical. The misguided opposition of the Churches compelled biologists of Darwin's generation to concentrate on emphasising the characteristics which we share with other animals. Social biology has now to undertake the task of defining in biologically significant terms the characteristics which distinguish man as one species of animal from all other species of animals. The work of physiologists like Sherrington and Pavlov is opening the way to a biological interpretation of those peculiarities which are most diagnostic of the human species. A well balanced view of the rôle which inheritance and social tradition respectively play in determining differences which distinguish different social groups will only be possible when the biological study of behaviour and the methods of the geneticist can be brought into working harmony.

The great danger lies in undue haste to establish conclusions which may be made the basis of legislation. The genetic basis of occupational and racial stratification in human societies is a problem which calls for discipline, detachment, and restraint. Nothing could make the exercise of these wholesome virtues more difficult than to bring issues which are still problematical to scientific workers before the forum of political controversy. Much research directed to elucidate genetic variations in human communities has been vitiated by a failure to envisage the complexity of the problem. A genuine scientific analysis of genetic variation in human society must be sustained by the recognition that human society is a unique biological phenomenon, inasmuch as the family is a unit for the cumulative communication of old and new environmental stimuli as well as a group delimited by genetic affinity. The pre-eminent need of the moment is investigation rather than propaganda. The first task of the social biologist is not to advocate the sterilisation of the unfit but to undertake the sterilisation of the instruments of research before operating on the body politic.

In our own generation the population problem embraces a variety of issues in which the sociologist and the biologist have a common interest. A clear appreciation of the biological issues necessitates the prosecution of research into the physiology of reproduction, the genetic basis of human behaviour, and the incidence of changes in fertility. The analysis of this intricate problem will not be facilitated by an unduly alarmist attitude. The sceptical inquirer may approach the differential fertility of the social classes which has accompanied the decline in the birth-rate as a conundrum rather than a catastrophe. We have inadequate scientific evidence to justify the belief that extensive genetic differences do distinguish the social classes. If we had such knowledge it would be necessary to ascertain how such differences are transmitted before justifying the belief that a temporary disparity in fertility will necessarily produce

* Substance of an inaugural lecture delivered by Prof. Lancelot Hogben at the London School of Economics and Political Science on Oct. 23.

significant social consequences. The German and Swedish data suggest that contraceptive practice is rapidly spreading to all sections of the community, so that differential fertility may be a problem which will solve itself without legislative interference. On the other hand, if this transpires to be the case, it is possible that European communities will be faced with a rapid decline in general population, which will create a new constellation of social problems for legislative treatment. The decline in the birth-rate brings us face to face with the fact that human society is entering upon what Mr. J. B. S. Haldane has called the era of biological invention, and the institution of a chair of social biology is an implicit recognition of the impending change. The rapid progress now being made in physiology makes it unlikely that in the near future human society will be in a position to regulate the reproductive process to an extent and in ways hitherto unimagined and unimaginable.

In many directions it will be necessary for the social biologist to co-operate with pure sociology in ascertaining the significant factors which operate in determining the growth of human populations. On the other hand, social biology cannot develop fruitfully if it isolates itself from the methods of experimental inquiry. By the very complexity of the genetic problem social biology is committed to create a framework of biological research and teaching in which a new type of social psychology can develop. For the same reason it is entrusted with the experimental analysis of aspects of the physiology of reproduction too long neglected by medical science.

Periodicity of Locust Invasions.*

WHILE the technical methods of controlling locusts are well developed and very effective, a successful organisation of anti-locust campaigns meets with many difficulties. The main difficulty lies in the fact that locusts are not a permanent pest, but may be absent from a country one year, and appear in enormous swarms in the next. For example, the Desert locust, a species alluded to in the Bible, invaded the whole of north and east Africa, Persia, India, Iraq, Palestine, and Turkey in 1914-16 and then nothing was heard about it for more than ten years. In 1926-27 a new outbreak started, and by 1929-30 Africa from Tanganyika to the Mediterranean, and south-west Asia so far north as Transcaucasia and Turkestan, were overrun by devastating swarms.

Such sudden outbreaks involving whole countries find some of them not fully prepared to meet the danger, and during the recent invasion extraordinary efforts were required to save the crops. An effective organisation of an anti-locust campaign cannot be improvised at a moment's notice, while it is clearly impossible to keep the organisation in readiness during long intervals between invasions.

The key to the solution of the locust problem is therefore to find out the laws governing periodic outbreaks of locusts. Recent work in this direction in Russia, South Africa, Sudan, and elsewhere proves that the periodicity of locust outbreaks is intimately connected with the fact that all known species of locusts occur in two forms or phases. These forms differ from each other in a number of structural and colour characters, but more particularly in the habits. During the intervals between outbreaks locusts are represented by the solitary phase, which is a harmless grasshopper without definite social habits. When the outbreak begins, the solitary phase is transformed into the gregarious one: the individuals of this phase form dense swarms and undertake long migrations. Experimental work on phases has shown that the solitary phase can be turned into the gregarious one, if the locusts are kept in a crowded condition; conversely, one can obtain the solitary phase by breeding gregarious individuals under isolated conditions.

Periodic outbreaks of locusts depend, then, on the cyclic transformation of these insects from one phase into another, and back again. The actual factors causing and favouring the transformation are still insufficiently known, but it is clear that the problem of the successful control of locusts cannot be solved until these factors are thoroughly investigated.

A special Committee has been appointed recently by the Government to consider the locust problem, and it was decided to organise exhaustive investigations into the question of periodic outbreaks and their causes. It is hoped that the actual work will begin shortly, and this concentrated scientific attack on locusts should produce results of great practical value in the shape of means of foreseeing and preventing locust invasions, which would mean an enormous saving in crops, human energy, and money for a large number of countries affected by the plague.

* Substance of a paper read by Dr. B. P. Uvarov before Section D (Zoology) of the British Association at Bristol on Sept. 9.

Research in the Electrical Industry.

MR. C. C. PATERSON, president of the Institution of Electrical Engineers, gave his inaugural address on Oct. 23. His subject was research, and he illustrated it with many brilliant and novel experiments. It rivalled the address on 'pressure rises' given by the late W. Duddell in 1913, when many interesting experiments were shown. He pointed out that whichever way we look in the domain of electrical engineering, whether in lighting or heating, in electro-chemistry or electro-medicine, in radio-telephony, in photo-electricity, or in heavy engineering, there are new advances every day, and dramatic discoveries and achievements rapidly succeed one another. As each discovery from the researches of physicists, metallurgists, and chemists comes to the engineer, he tries to assimilate it and turn it to practical use. There is a serious risk, however, of treating the old problems—often only half understood—as if they are already solved. Engineers are too often content with the knowledge of the art as they find it, and allow new extensions of the industry to be built on an insecure foundation of half-truths and empiricism. The old subjects need research as much as the new, and the most difficult problems are often those which the last generation has thrown aside in its hurry to grasp and exploit the next new thing. Mr. Paterson advocated research on many of the old-established usages in the industry. In his opinion, this would open up many new avenues of advance.

Mr. Paterson said that the distinction between pure and applied research is only one of ultimate

object. The ideal which inspires every one working in research is the substitution of knowledge for empiricism, and this finds as true an expression in industry as in those research institutions where the labours are furthest removed from practical utility. The measure of purity of research is determined by the spirit of the worker. He who uses his research talents in order that he may gain the prestige of priority in discovery is no more exalted than he who seeks to understand enigmas which are preventing a product from becoming useful to mankind. The desire to explain the mysteries of the world is the impulse of the researcher; it is the way in which the knowledge is used that purifies or debases. Empiricism has an essential place in almost every industrial process, because schedules and specifications can only be based on theory and principles so far as these are known, and the rest has to be rule of thumb. In addition, the schedules must be such that people who operate them need only follow them blindly and empirically. As an example, Mr. Paterson mentioned the controversy about the permissible voltage variations at a consumer's terminals: he pointed out that the effect of increasing the permissible variations would be to neutralise much of the good work done by manufacturers. He suggested that there should be a joint examination, by the supply industry and the manufacturers, of the problem.

Speaking of the problem of electric heating, Mr. Paterson considered it is largely a metallurgical one. The alloys used for the resistance wires are generally of nickel and chromium. These alloys are suitable because the oxide layer formed on their surfaces when heated in air is highly protective. Once a certain thickness has formed, further oxidation of the underlying metal proceeds very slowly. The suitability of an alloy is determined by the protective and adherent properties of the oxide rather than by the properties of the alloy itself. So far as progress in electric lighting is concerned, the luminous efficiency of the modern tungsten filament gas-filled lamp is not likely to be greatly exceeded. The actual efficiency is about 18 lumens per watt, where 12·57 (4π) lumens are emitted by a uniform point source of one candle power. Theoretically, 670 lumens per watt could be obtained by transforming power directly into light of maximum visibility. The light obtained, however, would be monochromatic. It would be quite unsuitable for general illumination, as it would be of a yellowish-green hue. Mr. Paterson showed a gaseous discharge tube, first tried in the United States and developed by Prof. Pirani, of Berlin, which operates at ordinary voltages and gives an efficiency up to 50 lumens per watt. He showed that if we use two of these tubes, one filled with sodium and the other with neon gas, the combination gives a light akin to candle-light. If we add a mercury vapour tube we get a fair approximation to daylight. There is room for progress to be made in this direction.

African Ethnology and Archæology.

SEVERAL communications from field workers in Kenya, Rhodesia, and South Africa were made to Section H (Anthropology) of the British Association at the recent Bristol meeting. Mr. L. S. B. Leakey gave a detailed account of the system of land tenure among the Kikuyu. One great cause of misunderstanding between the incoming white races and the natives is the different way in which each looks at the ownership of land; and it was felt that such studies as that made by Mr. Leakey, who speaks Kikuyu and has worked with Kikuyu people for many years, should help to bridge this gulf.

Mr. Leakey also gave an illustrated account of the pottery found with stone age cultures in Kenya. A striking feature is the discovery of pottery *in situ* in the lower part of the Upper Aurignacian deposits, at a depth of 28 feet from the original modern floor surface, and beneath a big series of undisturbed strata. Associated with the pottery were tools of a Mousterian type, an industry belonging in Kenya to the second division of the Gamblian pluvial just after its maximum. In view of the absence of pottery finds in Europe in association with Palæolithic cultures, the discovery opens again the question as to whether pottery may yet be found in other regions associated with Aurignacian implements; the evidence at present is entirely negative.

Mr. Leslie Armstrong, in a paper on "The Age of Man in Africa as demonstrated at the Victoria Falls", referred to a letter from Col. Fielden which was published in NATURE of Nov. 23, 1905, p. 77, directing attention to the "stone implements . . . present in profusion, both in the river gravels on the highest margins of the Zambesi valley and also spread broadcast, along with rolled gravel, on the basalt platforms of the ancient river channel below the Victoria Falls". Later, Mr. G. W. Lamplugh and Mr. Henry Balfour published papers on these implements. In 1929 Mr. Armstrong and Mr. Neville Jones of Buluwayo, as part of the work of the Rhodesian Archæological Expedition, investigated the occurrence and the zones of distribution, and were able to suggest the relation of the various types of artefacts to successive stages in the cutting back of the gorge.

The sequence of types was found to be precisely the same as in Europe. The earliest are pre-Chellean and occur in a more or less rolled condition over the whole area examined, which extended from the present falls to the fifth gorge. Beyond the fourth gorge, only tools of this type occur and they were obviously left there by the river when the position of the falls was on the line of the fifth gorge. Similarly, Chellean, Acheulean, and Mousterian tools occur in succession back to the area of the first and second gorges. Since the pre-Chellean tools were deposited by the river, the gorge, which is nowhere less than 400 ft. in depth and 100 ft. in width, has been excavated by the Zambezi for a distance of five miles by the opening out of lines of faulting and shrinkage cracks in the basalt. A long period of time must be allowed for this erosion. But there is geological evidence that the erosion was not continuous and that there was an arid period when the Zambezi river was almost, if not completely, dried up, and at least one arid and one pluvial period have occurred since the implements of Acheulean type were dropped by their users near the river and washed into the gravels. Mr. Armstrong therefore concludes that the African series of lower Palæolithic stone implements is probably a whole period earlier than their European parallels, basing his belief on the equation of the pluvial periods of Africa with the glacial epochs of Europe.

A paper approaching the problems of the history of the south-eastern Bantu from a new point of view was read by Mr. A. J. H. Goodwin. He has worked among the AmaMpondo, and studied their royal regimental system. This system is based on the fact that when the 'Great Wife' of a chief is chosen, generally from the point of view of the value of her family as allies, her

son is heir to the chieftainship, and voluntary retainers attach themselves to him, thus forming the nucleus of a royal regiment. Mr. Goodwin gave details of the generation-regiments of the AmaMpondo, and showed how such details might be used as evidence for dating battles, since native historians carefully remember the names of the regiments present at battles. The Rev. W. A. Norton has attempted to date the regiments of the Ba Suto, but as yet nothing of this sort has been done for the south-eastern Bantu. Mr. Goodwin's paper also interested ethnologists, since it forms another link binding the eastern Bantu into a whole, the generational regimental system being well known everywhere farther north.

Action of Cinchona Alkaloids in Malaria.*

ALTHOUGH three centuries have elapsed since cinchona bark was introduced into European medicine for the treatment of malaria and it is nearly a century since the last of the four alkaloids—quinine, quinidine, cinchonine, and cinchonidine—which form the active constituents of the bark was discovered, there are still numerous problems to be settled in connexion with the use of the bark and its constituents in malaria. Until recently, chemotherapeutical work in this disease has been hampered by the fact that the relative values of drugs could only be investigated by extensive clinical trials in malarial countries. Much work of this kind has been done in India and Malaya by MacGilchrist, Acton, Fletcher, Sinton, and other British experts in tropical medicine, mainly to ascertain whether the present policy of concentrating on quinine as the only valuable cinchona alkaloid for the treatment of malaria is sound. Work of this kind is expensive and difficult, and final conclusions have not yet been reached.

Birds share with man susceptibility to malaria, and in recent years a method has been worked out of using them for testing new anti-malarial drugs. Facilities for such tests having been provided in Great Britain by the Chemotherapeutical Committee of the Medical Research Council, Dr. Henry, in association with Mr. J. A. Goodson, has been able to have the four cinchona alkaloids referred to above, together with a large number of their chemical derivatives, tested by Dr. Macfie in bird malaria. The results of this preliminary work support the conclusions arrived at from clinical trials that quinine and quinidine are more efficient than cinchonine, but the value of cinchonidine is still uncertain. Of the derivatives of quinine tried, the most promising is hydroquinine, which in these preliminary tests gave better results than any other drug examined. On oxidation, quinine is converted into an acid, quitenine, which is inactive in malaria, but it has been shown that activity is regained when the acid is esterified, and that in a series of such esters activity is slowly increased as the series is ascended, until at butyl and amyl esters the preparations begin to be curative instead of merely retarding the development of the malarial parasite.

In various tropical parts of the British Empire other drugs than cinchona enjoy local reputations as cures for malaria; for example, Alstonia bark in West Africa, the Far East, the Pacific Islands, and sub-tropical Australia, akuamma throughout Africa, and greenheart bark in British Guiana. All these also contain alkaloids, which have been tried in the course of this work, but the Alstonia alkaloids alone have shown any activity in bird malaria.

* Substance of a paper read by Dr. T. A. Henry before Section B (Chemistry) of the British Association at Bristol on Sept. 18.

University and Educational Intelligence.

CAMBRIDGE.—Sir James Jeans will deliver the Rede lecture at 5.30 P.M. on Nov. 4, taking as his subject "The Mysterious Universe".

The Appointments Committee of the Faculty of Engineering has appointed R. H. Angus, of Sidney Sussex College, to be University demonstrator in engineering.

The Appointments Committee of the Faculty of Physics and Chemistry gives notice that the Humphrey Owen Jones lectureship in physical chemistry is vacant owing to the appointment of Dr. E. K. Rideal to be professor of colloidal physics. Intending candidates for the Lectureship should send their names to the chairman of the Faculty Board of Physics and Chemistry, the Master of Pembroke College, not later than Nov. 12.

The Managers of the Balfour Fund, with the approval of the Faculty Board of Biology 'A', have made a grant of £150 from the fund to L. C. Beadle, of Pembroke College, for research on the biology of the East African Lakes.

EDINBURGH.—Sir James Barrie was installed as Chancellor of the University on Oct. 25 and conferred honorary degrees on Sir Thomas Holland, Principal of the University, and Sir J. J. Thomson, Master of Trinity College, Cambridge, among others.

LONDON.—The title of emeritus professor of electrical engineering in the University has been conferred on Prof. Ernest Wilson, on his retirement from the University chair of electrical engineering at King's College.

THE Council of the Institution of Naval Architects has awarded the Yarrow Scholarship in Marine Engineering (1930) to Mr. W. J. Reynolds, of Messrs. Alexander Hall and Co., Aberdeen. The Scholarship is of the value of £100 per annum and will be held at the University of Glasgow for four years.

"THE day of science is here in commerce as in industry." These words sum up the purport of Sir Francis Goodenough's paper read before section L (Education) of the British Association at Bristol on the subject of "Education for Business." No greater service could be rendered by the Association at this time than to promote the general recognition of the truth that scientific methods are imperatively demanded alike in the fields of production, management, and marketing. Scientific research is needed not only into methods of manufacture, handling and transport and methods of management, but also into methods of selling and the possibilities and requirements of the world's markets. In technical education for production there has been a great advance in the past twenty years, but education for marketing has not kept pace. Commerce has not hitherto been recognised as a science, and this vitally important business has been regarded too much as something people can 'pick up' as they go along. In the highly competitive and increasingly scientific world of to-day, it is essential that British commerce should find recruits endowed with "character *plus* brains raised to the highest power by education". There must be a general recognition of these facts and a determination on the part of all concerned to raise high the standards of efficiency and probity in the conduct of British commerce, to the benefit of all engaged in it and to the credit of the nation as a whole. So will be dissipated the still surviving prejudices which have for generations imposed a social handicap on those who follow a 'commercial' career and operate despite the congestion existing in other professions mistakenly regarded as more honourable.

Historic Natural Events.

Nov. 2, 1664. Great Plague of London began.—For some years London had been almost free from the bubonic plague, but an outbreak of great intensity began in the autumn of 1664, probably spreading from Holland. The first cases occurred on Nov. 2, and a few more in the following winter, which was severe. In May 1665 the epidemic became more noticeable and spread slowly through the City. The numbers of deaths reported from this cause were 43 in May, 590 in June, 6137 in July, rising to 31,159 in September. The total number reported was more than 68,000, and there were probably many thousands more which were kept secret. The population of London at the time was less than half a million, and of these, two-thirds fled to escape the contagion (incidentally spreading it widely over the country), so that of those who remained, nearly half died. The condition of London on Sept. 20, 1665, was described by Pepys: "But Lord! What a sad time it is to see no boats upon the River; and grass grows all up and down White Hall court, and nobody but poor wretches in the streets!" It was not until the cold weather of November and December 1665 that the plague abated and the refugees returned.

Nov. 2, 1898. Floods in the Lake District. As a result of heavy rains during a gale on Nov. 2, one of the worst floods on record occurred in the Lake District. At Kendal 3·6 in. of rain fell in two days, and the Kent rose 12 in. higher than the previous highest level of 1878, flooding the town to a depth of four or five feet and doing great damage. At Keswick nearly three inches fell in 24 hours, and Thirlmere being already at its full height, the water overflowed through Keswick, where many houses were flooded. Throughout Cumberland and Westmorland similar scenes occurred - bridges damaged or washed away, animals and poultry lost. At Cockermouth the Derwent rose to the highest point since the great flood of 1852 and the lower parts of the town were deeply flooded. Windermere reached a level a foot higher than the previous record.

Nov. 3, 1927. New England Floods. As a result of strong south-easterly winds blowing from the Atlantic, torrential rains fell over New England and eastern New York, exceeding 9 in. in several places. The ground was already saturated by excessive rain in October, and so heavy and extensive were the rains of Nov. 3 and 4 that destructive floods occurred even before the rain had ceased. The rivers exceeded their previous highest levels by several feet. At Montpelier, Vt., for example, the Winovski rose 16·5 ft. and there were 8-10 ft. of water over the whole business district. At White River Junction, Vt., the Connecticut rose 29 ft. in 24 hours. The greatest floods occurred at night, and the damage was estimated as more than 37 million dollars, more than 9000 persons were rendered homeless, and 88 lives were lost. Both life and property would have suffered far more but for the Weather Bureau warnings.

Nov. 4, 1926. Storm and High Tide on West of Scotland.—An unusually deep barometric depression travelled along the north coast of Ireland and north-eastward across Scotland on Nov. 4 and 5, causing severe gales. On the west coast of Scotland there was a very high tide. Many rivers overflowed their banks and caused considerable damage by flooding; roads were rendered impassable, in some cases railway services were delayed, and the telephone and telegraph services were dislocated.

Nov. 5, 1530. North Sea Storm.—On Nov. 4-5 a violent wind blew down many houses and trees in England. It was followed by a great inundation of the sea, which invaded the coasts of Essex and Kent and the Isle of Thanet, and was even more destructive in Flanders, Zealand, and Holland, where 25 towns and 24 smaller places were wholly or partly destroyed; Antorf and Antwerp suffered severely.

Nov. 6, 1909. Heavy Rain in Jamaica.—During the occurrence of an unusually strong northerly wind ('norther'), very heavy rains were experienced in the north-eastern part of the island, especially on Silver Hill. In eight days, Nov. 4-11, the total recorded was 135 in., of which 30·5 fell on Nov. 6. The rivers and gullies leading from the mountains were flooded, with much loss of property and some fatalities. At Radnor there was an immense landslide, which blocked the gorge of the Cascade River and raised the level of the water by 200 ft.

Nov. 6, 1916. Optical Phenomena near Amiens.—About 9.30 P.M., at Pont Noyelles, east of Amiens, there was a lunar halo of 22°, a horizontal circle or mock moon ring, and a halo of 90°. During the remainder of the evening gun flashes appeared as narrow vertical streaks centred 10° to 15° above the horizon, and a large red glow from a fire some miles away also appeared as a very large and fiery streak with a dark space at its centre, 32½° above the horizon. The appearance was described as "the Angel Gabriel crossing swords with the powers of darkness".

Societies and Academies.

PARIS.

Academy of Sciences, Sept. 22.—The president announced the death of Philippe Glangeaud, of the Section of Mineralogy.—**H. Vincent**: The comparative cryptotoxic power of the sodium salts of some of the saturated fatty acids. It has been shown in earlier publications that minute doses of sodium oleate, palmitate, or margarate can neutralise very active toxins (tetanus, diphtheria, dysentery), and that this is due to a physical action of the soaps. The antitoxic power of these soaps extends also to venoms, certain alkaloids, and metallic salts. The present communication gives an account of the antitoxic properties of the lower terms of the fatty acid series. The effects are very irregular and do not depend on the number of carbon atoms in the molecule, the solubility, or the melting point of the acid. There is no connexion between the cryptotoxic power and the surface tension of the solution.—**Luc Picart**: The singular cases in the calculation of orbits. **R. Chodat**: New researches on the gonidia of lichens.—**C. Raveau**: The utilisation of streams at the mouth. **Jacques Chokhate**: Continued algebraical fractions.—**Paul Alexandroff**: The geometrical analysis of the dimension of closed ensembles.—**Georges Giraud**: The integro-differential equations in conjunction with integro-differential conditions at the boundary.—**Radu Badesco**: A functional equation.—**Pierre Dupin**: The vibration of cylindrical tubes in water under the influence of alternating vortices.—**D. Rosenthal and M. Mathieu**: Mild steel welding in the electric arc. The strength of the weld is much increased if during the welding the metal is protected from oxidation. Examination by X-rays proves the existence of stresses in the case of the non-protected welds.—**Constantin Salceanu**: The magnetic double refraction of phenol, naphthalene, and of phenanthrene in the fused condition. The passage from the benzene ring to naphthalene and phenanthrene results in a large

increase in the magnetic double refraction.—**A. P. Rollet**: A silver borate. The compound described was proved to have the composition $Ag_2B_4O_7 + 2H_2O$. —**André Meyer** and **Mlle. Suzanne Mathey**: The volumetric estimation of acetone. The acetone is precipitated as $3HgSO_4 . 5HgO . 2C_3H_6O$ by Denigès reagent (acid mercury sulphate), the mercury in excess being titrated by Volhard's method.—**L. Bert**: A new method of synthesis of phenylpropargyl alcohol and its homologues substituted in the ring. With commercial cinnamyl alcohol as a starting point, a method giving good yields of phenylpropargyl alcohol is outlined. **H. Mémery**: The summer of 1930 and the solar variations.—**W. Moycho**: The formation of the pigment in *Bacterium prodigiosum*. The pigment (prodigiosine) always appears at the period of the strongest development: it is formed at the death of the bacterium and oxygen is necessary for its appearance.—**G. Dinulescu**: The biology of the horse-fly.—**Edouard Ducloux** and **Mlle. Georgette Cordier**: Researches on the treatment of experimental bovine anaplasmosis in Tunis. This disease is curable, provided that the treatment is commenced sufficiently early.

LENINGRAD.

Academy of Sciences (*Comptes rendus*, No. 5, 1930).—**A. Archangelskii**: Investigations of phosphorite deposits in Russia. **A. Borisiak**: *Ursus spelæus rossicus* nov. n. Description of a new race of *U. spelæus* from five almost entire skeletons found in a cave near Krasnodar, northern Caucasus.—**P. Lazarev** and **N. L. Rodzevic**: The phenomena of ionisation of gases during the photochemical reactions in solids.—**A. Rolmačev**: Some unexpected floristic finds in the central region of the Taimyr peninsula. —**N. Vassojevič**: Geological investigations in the region of the Djava mineral waters, southern Ossetia.—**K. Flerov**: The white muzzle deer (*Cervus albirostris* Przev.) as the representative of a new genus *Przewalskium*. A full description of the new genus.—**E. Cheissin**: A contribution to the binomics of infusoria parasitic in various invertebrates of the Lake Baikal.

Comptes rendus, No. 6, 1930. **A. Vinogradov** and **M. Neustrueva**: Manganese in insects (2). Quantitative determinations of manganese in a series of insects.—**A. Zachvatkin**: Vertical distribution and diurnal migrations of the zooplankton in Lake Baikal.—**A. Birula**: A preliminary communication on the Quaternary Carnivora of Crimea. Sixteen species are recorded from the Quaternary palæolitic deposits in Crimea, while the present-day fauna contains only seven.—**A. Kovanko**: A class of periodic generalised functions.—**N. Bogoliubov**: Approximation of functions by trigonometric summations.—**V. Ambarcumian**: A deduction from Dirac's theory of protons and electrons.

SYDNEY.

Linnean Society of New South Wales, Aug. 27.—**J. McLuckie**: On *Grevillea Gaudichaudii*, a supposed natural hybrid between *Grevillea laurifolia* and *G. acanthifolia*. The relation of the hybrids to the parents is shown by a graph based on the coefficients of divergence from the midparental reference point. —**F. A. Craft**: (1) The topography and water supply of Cox's River, N.S.W. The region forms part of the Nepean-Warragamba catchment area, and may be considered under the headings of tablelands, level valleys, and canyons or deep gorges. The tablelands have a thick mantle of soil or are forested; they supply water permanently to the streams, areas of swamp lands acting as storage grounds. The level valleys, which vary in elevation from 300 ft. to 3100 ft. above sea-level, are in parts water-bearing, but they depend largely upon the tablelands for permanent streams. The sides of the steep gorges have a very quick run-off. The continued permanency of the streams will depend largely upon the preservation of upland swamps and forests.—(2) Goulburn, a vital point on the New South Wales Highlands. Goulburn is situated on the tablelands between two series of deep gorges. The main routes leading from Sydney to Riverina and the Southern Tablelands pass along a narrow strip of undissected country to Goulburn, whence there is a divergence of routes. These take advantage of gentle radial valleys converging on the town, which is, therefore, a natural centre for communications and trade.

VIENNA.

Academy of Sciences, July 3.—**G. Koller** and **E. Kandler**: The constitution of cetraric acid.—**G. Koller** and **W. Passler**: The constitution of capraric acid.—**A. Franke** and **A. Kroupa**: Ring-contraction in the formation of inner ethers (oxides) from glycols (1, 5-oxido-dodecane from 1, 12-dodecanediol).—**A. Franke** and **A. Kroupa**: The preparation of α-alkyl-pimelinic acids from 1, 5-oxidodecane and 1, 5 oxido-dodecane. —**A. Haas**: (1) The mean mass-density of the universe. (2) The possible connexion between cosmic and physical constants.—**G. Nöbeling**: A fixed point theorem for curves connected *im Kleinen*.—**G. Nöbeling**: Universal curves of finite order.—**A. Wald**: Axiomatics of the concept 'between' in metrical spaces.—**K. Strubecker**: Helical lines in elliptical space.—**I Leng**: The question of photographic activity of metals after exposure to sunlight. The author did not succeed in getting results reported by others. **H. Brell**: The question of the linearity of the Lorentz transformation.

WASHINGTON, D.C.

National Academy of Sciences (*Proc.*, Vol. 16, No. 8, Aug. 15).—**G. A. Miller**: Groups which are decomposable into two non-invariant cyclic subgroups.—**Solomon Lefschetz** and **William W. Flexner**: On the duality theorems for the Betti numbers of topological manifolds.—**A. H. Sturtevant** and **T. Dobzhansky**: Reciprocal translocations in *Drosophila* and their bearing on *Œnothera* cytology and genetics. The suggestion that chromosome rings result from exchanges of ends between non-homologous chromosomes seems to apply to *Drosophila*.—**T. Elliot Weier**: Notes on the plastid and other cytoplasmic bodies during sporogenesis and spermatogenesis in *Polytrichum commune*. Previous to gametogenesis, the plastid assumes a form closely resembling a Golgi body.—**J. B. Conant** and **W. G. Humphrey**: The nature of the prosthetic group in *Limulus* hæmocyanin. A black material is obtained which contains copper and seems to be a complex salt of an amino acid containing sulphur.—**Lynn H. Dawsey**: The photochemical dissociation of nitrogen peroxide. Absorption spectra of nitrogen dioxide and tetroxide have been photographed at room temperature and at the temperature of liquid air. Primary photochemical decomposition of the mixture is due to the tetroxide and the threshold is at about 3800 A.—**J. B. Conant** and **F. H. Crawford**: The study of absorption spectra of organic compounds at liquid air temperatures. Absorption bands of porphyrins and similar coloured organic substances are resolved into finer lines at liquid air temperature.—**H. J. Schumacher**: A correction to "The Decomposition of Nitrogen Pentoxide at Low Pressures".

FRIDAY, OCTOBER 31.

INSTITUTION OF ELECTRICAL ENGINEERS (West Wales (Swansea) Sub-Centre) (at Corporation Electricity Showrooms, Swansea), at 6.—Sir A. Whitten Brown: Chairman's Address.

INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section), at 6.15.—H. T. Young: Is the Engineer of To-day making the Best Use of his Opportunities in Electrical Development in this Country?

INSTITUTION OF CHEMICAL ENGINEERS (at Institution of Civil Engineers), at 6.30.—Prof. W. A. Bone: High-Pressure Reactions (Lecture).

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemical Section), at 7.

SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section) (at St. Enoch Station Hotel, Glasgow), at 7.30. Dr. S. Miall: Editorial Notes on the Journal of the Society.

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7.30.—E. T. Westbury: The Two-stroke Engine.

GEOLOGISTS' ASSOCIATION (in Great Hall, University College), at 7.30.—Annual Conversazione.

INSTITUTE OF BREWING (at South-Western Hotel, Southampton).—A. Hadley: Some Aspects of Bottling.—H. L. Hind: Some Aspects of the Research Work.

IMPERIAL COLLEGE CHEMICAL SOCIETY (in Main Chemistry Lecture Theatre, Royal College of Science).—Prof. J. F. Thorpe: The Life and Work of W. H. Perkin, Junr.

MEDICAL SOCIETY OF LONDON.—Sir Almroth Wright and others: Discussion on The Prophylactic and Therapeutic Values of Vaccines.

INSTITUTE OF CHEMISTRY (Birmingham and Midlands Section) (at Grand Hotel, Birmingham).—R. B. Pilcher and others: Discussion on Co-operation.

MONDAY, NOVEMBER 3.

ROYAL SOCIETY OF EDINBURGH, at 4.30.—Dr. P. Eggleton: On Recent Work in the Biochemistry of Muscle.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Meeting.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—D. H. Patey: Demonstration of Specimens illustrating the Pathological Conditions of the Salivary Glands.

SOCIETY OF ENGINEERS (at Geological Society), at 6.—H. B. Millard: The Measurement of Water.

INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (at University, Liverpool), at 7.—H. A. Humphrey, D. M. Buist, and J. W. Bansall: The Steam and Electric Power Plant of Imperial Chemical Industries, Ltd., at Billingham.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—Prof. F. J. M. Stratton: Solar Eclipse Photography.

INSTITUTION OF AUTOMOBILE ENGINEERS (Glasgow Centre) (at Institution of Engineers and Shipbuilders, Glasgow), at 7.30.—Sir Herbert Austin: The Future Trend of Automobile Design (Presidential Address).

HUDDERSFIELD TEXTILE SOCIETY (at Technical College), at 7.30.—B. G. B. Slocombe: The Properties and Uses of Celanese.
SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Burlington House), at 8.—Prof. F. J. Spencer: Magnetic Susceptibility as a Means of Investigating Chemical Properties.—Dr. R. C. Farmer: The Mechanism of the Formation of Cellulose Nitrate and Other Nitric Esters
INSTITUTION OF ELECTRICAL ENGINEERS (Western Centre) (at Cardiff).

TUESDAY, NOVEMBER 4.

ROYAL SOCIETY OF MEDICINE (Orthopædics Section), at 5.—J. Verrall: Some Amputation Problems (Presidential Address).
ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. W. E. Hume: Paroxysmal Tachycardia (Bradshaw Lecture).
ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Dr. C. D. Ellis: New Aspects of Radioactivity (1).
MINERALOGICAL SOCIETY (Anniversary Meeting), at 5.30.—A. Russell: An Account of British Mineral Collectors in the 17th, 18th, and 19th Centuries.—M. H. Hey: Cupriferous Melanterite from the Skouriotissa Mine, Cyprus.—Dr. C. E. Tilley: (*a*) The Dolerite chalk Contact-zone of Scawt Hill, Co. Antrim; (*b*) The Production of Basic Alkali-rocks by the Assimilation of Limestone by Basaltic Magma: with Chemical Analyses by Dr. H. F. Harwood.—Dr. F. Smithson: A Simple Method of Observing the Magnetic Properties of Mineral Grains.
ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—W. B. Cotton: Exhibition of Ears and Molars of an African Elephant.—Secretary: Exhibition of Photographs of Elephants taken by Mr. M. A. Wetherall in the Belgian Congo.—J. R. Norman: Exhibition of Photographs of a Living Shark with a Remora attached.—D. Aubertin, A. E. Ellis, and G. C. Robson: The Natural History and Variation of the Pointed Snail, *Cochlicella acuta*.—B. J. Marples: The Proportions of Birds' Wings and their Changes during Development.—A. G. Lowndes: On Entomostraca from the New Hebrides collected by Dr. J. R. Baker.—H. W. Parker: A Collection of Frogs from Portuguese East Africa.
INSTITUTION OF CIVIL ENGINEERS, at 6.—Sir George William Humphreys: Presidential Address.
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—The Oleobrom Process.
SOCIETY OF CHEMICAL INDUSTRY (Nottingham Section) (at University College, Nottingham), at 7.30.—Dr. R. H. Pickard: Some Applications of Chemistry and Physics to the Examination of Hosiery Yarns.
INSTITUTE OF METALS (North-East Coast Local Section) (in Armstrong College, Newcastle-upon-Tyne), at 7.30.—S. L. Archbutt: Gases in Metals.

WEDNESDAY, NOVEMBER 5.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.
INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—C. E. Rickard: Chairman's Inaugural Address.
LIVERPOOL ENGINEERING SOCIETY (at 9 The Temple, Liverpool), at 6.30.—C. H. Faris: The Application of Electro-deposited Metals to Marine Engineering.
INSTITUTION OF HEATING AND VENTILATING ENGINEERS (at 29 Hart Street, W.C.1), at 7.—T. G. N. Haldane: The Operation of the Heat Pump and its Possible Application to Heating Problems, particularly Swimming Bath Heating
SOCIETY OF GLASS TECHNOLOGY (London Section) (at Holophane, Ltd., Elverton Street, S.W.1), at 7.30.—Discussion on The Etching of Glass:—Dr. S. English: Introductory Remarks.—E. A. Coad-Pryor: Etching of Bottles.—A. L. Marden: Etching of Lamp Bulbs.—E. Jacobs: Etching of Scientific Glassware.
SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society), at 8.—P. Arup: The Analysis and Composition of Vegetable Parchment used for Packing Dairy Products.—Dr. G. M. Moir: The Determination of the Milk Proteins.—Dr. S. G. Clarke: The Lead Reduction Method for the Volumetric Determination of Tin, and the Interference of Copper and Antimony.—W. J. Agnew: A New Method for Determining Traces of Chromium in Steel.
ROYAL SOCIETY OF ARTS, at 8.30.—Sir Edward Gait: Britain's Record in India (Inaugural Address).
ROYAL SOCIETY OF MEDICINE (Surgery Section), at 8.30.—C. H. Fagge: Presidential Address.
ROYAL MICROSCOPICAL SOCIETY (Biological Section) (at B.M.A. House, Tavistock Square, W.C.).

THURSDAY, NOVEMBER 6.

ELECTRICAL ASSOCIATION FOR WOMEN (at 15 Savoy Street, W.C.2), at 3.—Miss Beatrice Irwin: The New Art of Illumination.
ROYAL SOCIETY, at 4.30.—Prof. W. A. Bone and S. G. Hill: The Slow Combustion of Ethane.—Prof. A. M. Tyndall and C. F. Powell: The Mobility of Ions in Pure Gas.—A. Fage and W. M. Falkner: An Experimental Determination of the Intensity of Friction on the Surface of an Aerofoil.
ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. G. E. Gask: Vicary's Predecessors (Thomas Vicary Lecture).
IMPERIAL COLLEGE CHEMICAL SOCIETY (in Main Chemistry Lecture Theatre, Royal College of Science), at 5.10.—Dr. F. W. Aston: Mass Spectra and Packing Fractions (Lecture).
ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Prof. J. B. S. Haldane: The Physiology of Water (1).
INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—D. B. Hoseason: The Cooling of Electrical Machines.
INSTITUTION OF AUTOMOBILE ENGINEERS (Bristol Centre) (at Merchant Venturers' Technical College, Bristol), at 7.—J. Bradley and S. A. Wood: Some Experiments on the Factors affecting the Motion of a Four-wheeled Vehicle when some of its Wheels are locked.—J. Bradley and R. F. Allen: Factors affecting the Behaviour of Rubber Tyred Wheels on Road Surfaces.—A. H. Girling: A New Automobile Braking System.
SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (jointly with Manchester Sections of the Manchester Literary and Philosophical Society, British Association of Chemists, Institute of Chemistry, Institute of Fuel, Institution of the Rubber Industry, Oil and Colour Chemists' Association, Society of Dyers and Colourists, and Institution of Electrical Engineers) (at College of Technology, Manchester), at 7.—Sir William B. Hardy: Paper.
INSTITUTION OF ELECTRICAL ENGINEERS (North-Western Centre) (jointly with North-Western Centre of Institution of Mechanical Engineers) (at College of Technology, Manchester), at 7.—K. Baumann: Some Considerations in the Future Development of the Steam Cycle.
SOCIETY OF CHEMICAL INDUSTRY (Bristol Section) (at Bristol University), at 7.30.—R. F. Taylor: Glass and Glass Making, with Reference to Special Glasses.
ROYAL SOCIETY OF MEDICINE (Tropical Diseases Section), at 8.—Dr. E. C. Smith: Cultivation of the Spirochætes associated with Tropical Ulcer.
TEXTILE INSTITUTE (Irish Section) (at Belfast).—A. J. Hall: Properties of Artificial Silk as affecting Industrial Uses.

FRIDAY, NOVEMBER 7.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.—Sir T. Vijayaraghavacharyar: The Work of the Imperial Council of Agricultural Research.
ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 5.—Dr. E. Sheehan: Cinematograph Demonstration.—Dr. Chevalier Jackson and others: Discussion on Precancerous Conditions of the Larynx.
PHYSICAL SOCIETY (at Imperial College of Science and Technology), at 5.—Dr. W. N. Bond: Turbulent Flow through Tubes.—J. S. Rogers: The Photographic Effects of Gamma-Rays.—J. S. Badami: The Spectrum of Trebly Ionised Cerium (Ce IV).—Prof. S. Chapman: The Absorption and Dissociative or Ionising Effect of Monochromatic Radiation in an Atmosphere on a Rotating Earth.
ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Demonstration of Specimens of Surgical Interest recently added to the Museum of the Royal College of Surgeons.
INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Prof. J. W. Gregory: The Machinery of the Earth (Thomas Hawksley Lecture)
NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle-upon-Tyne), at 6.—R. W. Allen: Feed-Water Systems for Steam Installations
INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7.—E. Fawssett: Chairman's Inaugural Address
OIL AND COLOUR CHEMISTS' ASSOCIATION (Manchester Section, jointly with other Manchester Scientific Societies) (at Milton Hall, Manchester), at 7.
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group), at 7.—Informal Meeting.
SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (jointly with Institute of Chemistry, South Wales Section) (at Thomas' Café, Swansea), at 7.30.—A. Stuart: The Study of Crystals with Special Reference to Chemistry.
JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7.30.—H. Marryat: Luminous Electric Tubes (Neon, Helium)

SATURDAY, NOVEMBER 8.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—A. Hamilton Smith: Some Recent Archæological Work in Italy (1).

PUBLIC LECTURES.

SATURDAY, NOVEMBER 1.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—D. Martin Roberts: London in the Stuart Age.

TUESDAY, NOVEMBER 4.

KING'S COLLEGE, LONDON, at 11 A.M.—S. P. Turin: The Economic Geography of U.S.S.R.: Russian Farming and Agriculture.
UNIVERSITY COLLEGE, at 5.30.—Miss M. A. Murray: Egyptian Statues.
UNIVERSITY OF CAMBRIDGE, at 5.30.—Sir James Jeans: The Mysterious Universe (Rede Lecture).
MEMORIAL HALL (Farringdon Street).—Sir George Newman: How England learned to control Disease.

WEDNESDAY, NOVEMBER 5.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Prof. S. L. Cummins: The Prevention of Tuberculosis.
UNIVERSITY COLLEGE, LONDON, at 5.30.—I. C. Gröndahl: Norway, the Land and the People. (Succeeding Lectures on Nov. 12 and 19.)
LONDON SCHOOL OF ECONOMICS AND POLITICAL SCIENCE, at 6.—Dr. M. Culpin: Modern Views of Nervous Troubles. (Succeeding Lectures on Nov. 12 and 19.)

THURSDAY, NOVEMBER 6.

KING'S COLLEGE, LONDON, at 3.—C. J. Gadd: Babylonian Religion.
ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Dr. Marie C. Stopes: History and Theory of Contraceptive Technique.
ROYAL SOCIETY OF MEDICINE (in Barnes Hall), at 5.—V. E. Negus: Some Observations on Semon's Law (Semon Lecture).
BEDFORD COLLEGE FOR WOMEN, at 5.15.—Dr. H. Clay: Economic Responsibility.
BRITISH MEDICAL ASSOCIATION (in Hastings Hall, Tavistock Square), at 5.15.—Dr. M. Ray: The Treatment of Rheumatism (Chadwick Lecture).
MEMORIAL HALL (Farringdon Street).—Sir George Newman: Health Problems of the Modern Period.

SATURDAY, NOVEMBER 8.

MATHEMATICAL ASSOCIATION (at Bedford College for Women), at 3.—A. Russell: Some Methods of Lightning Calculation.
HORNIMAN MUSEUM (Forest Hill), at 3.30.—M. A. Phillips: Animal Childhood.

CONGRESS.

NOVEMBER 1 AND 2.

INSTITUTE OF SOCIOLOGY (at Imperial Institute).—Lectures and Discussions on Sociological and Survey Topics.

Scientific Workers in Government Employment.

THE Report of the Committee appointed by the Treasury in May 1929 "to examine the functions and organisation" of certain specified scientific establishments in the Government Service, and "to report on the method of recruitment and conditions of service of the civilian scientific and technical officers employed therein", has now been published (H.M. Stationery Office, 9*d*. net). The specified departments were :

(*a*) The research and experimental establishments under the Admiralty, War Office, Air Ministry, and Department of Scientific and Industrial Research ; (*b*) the Department of the Government Chemist and the establishments under the Admiralty and War Office concerned with chemical analyses ; and (*c*) the Meteorological Office.

The Report contains a number of important recommendations, and although it introduces differentiations which will inevitably give rise to dissatisfaction among certain sections of the staffs affected, its proposals, if put fully into effect, represent on the whole a great step forward in the direction of both higher status and fuller economic recognition for the scientific worker in Government employment.

The Committee, over which Sir Harold Carpenter presided, was a strong one and included, in addition to an administrative element drawn from the Treasury and War Office, Sir Robert Robertson, the Government Chemist ; Dr. F. E. Smith, Secretary of the Department of Scientific and Industrial Research ; Mr. H. T. Tizard, his predecessor in office and now Rector of the Imperial College ; and Mr. H. E. Wimperis, Director of Scientific Research at the Air Ministry. Evidence was received from the heads of all the larger scientific establishments, while the views of the staffs concerned were represented to the Committee by the Institution of Professional Civil Servants.

The examination of radical proposals for a complete change in the relationships of the scientific departments would appear to have fallen well within the terms of reference. The Committee, however, showed the better part of valour by the ingenious gloss that, as the respective functions of the establishments under consideration had 'recently' (actually in 1928) been set out in considerable detail in the Report of the Research Co-ordination Sub-Committee of the Committee of Civil Research, they had "assumed the first part of our terms of reference to be an instruction, not to

criticise and report on those functions, but to take note of them as the basis of our investigation into the conditions of service of the staffs employed ". Accordingly, " we have considered it unnecessary for us to report, for example, on a proposal (admittedly not unanimous) made to us by the Institution of Professional Civil Servants, for a unified State Scientific Service in the form of a Ministry of Science ".

Although the idea of closer unity of which a Ministry of Science is but the extreme form of organisation did not command the unanimous support of both wings of the Institution's membership, it will be a disappointment to all concerned that such an authoritative Committee should not have given a definite lead, or at least some guidance for the direction of the future development of the scientific services. The Committee has, however, made a series of proposals, following in principle very closely those submitted to the Committee by the Institution and endorsed by the Association of Scientific Workers, which will achieve a greater measure of uniformity in the conditions of service of the staffs concerned, and so pave the way to a more harmonious and progressive development of the scientific services than is at present practicable with the existing departmental structure.

As regards the contention that the present salaries and financial prospects of the scientific staffs in Government service are shown to be generally inadequate by the difficulty of recruiting and retaining officers of the requisite standard, the Report states that " it is open to question whether the State Services are at present attracting a fair proportion of the best recruits. In any case, we think that the present supply is neither so large nor so good as it might be if the conditions of employment were made more attractive." The Report goes on to remark that " the fact remains that the State has to compete with private industry as well as with the universities for the services of research workers, and we are clear that some steps must be taken to make that competition more effective ".

The Committee's proposals for an improved and unified system of salary scales are subject, however, to certain important reservations. It insists—and here it had the full support of the staff organisations—not only that the standard of recruitment must be high, but also that duties must be strictly graded so as to ensure that scientific officers " are always employed either on investigations which definitely require originality of outlook and execution, or on work which, though not demanding exceptional originality, does require wide knowledge and special experience ". Work of an " ancillary character " must, it is urged, be devolved upon a class of ' technical assistants ' corresponding in principle with such existing classes as those of ' observer ' and ' technical assistant ' in the Department of Scientific and Industrial Research and ' test assistant ' at the Royal Aircraft Establishment, for whom improved salary scales and prospects are also recommended.

The new grades and salary scales do not go beyond the existing rank of Principal Scientific Officer at the National Physical Laboratory or its equivalent. Of this senior grade it is stated that the qualifications will normally include both scientific attainment and power to organise and direct research: but the latter is not regarded as essential, and the important recommendation is made that it should be possible for a research officer to reach this grade solely on his merits as an individual investigator. The Committee states that it looks forward to " the Government research establishments being ultimately so organised and recruited that every research officer will be able to reach this grade before retirement, provided only that his proved capacity on appointment is followed by normal development during service ". This departure from civil service practice is an innovation which will be warmly approved by those who feel that the principles and methods of promotion normally applied in the civil service among the non-technical staffs are somewhat too rigid in their application to those engaged in creative scientific work.

While the Committee's grading proposals are based on the conception of uniformity, they retain the present distinctions between ' research ' staffs on one hand and ' technical development ' and chemical staffs on the other hand, as regards provision for superannuation. For the former, the continuance of the Federated Universities Superannuation Scheme is proposed, and for the latter the normal superannuation provision for established civil servants made by the Superannuation Acts. Taking this line of cleavage, the Committee differentiates markedly between the careers to be offered on the respective sides, notably in the earlier stages of service. In the case of staffs under the ' F.U.S.S.', the new entrant, who will normally be a university graduate with first or second class honours, will be appointed as a ' junior scientific officer ' on a scale of £200-15-260 (basic). When he reaches his maximum of £260 steps are to be taken " to assess his capacity for

research work ". His record will be reviewed by a selection board, which will keep in mind that the next grade of 'scientific officer' "should include on the one hand officers who must be specially qualified to undertake research work, and on the other hand those who will be engaged on work which although of a responsible nature and best undertaken by officers recruited after graduation at a university, requires scientific experience rather than special aptitude for research ". If he is found to be qualified for the duties of a 'scientific officer', he will be promoted to that grade, the basic scale for which will be £300-550; while if he is recommended as exceptionally qualified to undertake research, he may enter the scale at £350 (basic). It is further recommended that a junior scientific officer "who after being two years at his maximum, has not been recommended as suitable for appointment as scientific officer, should be required to leave his department, unless he can be appointed to a vacancy in one of the assistant grades ". This process of selection for retention in the service as a scientific officer and the power of allowing the research worker of exceptional promise to jump to £350 (basic) are extremely important suggestions and will do much to render more attractive the research side of the scientific services.

Unfortunately, however, the counterparts of these proposals for the junior grades in the 'technical' and chemical establishments are not identical, with the result that although some existing anomalies are removed among the F.U.S.S. staffs, new differentiations will be introduced in the Air Ministry and Admiralty as between the 'scientific' and 'technical' pools, the members of which are at present uniformly graded. The differentiations will, however, on balance involve a wide measure of unification; for the existing welter of grades and salaries will be replaced by two simple hierarchies, which will be identical in the case of senior officers.

The claims made on behalf of the staffs within the Committee's terms of reference involved complete unification and a commencing basic salary of £250 after a suitable period of probation; and the suggestion that only "limited" prospects should be offered to the technical and chemical staffs of going beyond £450 (basic) will not only give rise to serious dissatisfaction, but also go far to nullify the Committee's efforts to make the State scientific services more attractive. So far as the technical and chemical departments are concerned, it will still be the case that a more lucrative career will be open to the secondary school boy of scientific leanings if he enters the civil service in a non-technical capacity, through, say, the Executive Class examination at the age of eighteen years, for success in that examination will ensure him a clear run through to a salary of £400 (basic) without special efficiency bars and without expensive training, and on first promotion he will be assured of a jump to a scale rising from £400 to £500 basic.

While the Committee makes no specific recommendations with regard to the posts graded higher than principal scientific officer which carry administrative as well as scientific responsibilities, it is pointed out that it is obvious that if the other recommendations are accepted, the position of senior officers will call for review, and that the salaries attaching to many of these posts will have to be increased. As some members of the Committee were in the category in question, it is suggested that a small *ad hoc* committee should be appointed to consider the higher posts. In this connexion it is pointed out that those members of the Committee who have had direct responsibility for recruitment to scientific research staffs have found the inadequacy of the prospects offered by the higher posts a serious obstacle.

On a superficial examination, the Report would appear to be primarily concerned with economic questions affecting the conditions of employment of the State scientific worker, but when the Report is read in conjunction with a knowledge of the diversity of minutely differentiated salary scales and general conditions of employment that obtains in the scientific departments, it will be seen that it represents a very important stage in the development of those services. The recognition of the fact that the scientific workers in State employment are as a class performing a distinctive service will be more readily achieved now that, like other distinctive classes of civil servants, their conditions of employment have been closely assimilated. Moreover, by its insistence upon the need for a departure from normal service practice in the case of the socially valuable but often unrecognised gifted individual research worker without administrative talents, the Committee has made a break with precedent which must have important results. While scientific workers in Government employment as a whole will deprecate the discrimination against technical and chemical staffs, they will, we are sure, be grateful for the care which has obviously been devoted to examining their conditions of employment, and it is to be hoped that the Government will refrain from devising the familiar official excuses for pigeon-holing the Report.

The Human Blood Groups.

Blood Grouping in Relation to Clinical and Legal Medicine. By Prof. Laurence H. Snyder. Pp. xi + 153 + 5 plates. (London: Baillière, Tindall and Cox, 1929.) 22*s.* 6*d.* net.

A PECULIAR value is lent to this book by the fact that its author is not a medical man and that his horizon is therefore not overclouded by the medical applications of his subject. It cannot be said that it has not a certain medical tinge, for Prof. Snyder states with modest pride that he has been concerned in a number of operations for the transfusion of blood; moreover, he has not been able to avoid an excursus into the history of blood transfusion which is interesting but not really germane to his subject. None the less, Prof. Snyder is primarily a biologist and thoroughly competent to deal with the relation of the blood groups to human biology, and this is where their main interest lies.

The best chapters in Prof. Snyder's book are those on Mendelian inheritance, the heredity of the blood groups, the blood groups in animals, and their racial distribution. It is a great pity that the two latter were not considerably extended; very little of the knowledge on these subjects has as yet been collected in book form. The chapter on the technique of blood transfusion cannot be recommended to those about to embark upon the procedure for the first time; it contains descriptions of the divers more or less elaborate pieces of apparatus which have been invented for this purpose by those having a passion for making the simple thing difficult, but fails to lay stress on the fact that all that is actually required in the way of special apparatus is a funnel, tubing and cannula, and an enamelled pint pot, such as is to be found in every nursery and most kitchens. It is, moreover, difficult to understand why Prof. Snyder does not regard direct matching of blood, without grouping, as a satisfactory means of selecting a donor.

The demonstration of the fact that the bloods of all human beings is not identical, but that they fall into four well-defined groups, is one of the most striking of the more recent advances in human biology; the facts of the case are not yet widely known, though much of the knowledge has been available for the past twenty years, and Mr. Snyder has performed a good service in crystallising the present state of knowledge in book form. The credit for the discovery of the groups must rest with Landsteiner; before his time various observers had reported the agglutination of the red cells of one individual by the serum or plasma of another, but up to then such occurrences had been regarded as pathological. Landsteiner in 1900 showed that the serum or plasma of certain normal individuals would agglutinate the red cells of other normal persons, and that this phenomenon was no indication of disturbed health; in 1909 he showed that on the basis of this reaction it was possible to distinguish at least four types of blood. The same thing was shown more or less independently and almost synchronously by Moss in America and by Jansky in Europe; these authors applied numbers to the four groups, but unfortunately they used different numbers for the same things, and thus laid the foundations of a confusion which exists to the present day. When an author speaks of Groups I. or IV. it is even now impossible to know to what he refers unless he appends the name of one of these observers. Landsteiner in his earlier work forecast the importance of the groups both in regard to the transfusion of blood and to legal medicine, but in spite of this, for many years his work was scarcely regarded.

In 1910 von Dungern and Hirzfeld made an intensive study of the inheritance of the groups in a series of families and showed that the observed facts were explicable on the postulation of two dominants presenting the agglutinable substance, which were resident in the red corpuscles, and were referred to as *A* and *B*, and two recessives represented by the corresponding agglutinins and resident in the plasma. Though this hypothesis has lately been the subject of important modification at the hands of Bernstein, the agglutinable factors, or, as it is now the abhorrent but ineradicable custom to describe them, the agglutinogens *A* and *B* still hold the field, and although Prof. Snyder is rather timorous about committing himself on this point, there is every reason that the numerical nomenclature of the groups should now be dispensed with and that they should hereafter be known by their agglutinogen content as *AB*, *A*, *B*, and O.

It is true that various workers have from time to time produced evidence purporting to demonstrate the existence of agglutinogens other than *A* and *B*. The most portentously long and detailed papers are those of Guthrie and Huck. Prof. Snyder adopts a cautious, not to say timid, attitude in regard to the possible existence of agglutinogens other than *A* and *B*, but it is now fairly evident that the whole structure of the groups is explicable on the postulation of these two only, and that observations reported as demonstrating the exist-

ence of others have depended upon errors of one sort and another, and more particularly failure to recognise that there are differences both in the titre and adsorptive power of agglutinogens and also in the titre of agglutinins in different bloods.

The history of the subject so far as it has gone offers an excellent demonstration of the weakness inherent in the experimental method. The original discovery of the groups and the elucidation of their structure were brought about by sound induction from observed facts. Further experimental work in the hands of many observers revealed what appeared to be exceptions to the general law laid down as a result of the work of Landsteiner, von Dungern and Hirzfeld, and others, and, modern science being firmly bound to the chariot of the experimental method, such observations were accepted at their face value. But the experimental method has its weaknesses. Next to the original discovery of the groups and of their structure, the greatest triumph in this field has been the enunciation by Bernstein of his hypothesis as to their inheritance. It does not appear that this worker performed a single experiment; he did, however, survey with care the data as to the distribution of the groups in various human races, and by the application of mathematical methods was able to show that this distribution could indeed be accounted for by the postulation of the agglutinogens *A* and *B*, but that they must be inherited, not as von Dungern and Hirzfeld had supposed, but as two of three allelomorphs, the third being their absence or 0. Further work has provided no significant exceptions to what may now be described as Bernstein's law.

In the face of the conformity of the known facts to Bernstein's law, it is difficult to believe in the existence of agglutinogens other than *A* and *B*, and in this respect and in spite of a great deal of experimental work and the expenditure of much paper and ink, the situation remains where it was twenty years ago. The whole episode serves to point the remarks of the prelate who at a recent meeting of the British Association pleaded for a seven years' truce of God to experimental work and a consideration of the data already accumulated.

The establishment and general acceptance of Bernstein's law is of considerable practical importance. On the original assumption of von Dungern and Hirzfeld, it is obvious that the appearance of the agglutinogens *A* or *B* in the blood of a child when absent from that of the alleged parents is conclusive proof that the parentage is not as supposed; Bernstein's law limits the possibilities even further; it follows from it that matings involving one *AB* parent cannot result in 0 offspring. It is true that *AB* is a rare group, but this narrowing of the field of possible inheritance is of the greatest importance in legal medicine. In Germany, Russia, and several other European countries, evidence based upon the blood groups is freely admitted in forensic proceedings both civil and criminal, but in the courts of Great Britain natural laws have yet to establish their validity. When it comes, the spectacle of the British legal mind wrestling with the laws of Nature will be full of interest and instruction.

In full-blooded American Indians, Prof. Snyder found more than 90 per cent Group 0 individuals, and his observations go far to support the view that this is the original constitution of the blood of the human race; the agglutinogens *A* and *B* seem to have appeared as mutations, the *A* factor somewhere in western Europe, the *B* somewhere in central Asia. The author wisely points out that the anthropological information to be gained from a study of group distribution is limited, and that up to the moment it fails to throw any light on the question of the single, double, or multiple origin of the human race.

S. C. DYKE.

Problems of Asiatic Geology.

The Structure of Asia. Edited by Prof. J. W. Gregory. (Methuen's Geological Series.) Pp. xi + 227 + 23 plates. (London: Methuen and Co., Ltd., 1929.) 15*s.* net.

THIS book contains a series of contributions to an international discussion, held at the British Association meeting in Glasgow in 1928, on problems of Asiatic geology.

Since the publication of the third volume of "Das Antlitz der Erde", more than a quarter of a century ago, wherein Eduard Suess gave his classic account of the geological structure of Asia, increasing evidence has been accumulating that many of his views on the origin and classification of the Asiatic mountain ranges are in need of modification. Thus, his representation of the structure of the eastern coast as bounded by a series of folded mountain arcs continuous with the Himalayan ranges has for many years been abandoned in view of von Richthofen's description of the great fault-blocks which constitute the dominant tectonic feature of that area.

There must, indeed, be many geologists who have found it hard to form an unbiased opinion of, for example, the relationship of the Altaid and Himalayan mountain systems when confronted with the

fundamentally different ideas expressed by Suess and Argand; and for the solution of this and other problems they will welcome the opportunity of obtaining the views of recognised authorities on the subject which is afforded by the publication of the volume now before us.

The introductory chapter by the editor, Prof. J. W. Gregory, which is replete with first-hand information obtained during his own travels in Asia, not only gives a clear and concise summary of much that is contained in the subsequent chapters, but also affords a valuable guide to the discussion of the more controversial questions.

Prof. F. E. Suess contributes an interesting account of modern views regarding the region of the Variscan horsts of Europe, in which he stresses the importance of studying 'intrusion tectonics' rather than mere trend-lines in determining the age of mountain chains and their structural connexions. From a consideration of the crystalline schists of the European Altaids, which, in opposition to the generally accepted view, he regards as having been formed by late Palæozoic granitic intrusions, he abandons his father's theories as to the pre-Palæozoic age of the crystalline schists of the nucleus of Asia.

A wealth of new information, now published for the first time, is contained in the chapter on the tectonics of the Iranian ranges by Dr. H. de Bockh and his colleagues on the staff of the Anglo-Persian Oil Co., Ltd. Their discovery and description of the great Iranian geosyncline appears to be in direct opposition to the view expressed by Argand that the movement of Africa north-eastwards against Asia continued as late as Miocene times, and their account of the strong Pliocene folding of south-west Persia is entirely inconsistent with the conception of the opening of the Mediterranean rift at that time.

It may be suggested that the cost of publication could have been materially lessened without in any way impairing the value of the work if this contribution had been reduced by the omission of much of the detailed evidence on which the conclusions are based. It is, moreover, difficult to see how the profile sections across the Andes of Colombia and Venezuela are germane to the present discussion.

Prof. D. I. Mushketov, in an interesting account of the tectonic features of eastern Turkestan, shows that north of the Pamir there was a northward direction of folding in the Kainozoic era as opposed to the general southward movement of the Himalayan ranges.

The structural evolution of the eastern part of the Asiatic continent is described by Prof. G. S. Barbour with the aid of a series of palæographical maps redrawn from those of Dr. A. W. Grabau, and an account of the structural features of the 'Old-rock floor' of the Gobi region, the result of personal observations made during the Central Asiatic expeditions of the American Museum of Natural History, is contributed by Prof. Berkey of Columbia University. Five periods of orogenic movement are described, each of which was accompanied by volcanism. Copious references throughout the volume furnish a valuable bibliography of the geology of Asia

Bushman Art in South-West Africa.

Bushman Art: Rock Paintings of South-West Africa, based on the Photographic Material collected by Reinhard Maack. By Hugo Obermaier and Herbert Kühn. Pp. xii + 70 + 39 plates. (London: Oxford University Press, 1930.) 84s. net.

In a people's art is of particular importance. When objects made for purely utilitarian purposes, such as tools and weapons, are alone available for comparison, the sceptic can often argue that similar implements made by two peoples in widely separated areas are merely the results of similar needs engendered by somewhat similar conditions of life, and that therefore no cultural relationship between the peoples concerned need be postulated. When however, the artistic productions of two such widely separated peoples manifest striking similarities of style and technique, it becomes difficult to deny some definite cultural connexion. The study of primitive art groups, both modern and prehistoric, in different regions of the world, is thus of vital importance in the elucidation of human history.

The volume under review presents the anthropologist with an account of a number of paintings found on the walls of rock-shelters and on boulders in what was formerly German South-West Africa. The original investigations were carried out some time ago by a German resident, Mr. Reinhard Maack, who has since handed over his photographs and copies of the paintings to Dr. Obermaier of Madrid; and it must be said at once that he could not have confided his valuable material into more competent and distinguished hands. The resulting monograph which Dr. Obermaier has written in collaboration with Dr. Kühn of Cologne, the editor of the *Jahrbuch für prähistorische und ethnographische Kunst*, is of very great scientific importance—as, indeed, we should expect it to be,

considering the European reputations of its authors. The second and larger half of the book is occupied by thirty-nine plates, of which thirty-two are in colour, the earlier part being devoted to a description of the sites and a general account of the problems connected with Bushman art.

In the opening chapter some notes on the Bushmen themselves and their art are given, together with a brief summary of the succession of stone age cultures in South Africa. Chap. ii. is devoted to an account of the pictorial material collected by Reinhard Maack. Chap. iii. is entitled "The Spirit of Bushman Art", and therein is attempted a study of the minds of the artists as seen through their work. Chaps. iv., v., and vi. are concerned with the occurrence of more or less similar art groups in South Africa, eastern Spain, and elsewhere. The last chapter discusses the meaning and significance of Bushman art. A selected bibliography is appended at the end of most of the chapters. Chaps. i., ii., iv., and v. are from the pen of Dr. Obermaier, while Chaps. iii., vi., and vii. are contributed by Dr. Kühn.

The investigations in the field seem to have been confined almost solely to the paintings themselves; no proper excavation seems to have been attempted in the floors of the painted sites, and although stone industries are sometimes mentioned as being present, no description of the finds is given. This, perhaps, is to be regretted, as in Southern Rhodesia and the Union of South Africa various phases of the Bushman art are often associated with stone industries belonging to different cultures. Stone implements occur in the district (as, for example, near Swakopmund), and it would have been illuminating to know what sort of industries were made by these South-west African artists. Again, though superpositions of paintings are alluded to, reproductions or descriptions of them -which would, perhaps, have afforded us sequences of styles or techniques—do not seem to have been given by Mr. Maack.

None the less, this book constitutes the first careful study of Bushman art in this part of Africa. On examining the excellent reproductions in colour, the obvious similarity of some of these paintings to early Southern Rhodesian examples on one hand, and to more recent examples in the Union of South Africa on the other, is at once apparent. That all 'Bushman art' in South Africa was made at approximately the same time is out of the question. Many a century, probably indeed many a millennium, elapsed between the making of the first and last paintings. Nor is it at all certain that men of quite the same race were the authors of the early as well as the later examples. It would seem more probable that the whole corpus of Bushman art should be considered as part and parcel of the general artistic activity of Neanthropic man, the work of various migrations of Neanthropic peoples into South Africa—the last of these migrations having ushered in the Bushmen themselves. In the same way, the rock-shelter art of eastern Spain, which is so similar to the earlier series of Southern Rhodesian paintings while differing somewhat from the more typical Bushman art found nearer the Cape, is equally to be connected with this general artistic activity of Neanthropic man and therefore perforce related to the African art groups. With these theories Dr. Kühn seems to be in general agreement. Dr. Obermaier remains rather more conservative and would like to see them confirmed by the finding of skeletal remains demonstrating the racial similarity of the Spanish and African artists. Such finds will probably be made some day. In the meanwhile the conservative attitude is, of course, a sound one and Dr. Obermaier presents the whole case to the reader in a clear and unbiased manner.

Altogether the book makes a notable contribution to knowledge, is well translated from the German, excellently produced, and priced at a distressingly high figure. But one such monograph, containing as it does information of permanent value, is worth many volumes which merely set forth the theories temporarily held by their writers.

M. C. BURKITT.

Physical and Chemical Properties of Interfaces.

(1) *An Introduction to Surface Chemistry.* By Dr. E. K. Rideal. Second edition, revised and enlarged. Pp. ix + 459. (Cambridge: At the University Press, 1930.) 21*s.* net.

(2) *The Physics and Chemistry of Surfaces.* By Dr. N. K. Adam. Pp. x + 332. (Oxford: Clarendon Press; London: Oxford University Press, 1930.) 17*s.* 6*d.* net.

IN August 1918, after sending to the late Lord Rayleigh some reprints and expressing to him my regrets that he had not continued his extensive pioneering work on surface tension, I received a reply from which the following is quoted:

"As regards what you say as to my not following up my own work on surface tension, etc., I may confess that I was rather disappointed at the little attention I then received. Besides that, I was and am rather badly equipped for speculations on the

chemical side. There is one point which I do not find noticed by you or Devaux relating to what occurs when a very limited amount of oil is deposited on a large clean water surface. I do not think the spreading can stop just when the layer has become monomolecular. At this stage there would be considerable outward motion extending downward a certain distance, which must carry the spreading further. Finally the drop is larger than necessary, and its contraction is not resisted by any force.

I am,
Yours very truly,
RAYLEIGH."

Fortunately to-day there is no lack of interest in surface tension and the varied phenomena occurring at the interfaces between phases. A striking proof of this lies in the nearly simultaneous publication of two excellent books in English dealing with this subject, which is so largely the outgrowth of Rayleigh's observations and speculations. Both books are by men who have themselves for several years made very important contributions to our knowledge of surface properties.

Although both books treat of the physics and chemistry of surfaces, there are considerable differences in the subject matter and the methods of presentation. Rideal's book is a revised and much enlarged (35 per cent increase in size) second edition of his book of 1926. There are six chapters covering surface tensions of liquids and of solutions, insoluble films on liquids, liquid-liquid, liquid-solid, and gas-solid interfaces. Two chapters treat the electric potentials at interfaces, stability of suspensions and emulsions, and the last chapter deals with gels and hydrated colloids. There are good indexes of names and subjects, but a table of contents giving more than the titles of the chapters would be desirable.

An excellent discussion of the various experimental methods for the measurement of surface tension is included in the first chapter.

Adam's book also has nine chapters, arranged in somewhat less logical order. The opening chapter considers the elementary theory of the capillarity of liquids, emphasising the importance of molecular motions and interactions. The methods of measuring surface tensions are considered in the last chapter of the book.

The second chapter, of about 75 pages, is devoted to insoluble monomolecular films on water. This chapter constitutes a particularly valuable summary of the rapidly accumulating knowledge of the properties and structures of these films—knowledge which has resulted so largely from the efforts of Adam and his co-workers. There is a detailed description of the latest form of balance for measuring the surface pressures of films and of the precautions required in its use. Films are classified as gaseous, condensed, liquid expanded, and vapour expanded. The history of the development of these concepts is admirably treated. The evidences that the films are monomolecular and oriented on the surface are emphasised and properly evaluated. Fundamental concepts are often strikingly illustrated. For example, in justifying the use of surface pressure, we note the remarks (p. 30): "How far should we have progressed if, in the study of gases, the pressure exerted by a gas on its confining walls had been regarded as the difference between the strong tension of the clean vacuum outside the vessel and the contaminated vacuum within? The surface pressure is the tangible, physical force; the surface tension merely the mathematical equivalent of the free surface energy."

In a few other cases the reviewer cannot agree so completely with the explanations adopted. For example, he believes that too much stress is laid on the 'angle of tilt' of the molecules in a film. A more useful view is that in liquid films of such substances as the higher fatty acids, the hydrocarbon chains are arranged almost as irregularly as in any liquid phase, subject only to the requirement that one end of the molecule must remain in contact with the water. The reviewer cannot agree (p. 75) "that the heads tend to hold the molecules together, while the chains try to disrupt the film". When there are no heads, the film actually contracts into a single droplet, proving that it is the heads that cause the spreading.

The study of surfaces is interrupted in Chapter iii. in order "to review the information available as to the properties of molecules obtained from other sources", such as X-ray studies of organic crystals and liquids, and then in Chapter iv. thirty pages are devoted to surface films of soluble substances and adsorption. The next chapter deals with results of the measurements of surface tension. The whole consideration of the interesting relations of the surface tensions and the total surface energies of benzene substitution products is brushed aside with the statement (p. 151) that "it seems doubtful if the values of the total surface energy can be made to furnish information as to the orientation of the surface molecules"—a conclusion with which the reviewer wholly disagrees.

The properties of solid surfaces, the spreading of liquids on liquids and solids and lubrication are discussed in the next two chapters. A chapter of sixty pages deals with the structure and the chemical properties of solid surfaces and adsorbed films

on them. A discussion of heterogeneous chemical reactions occupies about ten pages, but the electrical properties of surfaces are not considered.

Although both books cover nominally the same subject matter, the differences in treatment and even in the choice of topics make it desirable for every student in this field to read both books. Rideal's book is more comprehensive and gives the better general survey, but Adam's book is unsurpassed in those fields in which he has specialised.

I. LANGMUIR.

Our Bookshelf.

L'Appareillage électrique : le petit appareillage, le gros appareillage basse tension, l'appareillage haute tension, tableaux de distribution, postes de transformations ruraux ; construction, applications. Par Louis Lagron. (Nouvelle Encyclopédie Électromécanique, No. 3.) Pp. 587. (Paris : Albert Blanchard, 1930.) 36 francs.

THIS is the third volume of a useful electromechanical encyclopædia. The author classifies electric apparatus into four groups. First, there is small apparatus, that is, apparatus for use at low voltages and that does not take a current greater than twenty-five amperes ; next he deals with large low voltage apparatus which takes currents greater than twenty-five amperes. The third class consists of high voltage apparatus, the pressure not exceeding 33,000 volts but the current being of any value. The fourth class consists of very high voltage apparatus, the pressure exceeding 33,000 volts. We learn that the French Minister of Public Works standardised the voltage of supply at 230 in July 1925. The pressure of supply of all work completed after that date is to be 115, 230, or 460 for direct current supply, and 115 or 230 for all systems of supply installed after that date. The frequency also is to be 50. Like England, however, it will take a long time before all the pressures of supply are standardised.

Tables are given of sparking distances, and amongst the constants given for insulating materials are their electric strengths. The formulæ given for fuses and for the heating of cables are only roughly approximate. The laws of the convection of heat from bodies cooling in air are now well known and more accurate formulæ could have been given. English engineers will be interested in the information given for wooden poles, cement poles, and lattice towers.

Cours de mécanique professé à l'École Polytechnique. Par Prof. Paul Painlevé. Tome I. Pp. vi + 664. (Paris: Gauthier-Villars et Cie, 1930.) 100 francs.

FOR many years now the underlying principles of mechanics have been the subject of critical revision. In an elementary treatment of these principles from the point of view of teaching, however, it is quite impossible to approach the subject except largely from the classical point of view, if not because of the essential difficulties of the relativistic outlook, at least because a knowledge of classical mechanics appears to be essential for a true understanding of relativity.

M. Paul Painlevé seems to have found time from his political activities to produce in this "Cours de mécanique" a complete treatment of the first stages of this subject, as they have been expounded by him in his course at the École Polytechnique between 1905 and 1924. The course bears all the marks of a thorough and careful teacher, and the consistent striving after rigorous presentation is typically French in its precision. The earlier part of the course covers most of the material which is normally dealt with in English colleges under the heading of "motion of a particle and of a system of particles", with astronomical applications to planets and comets. In the later part the author goes on to discuss Lagrange's equations, D'Alembert's principle and its various extensions, the equilibrium of strings, and the nature of frictional forces.

Although the field has been well traversed in English books, nowhere has it been so carefully developed and so logically knit together as in this classic by a world-famous teacher.

The Conclusions of Modern Science. Plainly told by Walter Grierson ("The Enquiring Layman"). (The Outline Library, No. 10.) Pp. xviii + 198. (London : George Newnes, Ltd., n.d.) 2*s*. 6*d*. net.

IN this little book, "The Enquiring Layman" has marshalled the majority of the most important facts and conceptions of modern science. A layman he might claim to be, yet he cannot be a real visitor to the subject of science. He shows a definitely intelligent attitude towards it and presents his findings in a distinctly palatable style.

Astronomy, natural philosophy, biology, and the other conventional branches of science receive consideration, yet the author—quite unconsciously perhaps—has performed one important feat in showing that this conventional subdivision of science is essentially artificial. Of all the subjects dealt with, the most abstract, man the interpreter, is probably the author's *pièce de résistance*.

It is evident that "The Enquiring Layman" is keenly interested in the subject, and he has presented it in such a manner as will infuse a similar interest into his readers.

Practical Plant Biochemistry. By Muriel Wheldale Onslow. Third edition. Pp. vii + 206. (Cambridge : At the University Press, 1929.) 12*s*. 6*d*. net.

MRS. ONSLOW'S book fills a decided gap in botanical literature. Since its first appearance, it has been considerably extended by a chapter on the plant acids, as well as by shorter sections on the derivatives of these bodies, waxes, essential oils, and also nucleic acid. Serious changes of form are scarcely possible in a text-book of this character, but an additional chapter, in many ways the most interesting in the book, has now been added on the possible interrelationships of the hexose sugars, the pentoses, and the pectic substances. The recent work on the oxidising systems of plants is also summarised in a convenient form.

Letters to the Editor.

A Relation between the Radial Velocities of Spiral Nebulæ and the Velocity of Dissolution of Matter.

ACCORDING to a fundamental formula of Einstein's cosmological theory of gravitation, the total mass of the universe, M, is connected with the radius of curvature of the universe, R, by the formula

$$(1)\quad M \quad {}_{2f}R.$$

In this equation c denotes the velocity of light and f the constant of gravitation.

If we regard the size of the universe as variable, and if we denote by a the 'disintegration constant' of matter and by v that 'cosmic velocity' which represents the differential coefficient of R with respect to time, we obtain from equation (1):

$$(2)\quad Ma = \frac{c^2\pi}{2f}v.$$

As is well known, a is equal to the mass equivalent of 2 ergs per gram-second in the case of the sun. The average value for all fixed stars undoubtedly agrees in order of magnitude with that value. Hence, approximately,

$$(3)\qquad \frac{4f}{\ }M \quad 1{\cdot}1 \times 10^{49}M.$$

If we insert for M, according to Hubble (*Astrophys. Jour.*, **64**, p. 369; 1926), $1{\cdot}8 \times 10^{57}$ gm., equation (3) yields for v a value of about 2×10^8 cm. or 2000 km. per second. This value agrees well with the magnitude of the velocity with which the farthest spiral nebulæ appear to recede from us.

Animal Husbandry.

THE term 'animal husbandry' is gradually becoming more employed by both administrators and scientists concerned with the live stock industry. That it is differently employed by different speakers is the apology for what follows.

The aim of the science of animal husbandry is the efficient production of farm live stock: it deals with the application of those basic sciences which affect the production and maturation of our farm live stock. The principal sciences from which it derives are genetics, nutrition, animal health, economics, and physiology, both reproductive and nutritional. These basal sciences seek to discern fundamental principles by the formation of hypotheses, which as evidence accumulates become theories, and eventually on final proof take their place as laws. In their turn these sciences draw on others.

The science of animal husbandry does more than apply the sciences from which it derives: it co-ordinates them. The real function of the scientific animal husbandman consists, not in the direct application of new knowledge or the mere testing upon a large scale of such hypotheses as its basal sciences may bring forth, but in the relation of new facts to existing circumstances. This implies that animal husbandry is not merely an applied science: it can evolve new techniques and can prosecute research.

Just as other sciences have various aspects, so has the science of animal husbandry. In a certain aspect one of its basal sciences may predominate. The science of animal husbandry in relation to a particular science applies that particular science to practice and at the same time takes into consideration the other basal sciences which affect the problem under consideration.

In Great Britain there is no school of scientific animal husbandry as such. Consequently this science has been largely developed by those institutes connected with agriculture which are concerned with research into the basal sciences, particularly genetics, nutrition, and physiology. Each kind of institute has, to a greater or less degree, developed animal husbandry. For example, there is the science of animal husbandry based upon the science of nutrition; the science of nutrition alone can make little contribution to the material welfare of mankind through live stock without taking into consideration the other basal sciences. Thus there are developed animal husbandmen who are primarily nutritionists but who also must have a sufficient understanding of the principles and findings of the other sciences to enable them to co-ordinate the work with which they are mainly identified. In the same way, there are animal husbandmen who are primarily either veterinarians or geneticists.

At the present time it is open to question whether the industry of agriculture can profit more from the new scientific discoveries which one may reasonably anticipate will be made by the research workers in the basal sciences or from an intelligent and co-ordinated application of that knowledge which is already available. Hitherto greater emphasis has been laid on the value of fundamental researches: and rightly so, since these are an absolute prerequisite to the proper functioning of the science of husbandry. It can, however, be fairly debated whether the time is not now ripe for an organised development of the science of husbandry. But whether this should be directed as a separate entity seems doubtful. Since its inspiration is drawn from the research institutes, separation would possibly sterilise it.

It would appear better were the science of animal husbandry to continue to be based on the various research institutes, but that the dissemination of results should be made, not through the existing county organisers (who have such a wide field to cover that they can be expert in no one subject without some sacrifice in another), but through advisory animal husbandmen, each operating in an area. These men would have no adminstrative duties. Their function would be to maintain contact with the various research institutes (they could, in fact, have their headquarters at one of these) and to apply the results of the animal husbandry sections of the various research institutes to the particular problems of their area. Such animal husbandmen would specialise in different aspects, such as pigs, horses, dairy cattle, etc. They would at the same time act as *rapporteurs* to the animal husbandry section of the research institute on which they are based. Undoubtedly there is a weak link in the chain which connects scientific research designed for the assistance of agriculture to the practice of farming. A recognition that animal husbandry exists as a science would do much to strengthen this link.

A precise definition cannot be confined to a few words. Briefly, animal husbandry may be defined as

that branch of science which interprets, co-ordinates, and finally applies the results of science to problems of live stock production.

Highest Recorded Shade Temperature.

IN the issue of NATURE for Sept. 6, 1930, at the bottom of page 386, appears an item, "Sept. 13, 1922. Highest Recorded Temperature."

The validity of the reading at Azizia has been questioned by so eminent an authority as Dr. G. Hellmann -see *Monthly Weather Review*, May 1930, page 208. Weather Bureau authorities are of opinion that the Azizia record of maximum temperature cannot be classed as having been obtained under standard conditions of exposure. We are not unmindful of the fact that it is a difficult matter to determine the maximum temperature in a shelter situated in a desert region. The chief evidence against the Azizia record is the fact that it is not supported by the readings of other thermometers in the same region, as pointed out by Dr. Hellmann, and was independently developed by the Weather Bureau climatologists.

A. J. HENRY.

U.S. Weather Bureau,
Washington, Sept. 24.

THE observations at Azizia were published by Prof. F. Eredia in 1923 (*Roma, Boll. Inform. econ.*, 1923, No. 5). After describing the site, in a plain surrounded by hills, he tells how a complete meteorological station, including registering instruments, was established in 1913, of a permanent character, *similar to the other stations installed at various places in Tripolitania.* He adds that during the period when he lived at Azizia, he determined the frequency of high temperatures from hourly observations and also from the readings of a thermograph at a temporary station near by. Referring to the figure of 58° C. (136° F.) on Sept. 13, 1922, he notes that it occurred during a period of south-west winds and almost cloudless sky. He evidently accepts the reading as correct.

I was aware of Hellmann's criticism, but in view of the above summary, and the fact that Prof. Eredia is a competent meteorologist, I concluded that the high readings were probably due to the nature of the surroundings rather than to any defect of instruments or screen. An analogous case in England was described by Miss E. H. Geake (*Meteorological Magazine*, **61**, p. 78; 1926). The lowest screen minima at Garforth, Yorks, are 15°-25° F. lower than those at surrounding stations, and this is entirely due to the local exposure!

The maximum at Azizia is only 2° F. higher than that at Death Valley, California (see NATURE, vol. 126, p. 81; 1930), which is accepted as correct by the U.S. Weather Bureau. Both stations are in depressions in arid sub-tropical regions, and both maxima are isolated readings, for the 225 stations in California for which data appear in the *Monthly Weather Review* for July 1913 do not show any other maximum exceeding 119° F. To complete the parallel, both are criticised by Hellmann as too high. To my mind, the fact that the two maxima are so nearly identical is a reason for accepting both of them.

THE COMPILER.

Ball Lightning.

A CASE of globular or ball lightning was reported to me at East Hampton last summer, and I had an opportunity of questioning an eye-witness and investigating the premises. This account has value only for comparison with other cases, and I presume someone is making a collection of reports of this nature and studying the conditions under which the phenomenon occurs.

A large modern summer residence was struck twice within fifteen minutes. The owner was standing at a window watching the approaching storm, which came up over the ocean. He states that the flashes struck in the water, coming nearer and nearer, like advancing shell-fire; then a flash to the sand dune between his house and the ocean, another in the intervening field a hundred yards from the house, and a few seconds later he found himself 'coming to' in a dazed and very shaky condition. The chimney had been struck and blown to pieces, and his arm was resting on the mantelpiece over the fireplace. He saw no flash and heard nothing, though he did not fall. Fifteen minutes later, a second bombardment commenced, and a flash struck and melted the telephone wire just outside the house, following the wires into the cellar under the kitchen, and apparently dissipating its energy among a maze of criss-crossing bell wires and furnace pipes below the kitchen floor. The thin asbestos covering of one of the pipes had been burst open in places as if by small charges of an explosive.

The ball discharge appeared in the kitchen in the centre of the room (just over the furnace pipes), about three feet above the floor, and within three or four feet of the cook, who was standing up and facing the point at which it appeared. She told me that it appeared just after the thunder crash, was yellow like a flame, about five inches in diameter, and was spinning like a top. She was very positive about the whirling, and was looking down on the thing at very close range. I asked her whether it faded away or exploded. She said, "I didn't wait to see—I jumped for the cellar door and ran down the stairs"! There was no sound of an explosion. She also stated that the room was full of a smoky haze when she returned, and that there was a strong smell. I asked her whether it was 'like sulphur' (the popular description), and she said, "No, it was acid-like." This suggests an oxide of nitrogen. No marks of the flash could be found in the kitchen, but there had evidently been a heavy electrical disturbance below the floor. The cook was near enough to the ball to touch it, and it is regrettable that she neglected the opportunity of making a valuable contribution to our knowledge of this mysterious electrical phenomenon! I think that I should have reached for it, but am not sure.

Separation of Antibodies from the Serum Proteins.

ANTIBODIES are as a rule associated with serum proteins. In view of both the high theoretical and clinical importance, a large amount of work has been done in order to obtain protein-free antibodies. The failure of these endeavours has led to the assumption that antibodies are either themselves proteins or that they are in some way closely bound to proteins.

In experiments carried out with diphtheria antitoxin and antityphoid serum, we have succeeded in obtaining active antibodies chemically free from proteins. These results were obtained by the method of adsorption and specific elution developed in their recent

studies on enzymes by Willstätter and his co-workers, who succeeded in preparing protein-free solutions of enzymes after previous autolysis of cell proteins.

Antisera diluted 1:10 were adsorbed by large amounts of kaolin (usually one part kaolin to one part serum). This mixture was allowed to stand about 24 hours at 37° and filtered. Aliquot portions of the adsorbed kaolin-serum residue were then resuspended in a number of solutions of organic substances (glycocol, glycerol, glucose, etc.), which under certain conditions are effective eluents. Glycocol was first used by Fodor and his co-workers to elute peptide-splitting enzymes from adsorbate, thus obtaining solutions of enzymes which without previous autolysis were practically free from proteins.

Our experiments showed that antibodies adsorbed on kaolin could be obtained in solutions of glycocol in 2 per cent sodium chloride. The eluates of antibodies obtained corresponded to the protein-free enzymes in that they were chemically free from proteins. Not only the usual colour and precipitation reactions like that of Millon or Esbach, but also the more susceptible Jones-Spiegler test, which indicates 0·0002 per cent proteins, were negative.

The two known typhoid agglutinins reacted differently towards elution with glycocol-sodium chloride. By elution with a solution containing about 2 per cent glycocol and 2 per cent sodium chloride, only the flagellar agglutinin was recovered. However, on diminishing the quantity of sodium chloride (0·3-0·5 per cent), the amounts of flagellar agglutinin recovered became much smaller and at the same time small quantities of somatic agglutinins appeared. The antitoxin behaved like the flagellar agglutinins.

The antitoxin content of the protein-free eluates was tested by the intracutaneous neutralisation test employed by Roemer, while the agglutinin content was determined by the usual agglutination technique. The recovered antibody in the protein-free solutions was, both in the case of diphtheria antitoxin and flagellar typhoid agglutinin, about 20 per cent of the concentration in the original sera. This does not imply that this is the maximum recoverable percentage. In these experiments we were primarily concerned with the problem whether it is possible to purify antibodies by the method of adsorption and specific elution. The problem of yield and concentration as well as the various chemical and serological questions arising from the possibility of separating antibodies from the serum proteins are under investigation.

Commensal Algæ and Reef Corals.

DR. YONGE has directed my attention to an error in my recent paper on coral reefs (*Bull. Mus. Comp. Zool.*, **71**, 6; 1930), the origin of which is of no importance. The statement is that *Millepora* and reef-building *Alcyonaria* do not possess commensal algæ. This is quite contrary to fact—for Prof. Hickson showed me them in *Millepora* upwards of forty years ago—and also to the main argument in my course of lectures delivered at the Lowell Institute at Boston. I had decalcified pieces of more than forty colonies of these various forms from surface reefs in the Indian and Pacific oceans and found that zoochlorellæ were present in all. They included *Millepora* and *Heliopora*, which in certain positions may be as important builders as reef corals, and the soft corals (*Sarcophytum*, *Sclerophytum*, and *Lobophytum*) so widely distributed on lagoon and protected reefs.

Prof. Hickson and I have recently examined between us five colonies of *Tubipora*, in all of which we have found the same commensal algæ. I did not think that they existed in *Millepora* from greater depths, having failed to find them by the teasing method in two of Agassiz's specimens of the same from more than 20 fm. Since my return to England I have found them in sections of both *Millepora* and *Heliopora* at various depths down to 50 fm., and believe them to be of universal occurrence in all these reef-builders, though varying in amount. I may add that I found these algæ in a species of the coral *Gardineria* from more than 222 fm., here presumably a parasite.[1]

The argument in the paper in question was that coral reefs have come into existence owing to the active growth of plants and of the above and other plant-animals, especially true corals, which necessarily are dependent *inter alia* on the depth to which light of sufficient intensity for their chlorophyll can penetrate sea-water. This varies mainly with the amount of plankton and other suspended material, but the maximum depth is about 50 fathoms. Under certain conditions the reef-building corals are covered by a white slime, which lies on and in the surfaces of their polyps, and ultimately kills them. This I suggest to be a precipitation of amorphous carbonate of lime from the supersaturated sea-water, owing to the chemical operations of their chlorophyll in utilising carbon dioxide. It is well seen on true corals in lagoon conditions below 10 fm., and I have found a similar slime on Lithothamnioneæ, but not on any of the other builders mentioned. If this be so, it is obvious that shoals cannot be built up on lagoon floors below 10 fm. except near passages or where there is an active flow of water. My object in writing was to induce biologists to examine this and other suggestions in the field. In particular, I should be grateful for any observations upon whether all these several animals digest their commensal algæ, if their feeding conditions are unfavourable. There are places of suitable temperature and with plenty of food, but none of these reef-builders seem to be able to live below 50-60 fm.

Laterites and Lateritic Soils.

DURING the course of the past few months I have been afforded numerous opportunities of making field observations on soils over practically the whole range of Australian climatic conditions.

A conscious look-out has been kept for evidences of tropical soil weathering processes distinctive from those of temperate regions, and for evidences of laterite formation. Two outstanding results of these observations have been: on one hand, the inability to observe any real distinction between the leached tropical soils and the corresponding temperate series usually carrying eucalyptus savannah forests, both being entirely podsolic in character; and on the other hand, the observation that every authentic case of laterite, from the geologist's point of view, was fossil in character—that is, the laterite was to be regarded entirely as a parent material from which new soils were being produced in equilibrium with current climatic conditions. In certain cases, notably in Western Australia, such soils are quite abnormal and

cannot be placed into any of the recognised soil groups. It is only when the laterite sequence has been denuded away, exposing the parent rock, that soils are found falling recognisably into one or other of the zonal soil types.

The fossil character of the Western Australian laterites in the goldfields region has already been suggested by Walther,[1] and it would be of considerable importance if geologists and soil workers could reach some mutual agreement with respect to the definition of laterites. At the present time the geologists seem to be unanimous in the recognition of laterite, although not necessarily with regard to its origin; while amongst soil workers the confusion appears to be very considerable. This confusion probably originates in the fact that the original type laterites were first described from India, and have hence been presumed to be exclusively of tropical origin.

If every authentic laterite is indeed, as in Australia, the product of a past climatic cycle, the position will be very much simplified and laterite soils will find their place in Glinka's endodynamomorphic group. In this case the points of greatest interest will be the nature and period of these past climatic conditions: one feature will certainly be greater humidity, and possibly even water-logged conditions. I doubt whether it will be necessary to bring in higher temperatures, as has been suggested in the past.

Flashing Afterglow in a Discharge Tube.

ALTHOUGH the observation recorded here may not be new, I have not been able to find a reference to it. A discharge tube was used for testing a vacuum pumping set. It was a straight tube of Pyrex glass $2\frac{1}{2}$ cm. diameter with plane nickel electrodes; the gas was air with residual gases from the walls of the apparatus; and the Crookes dark space was about 3 cm. long.

After passing a discharge from an induction coil there was a strong afterglow which persisted for several seconds, dying away apparently continuously. Before it became invisible it passed into a flashing condition, the flashes occurring at longer and longer intervals and ceasing after about ten seconds.

The phenomenon is almost certainly due to the dissipation of charges on the glass walls of the tube, as is indicated by the following experiment. Two strips of tin-foil were wrapped round the tube and connected to a valve amplifier and telephones. The 'continuous' afterglow was then accompanied by a rushing noise, and each flash in the later stage was accompanied by a loud click.

This effect may be important in the interpretation of discharge tube phenomena and in particular in work on the decay of afterglows. It is conceivable that it takes place more readily with a Pyrex tube and that this circumstance has helped it to escape notice.

Meiosis in a Triploid *Œnothera*.

MY recent statement (*Trans. Roy. Soc. Edin.*, **56**, 467-484; 1930) that a triploid plant of *Œnothera pynocarpa* Atk. and Bartl. had a closed ring of twenty-one chromosomes, has, following its questioning by Dr. Darlington (NATURE, May 17, 1930), been the subject of a reinvestigation. A brief statement of the results would seem desirable, since they confirm Darlington's observations and agree with recent work upon triploid Œnotheras, reported by Capinpin in NATURE of Sept. 27, 1930; moreover, it is as well to remove an error, as soon as it is fully comprehended, from the already too complicated field of *Œnothera* cytology.

Different nuclei at diakinesis and at the heterotypic metaphase show various combinations of the following types of chromosome groupings: univalents; ring and rod pairs; chain, Y-shaped, and ring-and-rod trivalents; various types of quadrivalents, quinquevalents, and associations of chromosomes involving higher numbers. The largest group seen was made up of a chain of eight chromosomes associated (at one end by a triple union) to one end of each of two other chromosomes, making ten in all. Analysis of all the configurations found shows that every one conforms to and may be predicted upon the segmental formula that must be assigned to this triploid on the basis of Darlington's hypothesis (*Jour. of Genetics*, **20**, 345-346; 1929).

A full statement of the facts, and of the theoretical deductions from them, is made in a paper appearing shortly in the *Journal of Genetics*.

Band Spectrum of Antimony Oxide.

I HAVE obtained and measured a large number of bands extending from λ3250 to λ6700 in the spectrum of the flame surrounding the antimony arc in air. Some of the bands were previously obtained by Eder and Valenta with different salts of antimony introduced into an oxy-coal gas flame. So far, their vibration quantum analysis has not been attempted. Some of these bands have now been classified and there are at least three systems, with origins approximately at 29619 cm.$^{-1}$, 26480 cm.$^{-1}$, and 24203 cm.$^{-1}$. The origins of the remaining systems have not yet been correctly ascertained. The bands show a doublet structure consistent with the fact that their emitter is the neutral antimony oxide molecule.

A detailed account of the investigation will be published elsewhere.

Scientific Inexactitude.

IN recent scientific writing there is frequently a tendency to abbreviate to such an extent that a reader not conversant with the subject may be completely fogged. As an example the following quotation from a recent book on sound may be given: "A clamped steel bar electrically maintained is sometimes employed as a rough standard of frequency." This unfortunate sentence is evidently the result of the general use of the contracted but incorrect expression 'an electrically-maintained tuning fork' in scientific publications. The vibrations are maintained, not the tuning fork, and if this idea is to be conveyed in shortened form a word such as 'operated' or 'driven' should be used instead of 'maintained'. This is only one example of a tendency which, if unchecked, will produce a scientific slang.

Evolution in Material Culture.*

By Dr. H. S. HARRISON.

BY the aid of *methods*, often dependent upon extraneous *means*, man employs *materials* for the achievement of *results*, many but by no means all of which persist as artefacts or other *products*.

Substance is the static warp, and method the dynamic woof, of man's material culture, whilst the products may be looked on as the fabrics, though these are not always tangible. Amongst the more obvious of those which are material in their nature are artefacts of all kinds, but it is clear that such products are themselves the means to further ends. These further ends are material in the case of implements, less immediately material in that of houses or canoes, and non-material in the case of shrines or musical instruments, which satisfy demands of social and individual mentality. Here we find our objective point of view overlapping the subjective—our material products require for their explanation some understanding of such aims and ends as lie outside the field of primary material needs. As soon as we get beyond the study of the instinctive quest of food and self-protection, and pass to that of the aims of the human artificer, we realise that aims and ends as well as ways and means are products of evolution. Man did very well before he was a man at all, and no one has given any reason why he ceased to be an ape.

THE DISTORTING MIRROR OF THE PRESENT.

Our attitude towards the problems that arise in the study of origin and development depends very largely upon the extent to which we ascribe to man a power of foresight enabling him to overrun the limits of environmental suggestion. If we assume that his progress has been based upon his opportunist reactions to such suggestion, we secure a vantage point from which to take a retrospective view of human progress. The visibility is not too good, and the details that are fundamental are often but obscurely seen, partly because the field of view is not only restricted by our ignorance but is also overshadowed by our knowledge. We can see too little of the past and too much of the present.

We have to make a big allowance for our own sophistication, when we are trying to explore the origins and growth of discoveries and inventions, and neglect of this precaution is not infrequent. In the case of pottery, for example, it is sometimes maintained that the plasticity of clay is so obtrusive, and its hardening by heat so easily made manifest, as to place the ceramic art amongst those human industries that may have been developed more than once, if not over and over again. The two essential properties of clay are obvious enough, given the conditions for its accidental hardening by fire, and both may have been discovered at various periods. Looking backward it seems evident to us that an early discoverer, looking forward, could have deduced from these two properties of clay the advantages of modelling this plastic stuff into the forms of vessels and baking them to hardness. Some may think that the deduction was an easy one, but the ease is purely retrospective. The potter was not a product of predestination. The conventional theory of the origin of pottery through the plastering of clay on the walls of baskets may or may not be acceptable, but it is in any case a recognition of the need that is felt to bridge the gap between the discoveries of two properties of clay, and the production of an earthenware pot. The discoveries were essential, but it is only in the light of our own knowledge that pottery appears to have been an inevitable result.

To take another example of the hasty reasoning which credits ancient man with anticipatory conceptions that in ourselves are due to knowledge, it is sometimes suggested that there is no improbability in the idea of the multiple origin of the pyramid, since the observation that piles of loose materials readily assumed a conical form must have been frequently made. To this it may be answered that pyramids are not small, are not made of loose materials, and are not conical in form; but this is only a small part of the relevant reply. The affiliation is indeed inconceivable, since the evolution of a pyramid depended not only upon many material factors, but also upon a number of social and religious sequences. Pyramids were not preconceived as being more pleasing to the gods, and more elevating to the human soul, than any other geometrical monstrosity; nor were they built out of mere Euclidean bravado. For such structures, even in their various modifications of material, form, and function, to appear independently in Mesopotamia, Egypt, India, Cambodia, Java, and America, would have called for parallel networks of coincidences rather than parallel chains.

MAN'S COMMON FACULTIES.

The question as to the nature and importance of the common faculties of the human mind—the components of the psychic unity—is one which demands more attention than it has yet received from anthropologists, Bastian notwithstanding. This is especially the case in relation to the subject of independent evolution. For our purposes it would not only be needful to isolate the common faculties, but also to identify those which have a bearing on the progress of discovery and invention. Here we should meet with the primary difficulty of distinguishing between an inborn human faculty and a traditional or inculcated mode of thought—an acquired type of reaction.

Assuming we had progressed so far in the comparative psychology of *Homo sapiens*, we should still be left with the problem of determining which—if any—of the common faculties are directive in their nature. It is not a question of deciding

* From the presidential address to Section H (Anthropology) of the British Association, delivered at Bristol on Sept. 4.

which faculties are permissive, enabling man to react in a similar way to similar external stimuli, but of determining which of them give him the power, whoever and wherever he may be, to override deflecting influences. Two environments may be similar, but only when they are the same are they identical, and our broad generalisations as to the cultural effect of surroundings such as deserts, mountains, forests, river-valleys, have a bearing upon the general mode of life they encourage or permit, and therefore upon a portion of the field which is open to the discoverer and inventor, but they ignore the differences in the details of any two environments of one general character; and it is discrepancies in detail that produce divergencies in end results. The human mind is very prone to skid on trifles. Moreover, even on the assumption that two similar natural environments are so nearly identical as to lead to similar reactions, under the guidance of the common faculties of the human mind, there still remains the most important factor of them all—that of the artificial environment, in gross and in detail, which formed the starting-point of two peoples whose artefacts and general culture are compared.

Taking all these difficulties into account, we see that the common faculties of man, if they are to be powerful enough to keep his independent lines of progress parallel, must be of an initiating and controlling character. If they are of such a character, history should reveal a wealth of examples of their power to keep man steadily progressing on his course, in all grades and aspects of his culture. But history has no such tale to tell, since it is merely a story of one provisional expedient following on another.

That there are mental faculties common to all men is undoubted, and it was in part by the exercise of such faculties that man secured advancement. Of the evolution of the human brain we begin to know a little, but we are not able to draw a line of demarcation between the innate and the acquired powers of its cells and tracts. In both mind and body we inherit potentialities which only unfold under certain conditions. For the development of the body we may define what are normal conditions, and they must not depart too widely from natural conditions; but for that of the mind the conditions may be almost wholly artificial. Heredity provides the aptitudes, but the grist is delivered through the sense-organs, and whilst the brain is a natural growth, the mind is a cultural construction. Human thought is compilation—a rehash of the past in the present—and no satisfactory record has ever been made of the mind of a man whose sole knowledge had been acquired without the tuition of his fellow-men.

The brain of Later Palæolithic man appears to have been like our own in all essentials, and a Cro-Magnon born to-day might become a skilled mechanic or an able bishop. But man had no more need to become a mechanic than he had to practise as a theologian, though he drifted into both professions. If the mental faculties that had survival value in the prevailing of our species were also those that were active in the initiation and pursuit of cultural advance beyond its needs, we are perhaps led to the conclusion that by far the greater part of human culture, material and immaterial alike, is an afterthought of evolution—an embroidering of the fabric. Man was given the means to earn a livelihood, and found himself commanding and inventing luxuries. In producing a new and cunning big-brained animal with hands, Nature overshot her mark, and we are struggling with the consequences.

The essence of my contention—and, of course, not mine alone—is that there are no common faculties of the human mind that are capable of overruling the vagaries of environmental and historical compulsions, and of directing man's progress in discovery and invention, in various times and places, along lines that are parallel. Beginning with the primary discoveries of early man, applied for material purposes, the prevailing outcome of his independent and opportunist reactions to the results of his own interference with natural materials and phenomena has been divergence and not parallelism.

DISCOVERY AND INVENTION.

It is obvious that discovery lies at the root of all man's material activities, since he must know something of the everyday behaviour of material substances before he can apply or adapt natural objects to his purposes. Discovery may result in the development of activities in which method remains the essential and controlling factor, as in agriculture and the domestication of animals, and we may then call the resulting system of techniques a discovery-complex; or it may initiate and further the development of artefacts, which we may provisionally call inventions. Perhaps few would be disposed to call an agricultural system an invention, and the same applies to techniques of metallurgy or weaving. If these arts are called discovery-complexes, what term may be applied to the products, such as bronze and woven cloth? Iron is an element, extracted from its ores, and man has not reached the stage of inventing elements. Bronze is an alloy of two elements, owing its first production to a series of discoveries, and we can scarcely call it an invention. We may perhaps best get out of the difficulty by using the term discovery-product for all artificially extracted, prepared, and compounded materials which have no significant form imposed upon them, but are merely the raw materials for the future production of shaped artefacts.

The application of the term 'invention' to any and every shaped or constructed artefact can only be justified on the grounds of expediency, and it must be understood that the concession is not meant to embody a definition of invention as distinct from discovery, in the relation of these words to the subjective workings of the human mind, or even to the objective results.

The word 'discovery', in its bearing on material culture, relates only to the subjective appreciation of the properties or reactions of material substances

or bodies, and it does not necessarily carry t e implication of an objective exploitation of t e knowledge gained. Only when the knowledge is applied to a useful purpose, more or less direct , for the initiation or development of a method an artefact, does the discovery play a practi l part. We may say, therefore, that a discovery s a subjective event which may in many cases e utilised in an objective application, and that it s these applied discoveries alone that are factors n human progress. It is therefore necessary to qual y the word discovery, and speak of an applied covery, before we can obtain an objective as w l as a subjective term. If we attempt to treat t word invention in the same way, and speak applied invention as the objective aspect of inve tion, we realise at once that we are doing violen to our conception of the meaning of the wor The word invention, in fact, unlike discovery, mainly objective in its significance.

Applied Discoveries.

It is clear that material progress began wi discoveries relating to materials, objects, and phen mena, of natural or chance occurrence, and th the initial value of such discoveries lay in the immediate practical use. It may have been t behaviour of stones he handled that first arous man's interest in them, but the utility of individu l stones as implements was more important to hi than the properties which made them useful. H generalising was unconscious, or even instinctiv , since animals discover, though man alone invent The making of discoveries was not the result of conscious search for means or methods to achie an end. Upon those which arose out of observ tion of simple natural phenomena, and of supe ficial properties of natural materials, were built u knowledge and experience which led man furthe and further away from his initial steps, until h was making discoveries about materials whic owed their character or composition to his develop ment of methods of treatment.

The general conclusion to which we are forced i that there are no absolute criteria by means o which we can decide what part may have bee played by independent discoveries in the produc tion of similarities in human culture. We are saf in assuming that simple primary discoveries, suc as that of the plasticity of clay, or the malleabilit of copper and gold, may or must have been mad more than once, but we are equally safe in assumin that, with every step beyond the first, an independ ent repetition of the same sequence becomes mor and more unlikely, and also that the more difficul a single discovery and the more difficult its applica tion, the less likely is its fruitful repetition.

Inventions.

The general recognition of the gradual character of the evolution of human artefacts—so obvious even under modern conditions—makes it unnecessary to dwell upon it. There are, however, no accepted definitions of the kinds of developmental changes or modifications, viewed either objectively or subjectively. If the initial steps in the evolution of simple artefacts are due to discovery alone, as already suggested, we have to decide in what way such steps differ from those which can be called inventive, if difference there is; and also to inquire into the nature of any other factors that may play a part in evolution. Moreover, if we call all artefacts inventions, there is no term left for single inventive steps. If, for example, the outrigger-canoe or the Chinese repeating crossbow is an invention, what distinctive term can we apply to the steps by which it has evolved, assuming these can be identified as due to individual discoveries, or to true inventions, whatever these may be? There is also the possibility—or the certainty—that changes may occur which are due to neither discovery nor invention, but to some slower and more gradual process.

If we begin with implements which were amongst the first to achieve an individuality of their own, those made of stone are for many reasons the most convenient for our purpose. We can scarcely doubt that accident, perhaps often repeated, led to the intentional breaking of stones for the production of edged or pointed implements, which gradually evolved into standardised forms. To summarise a sequence of events that arose out of more than one discovery, we may say that the first artificially shaped stone implement was due to the application of a discovery, and since the artificial shaping was a definite and decisive step it may be called a *mutation*. Since also it was the first intentional conversion of a particular kind of natural object or material into a kind of artefact it was a primary mutation. From such a mutation perhaps occurring more than once, developed the many forms of stone implements with which we are familiar. A mutation of this or any other type is an abrupt and discontinuous step, contrasting with changes which are trivial in character and produce their effect by a process of summation. For these the name of *variations* is appropriate.

In the shaping of the early types everyone agrees that forms such as hand-axes and 'ovates' were not preconceived as models to be aimed at; they must have been the end results of a gradual process of change, in which the shapes emerged through an opportunist selection and imitation of those which were most convenient and effective. This was in effect a process of variation, casual at first but later becoming more selective and adaptive.

Simple stone implements are thus to be traced to a primary mutation, a sudden jump, followed by variation, a gradual process. They were evolved, not invented to serve specific purposes. Similarly, beginning with a primary mutation in each case, the fighting-stick became the club, with its immense variety of form; the digging-stick became the spade, and perhaps the spear, with its derivative the arrow; the pick became the hoe and finally the plough; the hollow reed became the blow-tube. Even before the more evolved implements of these classes had got beyond their one-piece

sometimes intervened. That is to say, whilst the field of variation is that of form, it is not in exclusive possession of this field.

If a primary mutation was due to one or more discoveries made in relation to the behaviour of natural objects or materials, it is not unreasonable to suppose that similar discoveries concerning artefacts may have led to other mutations. As a hypothetical case, let us consider the origin of the bamboo spear-thrower of New Guinea, which has a socket for the spear, in place of the peg that is present on almost all other spear-throwers. We may suppose that this implement was derived from the ordinary type made of wood, such as is in common use in Australia, and that the first change was that of translation into bamboo. The carved or attached peg for the spear was at first retained, but during the manufacture or use of the appliance it would be easy for the discovery to be made that the bamboo rod readily supplied a natural socket, which would serve in place of the peg for effecting the discharge of the spear. Then followed the intentional construction of spear-throwers with socket instead of peg, and we may call the step —which may or may not be regarded as a progressive step—a free-mutation. If it happened as the result of a discovery, as suggested, it was free from any influences from other implements or mechanisms. It is impossible to be sure that no such outside influence was at work, but the step being decisive and discontinuous, it was at any rate a mutational step and not variational.

We may assume with some degree of probability that free-mutation initiated the provision of the foot-rest on the digging-stick, a grip or handle on the stone knife, the detaching head of the spear to produce the harpoon, the sling-hafting of the flail, and that it was concerned in the origin of other types of hafting. Primary mutation, followed by variations which led to change in form, stimulated by discoveries in relation to method, and often influenced by substitution, led to other discoveries which could be applied for the improvement of the form or construction of artefacts, and these applied discoveries may be called free-mutations. In this way there were produced many implements of a simple character, some having form alone, others showing construction and often mechanism.

So far we have identified no inventive foresight of a kind that would lead directly to the subjective preconception of a new or improved type of implement, differing in any important respect from what had gone before. We know, however, that in our own times the inventor designs his products in advance. This is not to say that at some stage in the evolution of material culture there was a sudden change in the mentality of man. Discovery and imitation lay at the root of all his methods, initiated all his artefacts, and led to the appearance of free-mutations, but when he had established a variety of artefacts that had construction as well as form, he began that process of transfer and adaptation of structural and mechanical characters for which I have suggested the term cross-mutation. These, like the other mutations already defined, were abrupt and discontinuous changes which could not have arisen gradually by variation, but, unlike other mutations, they owed their origin to a combination of features, or an application of 'principles', which had evolved in independence.

The process corresponds to what Mr. Henry Balfour has laid stress upon as hybridisation. It is a process involving foresight, in predicting the possibility of combination, and ingenuity in effecting it. A cross-mutation is a true invention, a product of the inventive faculty, unaffected by discovery in its first conception, though the inventor nowadays may need to make discoveries in relation to materials and methods before he can test the viability of his inventive forecast. Through it all runs the opportunist thread that may be plainly seen in the historical retrospect. Combinations for inventive purposes can only occur to the mind in an artificial environment in which the two (or more) elements of the combination are at hand, and these may have been evolved in entirely different artefacts or contexts.

Accepting these arguments as valid, an invention proper—as distinct from our loose application of the term to shaped and constructed artefacts in general—may be defined as a single mutational step which owes its origin not to discovery, but to a combining of structures or devices already in existence. The result is objectively a structural combination, which is preceded subjectively by the action of the mind in recognising the advantages and the possibilities of the hybridisation, and in thinking out the method of effecting it.

In a further treatment of the subject of inventions it would have been desirable to discuss such factors as change of function, change in method of use, substitution, and numerical mutation, but sufficient has been said to indicate the analytical method of approach.

If we take into account all the factors involved in the development of artefacts, even in simple cases, independent evolution involves coincidences, few or many. It is also clear that the further the artefact from the primary mutation which began it, that is to say, the longer the series of variational and mutational changes that has been undergone, the bigger the draft on coincidence. Nevertheless, we are still unable to point to definite mutational criteria, and to say that it is impossible that some particular mutation—and especially a primary mutation—should have occurred more than once. But a primary mutation is only a first step. As in the case of discovery-complexes and discovery-products, it is necessary to consider each case on its merits, and endeavour to identify all the links in the evolutionary chain.

The general case against identity or similarity by independent evolution is, however, overwhelming, as is very widely admitted at the present day, but to a large extent it is based on cumulative circumstantial evidence, since there are grave difficulties in finding proofs that leave no loophole for the defence.

Periodicity in Australian Weather.

METEOROLOGISTS generally recognise that as the sun's radiation heats the earth's surface, provides the energy of winds, and evaporates the water which falls as rain, so most of the variations from year to year in temperature, wind, and rainfall must be in some way caused by variations of solar radiation. The literature of the subject is immense, but is mostly directed towards discovering direct and simple relationships between solar radiation, especially as represented by Wolf's sunspot numbers, on one hand and terrestrial weather on the other hand. With a few isolated exceptions, however, these efforts have met with little success, probably because a simple direct connexion rarely exists, the solar changes working rather through complex changes in the atmospheric circulation. In a recent paper,* Dr. E. Kidson approaches the problem, as it affects Australia, by studying the variations in the tracks and intensities of the moving anticyclones which traverse the country from west to east. The data employed were extracted from the Australian daily weather charts (usually including New Zealand) for the years from 1887 onwards; they are expressed in various ways, including the average latitude of the centres in different longitudes, the annual range in the latitude of the centres, the intensity, and the rate of travel, all of which give fairly concordant results.

The most obvious periodicity in these data is not the sunspot cycle of eleven years, but a shorter one of only eighteen months. The effect is not large – the range between the most northerly and the most southerly positions of the average tracks is only one or two degrees of latitude—and the data require smoothing to bring out the periodicity, but from an inspection of the unsmoothed figures it is probably real. The author believes it to be of terrestrial origin, and he writes: "An eighteen-months period in terrestrial phenomena may at first sight appear unnatural, but it is a period between a season in one hemisphere and the next but one of the same kind in the opposite hemisphere. This suggests an oscillation between the hemispheres which would be of quite a natural type."

Now one of the most striking features of Australian meteorology is a three-year cycle in the pressure of Darwin, which is the basis of long-range forecasts of rainfall in Java. A similar periodicity is widely distributed in other parts of the world, and the author suggests that this is really the same eighteen-month periodicity of the circulation which, having opposite effects according as its maximum falls in summer or winter, actually appears as a three-year cycle. This would account for the frequency with which the latter is interrupted by a secondary maximum. Moreover, this apparent three-year cycle at Darwin is not constant, but breaks down from time to time. These breaks are all near sunspot maxima, and this suggests that the cycle is controlled by solar variations and so kept in step with the eleven-year sunspot cycle. So we arrive at a mechanism in which seasonal changes, a natural oscillation of the earth's atmosphere, and solar control all combine to produce complex variations of weather.

The second half of the paper is devoted to the effect of the sunspot cycle in the rainfall of Australia. The rainfall data are grouped into districts, and the annual totals for each district are then combined to obtain the average variation during an eleven-year cycle. The curves produced in this way are mostly very irregular, and are smoothed over three years. This is legitimate as a graphical process, but the high correlation coefficients which the author obtains between these much smoothed rainfall data and the sunspot figures similarly smoothed can have little significance, and the arguments which he bases on them correspondingly little weight. The deduction of the eighteen-months cycle rests on surer ground, though the question whether this or the well-established three-year cycle is the real primary oscillation seems to need further consideration. C. E. P. B.

Obituary.

DR. H. R. H. HALL.

BY the premature and sudden death, on Oct. 13, of Dr. H. R. H. Hall, the British Museum loses one of its most active and distinguished Keepers, and a large circle of colleagues and friends a genial, generous, and wholesome personality. Hall was born on Sept. 30, 1873, educated at Merchant Taylors' School and St. John's College, Oxford, and appointed to the Department of Egyptian and Assyrian Antiquities in 1896, during the long keepership of Sir E. Wallis Budge. He was promoted Assistant Keeper in 1919, and succeeded his old chief as Keeper in 1924.

Hall's father was an artist, and the dedication of Hall's first book, "The Oldest Civilisation of Greece" (1901), acknowledged and exemplified a very real debt, in its keen appreciation of the beauties as well as the scientific interest of that Ægean culture which he was one of the first to popularise in Great Britain, even before the Cretan material was available. To this culture, though it lay only on the outskirts of his professional studies, he recurred often and lovingly, in his "Ægean Archæology" (1915) and his Rhind Lectures of 1923, published in 1928 as "The Civilisation of Greece in the Bronze Age" with a wealth of illustration which testified to his mature artistic judgment. For, as he wrote, characteristically, "the plan of each lecture as delivered was to explain the pictures". At need, he would come back to Oxford, after his Museum-day, to 'explain pictures' on this favourite theme. Yet this was only one of

many personal interests, ranging from Dutch pictures to army buttons, wherein Hall's exuberant boyish vitality found expression. For him, as for Stevenson's happy child, "the world was so full of a number of things".

Meanwhile, in the Museum, Hall rapidly mastered the difficult technique of both sides of his department, Egyptian and Assyrian. He published hieroglyphic texts, Coptic and Greek documents almost as difficult, scarabs combining linguistic and historical with artistic problems, early metal-castings from Al-'Ubaid, and the monumental architecture of Dair-el-Bahari. A great museum's exhibition galleries rightly reflect the personality and outlook of its keepers, in liaison between the advance of learning and the broadening interests of its popular visitors. Certainly, with his keen eye for colour and modelling, and his strong historical sense of perspective, Hall left appreciably brighter as well as more intelligible those halls along which, swinging his keys, you met him striding as if over downland.

It was Hall's good fortune—as well as due to his quality—that he was one of the first assistants in the British Museum to be allowed, and later sent, to take part in excavation abroad; a practice now well established, and amply justified by its effects, as the recent Royal Commission has testified. Hall's first campaigns were with the Egypt Exploration Fund at Dair-el-Bahari (1903–7) and at Abydos (1910), under the veteran Edouard Naville, and with Prof. T. E. Peet in the party. At Abydos he excavated again in 1925. The War brought him in time, like other archaeologists, to the countries he most needed to visit, as a captain in political service in Mesopotamia; and as soon as circumstances permitted he organised the great series of excavations which the Museum has conducted jointly with the University of Pennsylvania, at Ur and in its neighbourhood, and himself discovered and brought home the wonderful early statues and relief work in copper from Tell-al-'Ubaid, published in the first instalment of "Ur Excavations" (1929). As responsible Keeper, after 1924, he was no longer able to conduct this field work; but the successes of Mr. C. L. Woolley and his colleagues owe much to his vigorous, methodical, and tactful conduct of the home-front.

Probably Hall's best-known book was an "Ancient History of the Near East", first published in 1912. It was the first handbook of the kind in English, since the days of Rawlinson, and is in its seventh edition; the soundness of its conception and workmanship is attested by the very small amount of remodelling which it has needed, in a period of rapid, multifarious discovery. Without attempt at fine writing, Hall tells his story as of a living world, with a historian's training, the museum-man's gift of easy reference to required fact, and the broad humanity and common sense characteristic of all he said and did. That indeed is what his Trustees, other learned institutions, and the Government valued in him increasingly; and his untimely death followed over-exertion as their representative at a series of important conferences abroad.

J. L. M.

WE regret to announce the following deaths:

Prof. Adolf Engler, formerly Director of the Botanic Garden and Museum at Berlin-Dahlem and joint author with Prantl of "Die Natürlichen Pflanzenfamilien", on Oct. 10, aged eighty-six years.

Col. J. W. Gifford, a pioneer in the use in Great Britain of X ray photography, who also contributed to the improvement of telescopic lenses, on Oct. 27, aged seventy-four years.

Mr. J. E. Purvis, of Corpus Christi College, Cambridge, who had been University lecturer in chemistry and physics as applied to preventive medicine since 1909, on Nov. 1.

Mr. B. B. Woodward, an original member and past-president of the Malacological Society of London, formerly librarian of the British Museum (Natural History), on Oct. 27, aged seventy-seven years.

News and Views.

THE Rede lecture delivered by Sir James Jeans at Cambridge on Tuesday last, on "The Mysterious Universe", was marked by the clarity and suggestiveness to which we have grown accustomed in his welcome utterances. Starting with the conception of mankind as the product of an accident in a universe the main course of which was quite other than towards the production of human life, he reviewed the successive ideas which these chance creatures have held of the universe outside themselves. He enumerated three stages, represented by an anthropomorphic, a mechanical, and a mathematical view of the nature of the reality behind phenomena. The last of these has lately been introduced by the advance of physics, and Sir James regards it as a far closer approximation than its predecessors to the 'ultimate reality', with which, however, we are not yet in contact. He made no attempt to evade issues which are the subjects of acute differences of opinion. "We discover", he said, "that the universe shows evidence of a designing or controlling power that has something in common with our own individual minds—not, so far as we have discovered, emotion, morality, or æsthetic appreciation, but the tendency to think in the way which, for want of a better word, we describe as mathematical." "This concept of the universe as a world of pure thought", he went on, "implies, of course, that the final truth about a phenomenon resides in the mathematical description of it; so long as there is no imperfection in this, our knowledge of the phenomenon is complete."

To Sir James Jeans, as—rather less tentatively—to Sir Arthur Eddington, the recent developments of physics seem to rule out determinism from the course of Nature. "The old science had confidently proclaimed that Nature could follow only one road, the road which was mapped out from the beginning of time to its end by the continuous chain of cause and effect; state A was inevitably succeeded by state B. . . . The new science . . . can . . . specify the relative probabilities of states B, C, and D. But,

just because it has to speak in terms of probabilities, it cannot predict with certainty which state will follow which." Sir James Jeans's views will not meet with general acceptance, and indeed it was one of the merits of the lecture that it was provocative of far more thought than it expressed. While it may be true that physics has led to a mathematical conception of Nature, it may well be asked whether it could possibly do anything else. The mechanical view which has been displaced was itself fundamentally mathematical, and the 'displacement' is in reality less a substitution than a purification. We may well ask whether we are justified in concluding that a mathematical description of a phenomenon is a complete one when our means of investigation could scarcely yield anything more. How could an æsthetic description, for example, supposing it to be possible, be given by the methods of physics ?

SIR JAMES JEANS dealt briefly with this point, but his remarks will probably not give universal satisfaction. Incidentally, we may note also that the view he advances is not altogether a modern one: it was not, in fact, unknown to the ancient Greeks, to whom the universe was a problem in geometry. "The Creator", says Plato—of whose ideas in another connexion Sir James Jeans made a striking application—"practises geometry eternally." The bearing of the new physics on the problem of determinism, too, is perhaps not so simple as it appears. It is not sufficiently emphasised nowadays that the departure from strict causality exists, if at all, only in a purely conceptual world, which, by its own innate requirements, can never possibly be observed. The determinism of Nature is not removed but merely re-interpreted, and the whole question is given an illusory bearing on the problems of philosophy and religion by the employment of the word 'probability' in a different sense from that in which it is generally understood. Sir James's lecture will serve a more than useful purpose if it becomes the means of dragging these questions out of the confusion in which they are now deeply immersed into the air of clear thought.

WHATEVER his political creed, no one familiar with the scientific work done by the dyestuffs industry in Great Britain could fail to be moved to uneasiness by the impending lapse of the Dyestuffs (Import Regulation) Act. The safeguarding of this new and virile national industry is not a matter merely of economic importance, although from this point of view and in relation to the volume of employment it is serious enough. The question, however, of the continuance of the protection is one which ought not to be regarded as necessarily being subject to the same mode of approach, or debated on the same political principles, as may fairly be applied to the general case of tariffs versus free trade. It has to be remembered that there are bound up with the fortunes of this branch of our chemical industry wide and serious problems of national scientific development in directions which lead far from the immediate interests of the colour industry.

THE Institute of Chemistry of Great Britain and Ireland has recently published a statement referring to the influence of the Dyestuffs Act during the past ten years on the education of British chemists and on the progress of research in industry. During this period of assistance, the laboratories maintained by the dyestuffs industry in Great Britain have followed the example of those established long ago in Germany, by serving as the focus of research and development not only in the extending range of coal-tar products but also generally in the domain of applied organic chemistry. This most desirable movement has called into being an adequate corpus of skilled chemists and technologists, and the protection afforded to the industry has encouraged the provision of substantial facilities for instruction and research. In short, good progress has been made along sound lines towards the re-establishment, on an independent footing, of our coal-tar colour industry; the future both of the industry and of organic chemistry in Great Britain would, however, be jeopardised if the Act were allowed to expire forthwith.

IT is announced that the Nobel Prize for Medicine for 1930 has been awarded to Dr. Karl Landsteiner, of the Rockefeller Institute for Medical Research, New York. Dr. Landsteiner was born in Vienna in 1868, and was educated at the University of Vienna, where he became professor of pathological anatomy in 1909, holding this chair until 1919, and becoming attached to the Rockefeller Institute in 1922. His published work includes studies on the virus of fowl plague and on infantile paralysis. In immunology, he has devoted much attention to the characters and individual differences of human blood as regards blood groups, corpuscular agglutinins and agglutinogens, and their inheritance, and to the serological properties of the blood of the anthropoid apes. He has also published investigations on the formation of bacteriolytic immune bodies, cell antigens and specificity, and serological specificity and chemical constitution.

OF the many pioneers of the steamboat, to Henry Bell—the centenary of whose death falls on Nov. 14—belongs the distinction of inaugurating steam navigation in the Old World, just as to Robert Fulton belongs the honour of inaugurating steam navigation in the New World. Fitch, Rumsey, Miller, Stevens and Symington had all achieved a certain amount of success with their experimental boats, but it is with the passages of Fulton's *Clermont* on the Hudson in 1807 and of Bell's *Comet* on the Clyde in 1812 that the history of the steamboat as a regular means of transport begins. Neither Fulton nor Bell were the originators of steam propulsion; neither of them constructed either the hulls or the machinery of their boats; neither of them introduced any improvement in steam engines or boilers; but it was to their imagination, confidence, and courage rather than to their mechanical ingenuity that they owed their achievements. Of the two, Fulton undoubtedly possessed in a greater degree the qualities requisite to a great pioneer, but our debt to Bell is not lessened thereby.

BELL was born in the Old Torphichen Parish Mill, Linlithgow, on April 4, 1767, and died at Helensburgh on Nov. 14, 1830. Brought up as a mechanic, he had worked under Rennie in London and had been the partner of a builder in Glasgow before settling in 1808 in Helensburgh. At this place he was proprietor of the Baths' Inn, and it was for conveying customers between Helensburgh and Glasgow that the *Comet* was built. Laid down in October 1811, at Port-Glasgow, the vessel was launched on July 24, 1812, and began running during the following month. Seven months later she found herself with a rival, and in 1813 no fewer than five steamboats were afloat on the Clyde. These proved superior to the *Comet*, which Bell tried for a time on the Forth and then on the west coast of Scotland, until on the afternoon of Dec. 15, 1820, she was caught by the tide and cast ashore off Crinan, and broke in halves. The forward part holding together, the engine was salved and to-day stands in the Science Museum, South Kensington. In spite of his efforts, Bell's fortunes never rose high, and during the latter part of his life he was given a grant by the Government and an annuity by the Trustees of the River Clyde. At his death he was buried in the parish churchyard at Rhu, near Helensburgh, and many years later the famous shipbuilder, Robert Napier, erected his statue there. A granite obelisk to Bell's memory was also set up on the front at Helensburgh, while another memorial at Bowling recalls his services to those who have occasion to pass up and down the most important shipbuilding river in the world.

A STRONG earthquake occurred on the morning of Oct. 30 along the sea-coast of the province of the Marches in Italy. The epicentre was probably submarine and close to the small town of Senigallia (near Ancona), where one-third of the buildings were destroyed, another third seriously injured, and ten persons lost their lives. Slight shocks were felt at Trieste (142 miles from Senigallia), Padua (145 miles), and Naples (195 miles), so that the area disturbed may have contained so much as 120,000 square miles, a rather unusual size for an Italian earthquake. Sea-waves are said to have swept the adjoining shores and damaged some of the quays, indicating, if the report is correct, that there was some displacement at the epicentre. The Kew seismographs recorded an earthquake of moderate intensity at 7 h. 16 m. 7 s., G.M.T. All along the coast of the province of the Marches, there are, according to Dr. M. Baratta, a number of minor seismic zones. Senigallia lay within the meizoseismal areas of the destructive earthquakes of Rimini in 1672 and Ancona in 1690, but the earthquake that bears the closest relation to the recent shock is the Senigallia earthquake of Sept. 21, 1897, by which nearly all the buildings in the town were more or less damaged. The epicentre was probably a few miles off the coast at Senigallia, and the disturbed area about 175,000 square miles.

FOR some years past, there has been a wish on the part of some of the inhabitants of Bournemouth to establish there a natural history museum. In 1912, Sir Ray Lankester addressed a public meeting upon this matter, and recently, Mr. J. B. Calkin, of Bournemouth, has been instrumental in again urging the need for such an institution. A letter signed by a number of influential citizens has been forwarded to the mayor, but it was felt that this should receive support of a more public nature, and an invitation was sent to Mr. Reid Moir, president of the Ipswich Museum, to address the Bournemouth Rotary Club upon the question. The meeting was held on Oct. 28, and was fully representative of the scientific and municipal life of Bournemouth. Mr. Reid Moir, after outlining the great richness of the area from the geological, archæological, and other points of view, remarked that a vast mass of important material has already left the district, and that this regrettable process will continue until a properly equipped museum is in existence to receive it. He urged the necessity of such provision, and suggested that, in its initial stages, the museum should be of a more or less local character. Mr. Reid Moir also stressed the ever-growing importance of museums in national education, and outlined the nature and value of a modern museum of natural history. He emphasised the need for erecting the building on a site where expansion can take place, and the expectation that large numbers of visitors to Bournemouth would be attracted to the museum. Judging from the support given to the proposal at the meeting, it is hoped that, before long, this progressive town will possess an adequate and up-to-date exhibition of objects of natural history.

MOST towns of considerable size have their occasional exhibitions to illustrate and commend the use of gas, the use of electricity, developments in domestic utensils, and so on, but few contemplate an exhibition to illustrate the wonders of science, as Hastings has done in recent years (NATURE, Oct. 25, p. 658). Of course, the practical exhibitions are backed by the hope of ultimate financial gain, while the wonders of science are fortunate to escape without financial loss; but nevertheless it is a little disturbing to think that the men of commerce are more determined to proselytise the people for a material end, than the men of science generally are for a spiritual. The attempt at Hastings to interest the people in science and add to their knowledge by means of a temporary Science Exhibition, accompanied by demonstrations, science talks, and formal lectures, is therefore to be encouraged. Such an exhibition can be planned in detail and carried out only by scientific men, but the organisation and the financial arrangements must be in the hands of a municipal or other authority, capable of looking beyond the monetary balance-sheet to the educational benefits which follow. Co-operation between municipalities, museums, and teaching institution, to this end should be readily obtained, and we trust that other towns may follow the lead which Hastings has given in introducing to the public some of the wonders of science.

AN exhibition illustrating the utilisation of photography in astronomy, arranged by the Royal Photographic Society of Great Britain, is being held at

the Society's rooms, 35 Russell Square, W.C.1, on Nov. 4–29. The exhibition is the second of a series planned by the Society to illustrate the uses of photography in the service of man. The Society is to be congratulated on having secured a comprehensive series of photographs representing the work of observatories and of individual astronomers not only in Great Britain but also in Canada, Egypt, France, Germany, India, South Africa, and the United States. The increasing application of photography to astronomical observations during the last fifty years has been rich in results to an extent almost unimagined, and there is ample evidence of this in the four hundred items of the exhibition. The number of exhibits requiring technical discernment for their full appreciation, such as solar and stellar spectra, is in reasonable proportion, and in many cases where the subject under illustration is not obvious, simple descriptions have been appended. The exhibition is worth careful inspection for more than one reason. In several instances exhibits have been arranged to present some elementary fact of astronomical observation—the sun's rotation, the rapid changes of solar prominences, the changing appearance of the surface of Jupiter with the shadow of a satellite—whilst the latest discovery pertaining to the solar system is shown by a photograph of the planet Pluto.

A FEW photographs of historical interest have been included in the Exhibition of Astronomical Photography to show the march of progress; one views with respect the results achieved by those early workers who used a wet plate or a recently invented dry plate with what would now be considered limited telescopic equipment. Concerning the wealth of recent work represented—it would be invidious here to particularise—astronomers have sent of their best results, and one cannot fail to be impressed with their spectacular record of many of the grandest aspects of the heavens known to man. In connexion with the exhibition, Prof. H. Dingle will deliver a lecture on "Spectrum Photography", on Nov. 17, and Mr. J. H. Reynolds will give "A Talk on the Slides and Films in the Exhibition", on Nov. 24. The Exhibition is open free to visitors between 10 A.M. and 5 P.M. on each day, except on Sundays. No tickets are required for the above lectures at 7 P.M.

ON Friday, Oct. 31, a public lecture on "High-Pressure Reactions" was delivered before the Institution of Chemical Engineers by Prof. W. A. Bone. Prof. Bone dealt briefly with the historical events leading up to an understanding of the rôle played by pressure in gas reactions. Within a period of less than fifty years has been included the first recorded synthesis of ammonia from its elements by the agency of a catalyst, the statement of the principle of mobile equilibrium, and the classical work of Haber and his collaborators upon equilibrium in an ammonia-nitrogen-hydrogen system. A more recent development has been the synthesis of various organic compounds from water-gas by the employment of suitable catalysts and high pressure, which has opened up a wide field for future exploration. The variety and complexity of these new processes, however, require much systematic and fundamental research before a clear understanding of their mechanism is obtained. One of the difficulties encountered in high-pressure gas reactions is the lack of reliable fundamental data on the physical properties of gases. No more useful link could be undertaken at present than a comprehensive determination or re-determination of such data as the compressibility of gases and of mixtures of gases and the effect of pressure on viscosity, dielectric strength, solubility, and thermal conductivity. Although such work falls within the scope of a high-pressure gas research laboratory rather than of a works routine laboratory, the cost of equipping and maintaining such a laboratory has hitherto proved an insuperable barrier. Some three years ago, however, a complete high-pressure gas research laboratory was established in the Department of Chemical Technology at the Imperial College of Science, and work has been commenced on a number of physical problems directly connected with high-pressure reactions. Prof. Bone's lecture will appear in full in the *Transactions* of the Institution of Chemical Engineers, vol. 8.

THE British School of Archæology in Egypt has found recently in the Wadi Gaza, and its tributary valleys in Southern Palestine, a very important series of flint implements of Lower Palæolithic types. These specimens, which were described by Mr. Reid Moir at a meeting of the Royal Anthropological Institute on Oct. 28, can be divided into two sharply defined groups, the oldest comprising coarsely flaked rostro-carinate implements, rostroid hand-axes, choppers, and points. There is no doubt that these specimens, in their method of evolution, forms, and technique, are comparable with others found in East Anglia and elsewhere, and known to be of Early Pleistocene date. The latter implements exhibit usually striation and abrasion by ice-action, while the Palestinian examples, which have not yet been discovered *in situ* in any ancient deposit, show manifold signs of collisions with other stones in rapid movement. It is supposed that the ice-sheets present farther north were represented in Palestine by extensive snowfields, which, on melting, gave rise to widespread floods, and the abrasion of any implements exposed to such conditions.

THE second group of Palestinian specimens described by Mr. Reid Moir differs very markedly from the first—as they are quite unabraded, and comprise beautifully made hand-axes of Late Acheulean types. Some of these implements have been found *in situ* beneath a considerable depth of sand at Sherah. It is evident that both the archaic and the later groups of specimens from Palestine were made each by a differing technique and upon a highly specialised plan. Further, it can be demonstrated that a precisely similar method of implement-making was in vogue in England, Africa, and India in remote times. It seems necessary to suppose that centres of dispersal of cultures existed in prehistoric times, as it is not a reasonable supposition that a race of people living, for example, in Palestine would, by coincidence, proceed to make their flint implements on the same

complex plan as that adopted by another race in England or India. The existence of these world-wide cultures in the Lower Palæolithic epoch appears to imply that the human race was even then more highly organised than has been hitherto supposed, and that very extended periods of time were involved in the spread of certain "fashions" in implement-making over such wide areas of the globe.

IN *Engineering* for Oct. 31 is an illustrated account of the closing of the arch span of the great Sydney Harbour Bridge in August and September. The span, which is 1650 ft. between the main supports, has been erected as two cantilevers from either side, each cantilever being supported by 128 steel wire cables connected to the top chord at the end of each end post, and carried down to the solid rock through a tunnel 120 ft. deep. The steel-work has been put into position by creeper cranes, each 605 tons in weight, travelling on the tops of the half-arches. There are fourteen panels in each half-span, and when thirteen and a half of these had been completed the total pull on the cables was 27,440 tons. When sufficiently far advanced for joining both upper and lower chords, the load was lessened on the cables one by one by means of hydraulic jacks. Included in the article are photographs of the forged steel saddles, with their alignment pins, for the bottom chords, and the jacking arrangements by which the correct compression was obtained in the upper chords. The forcing apart of these chords was done by means of four hydraulic jacks of nickel steel, each of 950 tons capacity.

AT the invitation of the Ministry of Agriculture and Fisheries, three committees of the International Council for the Exploration of the Sea met at the Fisheries Laboratory, Lowestoft, during the first week in November. Several foreign delegates and experts were present, and the president of the Council, Mr. H. G. Maurice, presided over the meeting of the Executive Committee, or Bureau. The other two committees dealt respectively with the plaice and the herring. It has long been known, as the result of marking experiments, that small plaice transported from the over-crowded grounds on the Continental coast to the Dogger Bank will grow very much faster on this famous fishing ground, and the Council decided at the last meeting that the possibility of carrying out such transplantation on a large scale should be very carefully examined. A committee has therefore been constituted to study the financial aspects of the question and to decide, if possible, whether the transplantation of, say, one million plaice can reasonably be expected to yield a commercial profit. The committee on the herring includes in its membership the principal experts from all countries bordering on the North Sea. It is engaged principally on technical questions, its main task being to secure uniformity and standardisation of methods of research and closer co-operation in the study of the herring. A scheme was presented by the English fishery workers for a more detailed study of the herring in the southern North Sea, with the view of rendering more exact the predictions of the great East Anglian herring fishery, which have already been made with some success.

A SCIENTIFIC Advisory Committee on Medical Administration and Investigation has been appointed by the Secretary of State for Scotland "to assist the Department of Health for Scotland in applying the results of scientific research to the details of public health administration and in promoting such medical investigations as come within the sphere of the Department or of the local authorities in Scotland". The members of the Committee are: Dr. Alexander Bowman, Scientific Superintendent, Marine Laboratory of the Fishery Board for Scotland; Prof. C. H. Browning, professor of bacteriology, University of Glasgow; Prof. E. P. Cathcart, professor of physiology, University of Glasgow; Prof. F. A. E. Crew, professor of animal genetics, University of Edinburgh, and Director of Animal Breeding Research Department; Sir Walter M. Fletcher, Secretary to the Medical Research Council; Sir Robert Greig, Secretary, Department of Agriculture for Scotland; Mr. John Jeffrey, Secretary, Department of Health for Scotland; Dr. J. Parlane Kinloch, Chief Medical Officer, Department of Health for Scotland; Dr. A. S. M. Macgregor, Medical Officer of Health, Glasgow; Prof. T. J. Mackie, professor of bacteriology, University of Edinburgh; Prof. J. J. R. Macleod, professor of physiology, University of Aberdeen; Prof. Robert Muir, professor of pathology, University of Glasgow; Dr. J. B. Orr, Director of the Rowett Institute for Research in Animal Nutrition, Aberdeen; and Prof. W. J. Tulloch, professor of bacteriology, University of St. Andrews. Dr. Parlane Kinloch is chairman, and Mr. George Wallace, of the Department of Health for Scotland, is secretary of the committee.

IT is announced in the *Museums Journal* for October that the Carnegie Trustees are now prepared to receive applications for grants from small museums administered by public authorities, under the following conditions, which will be strictly observed: (1) The grants will not exceed £250 to any one museum. (2) The museum authorities must show that they are prepared to adopt some definite policy and are re-organising their institution on the lines recommended by Sir Henry Miers in his 1928 Report to the Trustees. They must also show that they are prepared to provide an adequate annual revenue for the upkeep of the institute under the new policy. (3) The grants are to be confined to towns with between 10,000 and 70,000 inhabitants. They will be given in respect of capital expenditure only on the £ for £ basis. They will not be available for the erection or structural alteration of buildings, or for ordinary current expenditure. They are to be expended on special outlays (for example, purchase of cases, employment of temporary staff) in connexion with the reorganisation schemes in respect of which they are sanctioned. (4) Each museum applying must have, or be prepared to appoint, a competent curator. Applications should be addressed in the first instance to the Secretary, Carnegie United Kingdom Trust, Comely Park House, Dunfermline, Fife, Scotland.

THE *Australian Museum Magazine*, a quarterly edited by Dr. Charles Anderson, an Orcadian by birth, manages well to strike the balance between pure

science and popular reading. But the July-September number especially interests us, apart from its articles, by the evidences it contains of the activity of the Australian Museum. Notices on the covers direct attention to new series of postcards illustrating in four-colour process typical beasts and birds of Australia; other notices are attractive invitations to special exhibits in the Museum and to a series of popular scientific lectures in which "the subjects dealt with will be presented in a clear, lucid, non-technical manner, making known many unfamiliar facts concerning Nature and her ways". Finally, the telephone extension number of each specialist on the staff is given, and visitors are invited to apply for information, when they "will receive every attention from Museum officials". These are excellent methods of making the public feel that the Australian Museum exists for their service, and so of obtaining the widest public assistance and support. Museum officials in Great Britain perform the same services, but it is well that the public should be reminded so frankly of the willingness of the museums to help in the spread of scientific knowledge.

THE Leicester Literary and Philosophical Society, with a membership of more than three hundred, performs useful service to science in arranging a series of lectures on scientific (as well as literary) subjects, delivered by experts. In addition to these general lectures, more specialised meetings bring together members interested in particular branches of scientific work. The *Transactions* for 1929-30 (vol. 31) contain reports of these sections and an interesting address by the president, Mr. T. Kingdom, on "The Minor Legacies of Greece", in which he reviews briefly the contributions to knowledge made by some outstanding men of science among the ancient Greeks. Unfortunately, the statement of accounts shows a deficit of £15 on the year's working, but since there appears to be no entry for interest on War Stock and deposit account, there may be a hidden reserve to meet part of the loss. The Society deserves more local support, and the projected meeting of the British Association in Leicester in 1933 should give a fillip to its aims and to its membership.

MANY highly qualified translators have now been enrolled on the Aslib Panel of Expert Translators (see NATURE, June 28, p. 984). More than thirty languages are represented, from Arabic to Urdi, but the great value of the service offered by this scheme is that the members of the Panel possess that expert knowledge of special subjects without which trustworthy translations cannot be made. The range of subjects covered by the Panel is wide. Especially strong in pure and applied science, medicine, chemistry, engineering, etc., it includes also men and women experienced in law, industry, commerce, and many other branches of knowledge. Particulars of the scheme may be obtained from the Association of Special Libraries and Information Bureaux, 26 Bedford Square, London, W.C.1.

IN the article entitled "African Ethnology and Archæology" in NATURE of Nov. 1, p. 707, paragraph 2, it is stated that associated with the pottery of stone age cultures in Kenya were "tools of a Mousterian type". This phrase should read "tools of Upper Kenya Aurignacian type". Mr. L. S. B. Leakey informs us that the Upper Kenya Mousterian is contemporary with the Upper Kenya Aurignacian but is not associated with even crude pottery.

THE Year Book of the Commonwealth of Australia, of which the issue for 1929 has now appeared (Commonwealth Bureau of Census and Statistics, 5*s*.), is more than a statistical record of the country. There are many descriptive articles of considerable value, such as those on various aspects of agriculture and mineral wealth, and that on the structure and scenery of the federal capital territory. In several sections parallel figures for other countries add to the value of the statistics. The volume now runs to more than a thousand pages.

PART II. (Civil Tables) of "The Registrar-General's Statistical Review", 1929, has just been published at the reduced price of 2*s*. (London: H.M. Stationery Office). The estimated population (in thousands) of Great Britain and Ireland was 48,684. Compared with 1928, England and Wales show an increase of 0·32 per cent, Scotland and the Irish Free State decreases of 0·18 and 0·20 per cent respectively, while Northern Ireland remains stationary. Statistical data concerning marriages and divorces, passenger movements, births, and electors are included in the volume.

MESSRS. W. and G. Foyle, Ltd., 119 Charing Cross Road, W.C.2, have recently issued a catalogue of nearly 700 second-hand works relating to scientific subjects which should be of interest to many readers of NATURE.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A lecturer in engineering at the Cape Technical College—Chalmers and Guthrie (Merchants), Ltd., 9 Idol Lane, E.C.3 (Nov. 17). An assistant bacteriologist in the Public Health Laboratory of the County Council of the West Riding of Yorkshire—The Clerk of the County Council, County Hall, Wakefield (Nov. 17). A junior research assistant in the High Pressure Research Laboratories of the Imperial College of Science and Technology—The Registrar, Imperial College of Science, South Kensington, S.W.7 (Nov. 21). An agricultural chemist at the Agricultural Institute and Experimental Station, Kirton—The Principal, Agricultural Institute, Kirton, near Boston, Lincs (Nov. 22). An assistant in the Department of Pathology of the Hospital for Consumption and Diseases of the Chest—The Secretary, Hospital for Consumption and Diseases of the Chest, Brompton, S.W.3 (Nov. 22). An assistant pathologist at the Royal Surrey County Hospital, Guildford—The General Superintendent, Royal Surrey County Hospital, Guildford. A test assistant under the directorate of technical development of the Air Ministry, to assist in experimental metallurgical work—The Chief Superintendent, R.A.E., South Farnborough, Hants (quoting A.459).

Research Items.

Wastage in Imported Fruit.—Two special Reports of the Food Investigation Board, No. 38, by Dr. J. Barker, and No. 39, also by Dr. J. Barker and dealing with New Zealand apples (London: H.M. Stationery Office, 1*s*. 6*d*. and 6*d*. respectively), together with *Bulletin* No. 23 from the New Zealand Department of Scientific and Industrial Research, in which Mr. L. W. Tillar deals with the relation of storage temperature to the overseas carriage of apples, show that investigation is now actively proceeding into the many important scientific problems associated with the marketing of overseas fruit. Since 1926, with the co-operation of the Food Investigation Board, a small laboratory has been maintained near Covent Garden Market, and most of the data utilised by Dr. Barker in his more general report have been obtained through the opportunities thus provided for studying wastage, through the cordial co-operation of the Covent Garden salesmen. The problems are now seen to be many and various, but in many cases there seems to be clear indication as to the lines to follow for practical success. Thus, the condition of the fruit when gathered is seen to be of prime importance; 'bitterpit' in apples, for example—on which subject a valuable paper by W. H. Carne, H. A. Pittman, and H. G. Elliot was presented at the Imperial Horticultural Conference—can be practically avoided if the apple is picked at the rightly mature stage. New Zealand shipping experience shows the importance of prompt reduction of the temperature in the ship's hold; whilst South African experience has shown how wastage can be reduced by care and inspection during picking, the use of refrigerated trucks for long-distance rail transport, and improvement of the refrigeration systems on board ship. We are still ignorant often of the best temperature at which to maintain the fruit during transit and before sale. Also, in many cases, simple precautions such as tight packing, to avoid bruising in transit, are essential preliminaries to refinements as to temperature, ventilation, and humidity controls. The reports referred to, however, are ample evidence of the progress that has been made and of the necessity for further experimental investigation in a co-operation which extends from the orchard overseas to the retail counter at home.

Food of the Terns of the Dry Tortugas.—Mr. W. H. Longley (Year Book No. 28, Carnegie Institution of Washington, p. 288) gives some interesting observations on the food of the terns, especially the Noddy and the Sooty tern of the Bird Key Rookery, the material studied being the more or less digested fishes and squids dropped and lost by the parents when feeding their young. It is clear from these investigations that the pelagic fishes of the several hundred square miles of deep water over which the birds feed outside the Tortugas atoll provide the greater part of their food—the shallow water inshore relatively little. The chief food consists of the flying fishes *Parexocoetus mesogaster* and *Cypselurus fuscatus*, Carangids, especially *Caranx ruber* and *C. crysos*, and a variety of species belonging to various groups. Many rare forms occur in the list, some of which are new to the Tortugas. One adult *Amia* occurred and the deep water fishes *Bollmania* and *Lonchopisthus*. The little cephalopod *Spirula* is also eaten. *Coryphæna*, the 'dolphin' of these waters, also preys to a large extent on the flying fishes, but those up to six inches in length are themselves eaten by the terns, forming an important part of their food.

Mitogenetic Radiation.—Dr. Nine Choucroun (*Jour. Mar. Biol. Ass.*, vol. 17, No. 1, pp. 65-74, 1930) gives an account of experiments designed to test the validity of the hypothesis of mitogenetic radiation, formulated to account for the influence, at a distance, of dividing cells on other living tissues. Gurwitsch first observed the mitogenetic influence of embryonic tissues on the root of the onion and on yeast cells. According to him, this action, exerted only through quartz and not through glass, was due to an ultra-violet radiation, of wave-length of 2000 A., produced by the active embryonic tissues and capable of regular reflection. Dr. Choucroun exposed the developing eggs of *Echinus miliaris* to the influence of *Bacterium tumefaciens*, using as controls eggs not so exposed. He found that the observed mitogenetic influence undoubtedly exists, but, as a result of carefully designed precautions, he found that the influence could not reach Echinoderm eggs contained in flasks the stoppers of which were surrounded by a water seal. He concludes that the action of the bacterial culture on the Echinoderm eggs could not be ascribed to a radiation or to any influence acting through the walls of the receptacles containing the eggs. He believes that the observed action is the result of something material, given off by the bacterial culture and reaching the medium in which the eggs are developing, possibly as a monomolecular film which travels round the walls of the receptacles, penetrating any ordinary stopper or seal, but effectively stopped by a water seal such as he used in his experiments. He finds further evidence in support of his belief that the influence is the result of something material, in the fact that sea-water exposed first to the influence of a bacterial culture and afterwards used for Echinoderm eggs causes abnormal development of the eggs. The author, therefore, rejects the hypothesis of a mitogenetic radiation acting through the walls, whether of glass or quartz, of the receptacles in which the eggs were developing.

Northern Rotifers.—A recent part of "Die Tierwelt der Nord- und Ostsee" (Lief. 16, Teil 7.*e*: Rotatoria, von A. Remane. Pp. 156. Leipzig: Akademische Verlagsgesellschaft, m.b.H. 1929) contains a very complete and up-to-date account of the Rotifers of the North Sea and Baltic. This is a specially useful section and enables one to identify the species with ease besides learning much about the group as a whole. These tiny animals, scarcely reaching more than 2 mm. in length and usually much smaller, have always been favourites of the microscopist and one is not surprised at the large number of brackish water and marine forms recorded from these districts. They are predominantly freshwater organisms but may occur largely in water of various salinities, many being found in the sea. It is interesting to note that the order Seisonidea, containing the genus *Seison* living on *Nebalia*, possesses the most primitive characters and is purely marine, showing no trace of a freshwater ancestry. The remaining orders and suborders may occur in fresh, brackish, or sea water and it seems probable that they have mostly migrated seawards from fresh water. Here only one genus (*Zelinkiella*) is purely marine. There is a good general account of the group embracing the anatomy, reproduction, biology, and ecology, occupying about half the memoir, the remainder being devoted to the systematic part. Good keys are given, the illustrations are excellent, and the whole is recommended thoroughly to all workers in the group.

Fishes of Porto Rico and the Virgin Islands.—Mr. J. T. Nichols ("Scientific Survey of Porto Rico and the Virgin Islands." Vol. 10, parts 2 and 3. New

York Academy of Sciences, 1929) has provided a survey of the fishes of Porto Rico and the Virgin Islands, Part 2, the families Branchiostomidæ to Sciaenidæ, Part 3, Pomacentridæ to Ogcocephalidæ. This is a very useful work with a description of each species and in nearly every case a small and simple figure. Shore fishes are much the best known of the Porto Rico fauna, consisting of pelagic off-shore fishes which are for the most part cosmopolitan, and of West Indian species of the coasts, islands, and reefs from the Capes of the Carolinas to Brazil. The tropical pelagic species are usually wide-ranging surface fishes which approach tropical island shores rather freely and evidently had their origin from tropical shore forms. Of these, certain Scombriformes including *Coryphæna*, *Gymnosarda pelamys*, and various flying fishes (Exocœtidæ) are the most important. The fish fauna of these regions is very rich and all species should be easily identifiable from the present work, which not only describes and figures the species but also adds notes on distribution and in many cases on colour, feeding, and habits.

Transplant Experiments of the British Ecological Society.—A detailed account of preliminary results arising out of transplant work carried out at Potterne, Wilts, is given by Marsden-Jones and Turrill in *Journal of Ecology*, vol. 18, No. 2; August 1930. From stock plants of known homozygosity, large numbers of individuals have been obtained by cloning and selfing, and the resulting plants have been grown under carefully standardised conditions, in beds of sand, calcareous sand, clay, and chalky clay. Modifications resulting from growth under different soil conditions have been periodically recorded for *Centaurea nemoralis*, *Silene vulgaris*, *Silene maritima*, *Anthyllis vulneraria* and *Plantago major*. Of these, the first is least plastic and capable of surviving under a wide range of edaphic conditions, whilst *Anthyllis* is also non-plastic but is limited in its edaphic requirements. *Silene maritima* is more plastic than *Silene vulgaris*, which changes slowly under certain edaphic conditions. *Plantago major* is exceedingly plastic and varies between wide limits for the characters examined, namely, number of infructescences, maximum and minimum length of spike and of spike plus peduncle, on the different soils. The changes in this species, moreover, become apparent within the space of five months.

Swedish Cretaceous Mollusca and Brachiopoda.—The mollusca and Brachiopoda from the Cretaceous formation at Eriksdal, Sweden, have been investigated by R. Hägg (Sver. Geol. Undersök., *Årsbok* 23, No. 8); 130 species, including forms to which names have not as yet been given, are described and many figured. Of these, 16 gastropods, 18 pelecypods, and 1 cephalopod are new to Sweden. The geological and palæontological aspects of the containing beds are discussed, and it would appear that the Eriksdal fossils are referable to the Danian and Senonian horizons.

Neogene Shells from Japan.—Prof. Matajiro Yokoyama, to whose researches into the Tertiary molluscan fauna of Japan we have previously had occasion to refer (Cf. *inter alia*, NATURE, Aug. 24, 1929, p. 319), has now published further papers in this connexion (*Jour. Fac. Sci.*, Imp. Univ. Tokyo, sect. 2, vol. 2). From around Okuyamada, Tsuzuki county, Yamashiro province—not far from Kioto—he chronicles 37 species of Neogene mollusca, including a new species of *Umbonium*. Occasion is then taken to correct an error of determination and transfer his *Cochlioconus* from the Conidæ to the Fusidæ, as they used to be called, and place the shell in the genus *Thatcheria*. A further collection of Neogene mollusca from the southern half of the island of Karafto, or Sakhalin (Cf. NATURE, Mar. 8, 1930, p. 392), has yielded 45 species, including 5 new and some as yet indeterminate; descriptions and figures of the more important of these are given.

Length of the English Mile.—In a paper in the *Geographical Journal* for October, Sir Charles Close records some conclusions he has reached regarding the length of the old English mile as ascertained by measurements on old maps. The Bodleian map of about 1300 A.D. is the earliest detailed map of Great Britain. By comparing distances on that map, where distances between towns are marked in miles, and modern measurements, it would appear that the mile then in use was about ten furlongs. This, as Sir Flinders Petrie pointed out from a study of the same map some years ago, was about equal to the old French mile. In Lily's map of 1546 the mile was 7·4 furlongs, which was apparently the Italian mile. Mercator's map of 1564 had a mile of 9·47 furlongs. In Saxton's county maps of 1574–79 the length varied from 10·4 to 10·75 furlongs. In Speed's county maps of 1608–12 it was 10·3-10·4 furlongs on the average. In short, Sir Charles Close found out that from 1574 to 1695 the customary mile was about 10 furlongs, in spite of the statute of 1593 defining it as eight furlongs or 1760 yards.

Distribution of Earthquakes in Northern Europe.—Mr. K. E. Sahlström has recently published a valuable earthquake-map of Sweden, Norway, Finland, and Denmark (Sveriges Geologiska Undersökning, *Årsbok*, 1930). He uses a method previously applied by H. Renqvist to the earthquakes of Finland. On the map of the country, a network of points 30 km. apart is plotted. The disturbed areas of all known earthquakes from 1600 to 1925 are drawn on special maps and it is noted how many times each of these points falls within a disturbed area. Curves are then drawn through points of equal earthquake-frequency. The method thus depends on the mapping of disturbed areas rather than on the plotting of epicentres. The map shows that in northern Europe there are four principal areas of marked frequency—the fringe bordering the Gulf of Bothnia, the country round Oslo in southern Norway eastwards to Lake Vänern, the extreme west of Norway, and the west coast of Norway between the parallels of 64° and 68°. The regions free, or almost free, from earthquakes are southern Finland, Finnish Lapland, the interior of Sweden, and nearly all Denmark.

Pliocene Deposits in California.—The youngest Tertiary rocks on the south slope of the Santa Susana mountains, north of Simi Valley, California, are several hundred feet thick and consist of sandstones and conglomerates that lie unconformably on beds ranging in age from Upper Miocene to Eocene. They were examined during the course of work carried on by the 1929 summer field camp of the California Institute of Technology and the fossils collected determined and enumerated by W. P. Woodring (*Proc. Calif. Acad. Sci.*, Fourth Series, vol. 19). These fossils represent a warm-water Pliocene fauna which has been found at localities from Lower California northward to the Ventura basin and is best known as the fauna of the San Diego formation.

***Aa* and *Pahoehoe* Lavas.**—In *The Volcano Letter* for Aug. 14, 1930, a review of the *aa-pahoehoe* problem is given by G. L. Chang, with special reference to the basaltic flows of Kilauea and Mauna Loa. The rough blocky *aa* lava is due to partial crystallisation while the flow is moving rapidly. When the crust has crystallised so that it ceases to flow easily, the under-

lying current may be sufficient to break it up into a tumbled mass of blocks. The smooth, ropy *pahoehoe* lava has a chilled skin of glass. The lava below flows more slowly and the forces are insufficient to break up the smooth crust. The 1823 flow of Kilauea changed from *pahoehoe* to *aa* just as the lava reached the edge of a gentle slope and started down a much steeper incline. This sequence is usual. No flow which begins as *aa* has ever been found changing to *pahoehoe*. It commonly happens, however, that the earlier discharges of an eruption are dominantly of the *aa* type, whereas it is in the declining phases that most of the *pahoehoe* is formed. Chemically there is no significant difference between the two types, except that more iron is in the ferric state in the *aa* form. Gas is more readily released from the latter and the vesicles in consequence are very irregular in size and shape. In *pahoehoe* lava the gases are confined by the skin and the total volume of the vesicles thus tends to be greater than in *aa* lava. In the depths of both types the degree of crystallinity is alike.

Geology of Auckland, New Zealand.—A valuable study of the region south-east of Auckland City has been made by C. W. Firth (*Auckland University College Bull.* 10, Geol. Series No. 3, 1930). The Hokonui (Trias-Jura) strata were deposited in a geosyncline which then covered much of New Zealand. In early Cretaceous times the thick sediments were thrown into sharp folds and before the late Cretaceous submergence they were deeply eroded. Further erosion followed a later orogenesis, and Miocene beds are in consequence found lying on the Hokonui greywackes. Small andesitic volcanoes broke through the floor of the Miocene sea. This period of deposition was closed by the Kaikoura orogeny of the early Pliocene, and great fractures in two sets, north-west south-east, and north-east–south-west, broke up the district into blocks which were uplifted and tilted to the north-west. Great erosion and successive movements of uplift have since taken place, followed by a comparatively recent subsidence which caused the flooding of the deep, youthful valleys cut during the preceding uplift. Commencing just before this latest submergence, and continuing almost up to the present, basaltic lavas broke out and tuff and scoria cones were built up. A slight uplift of a few feet (relative to sea-level) has since occurred, but its effects on the embayed coastline of the vicinity of Auckland are almost inappreciable.

Solar Radiation at Sea.—The April–May issue of the *Bulletin* of the Polish Academy of Letters and Sciences (Mathematical Series) contains a summary of the results obtained by Dr. W. Gorczynski for the solar radiation at sea-level over the oceans he has traversed during the years 1923–28. Most of his observations were made with thermopiles and millivoltmeters, which were compared with other standard instruments from time to time. Of the 0·032 calorie per second which should be received on a square centimetre of the earth's surface if the sun were vertically over it and there were no atmospheric absorption, the atmosphere if dry absorbs and scatters 9·6 per cent, and if moist, with a humidity which is found to vary little from 80 per cent, 17·5 per cent in the North Atlantic in the latitude of the Azores and 23·7 per cent in the Indian Ocean. Absorption and scattering by dust account for a further reduction of less than 1 per cent in the North Atlantic in the latitude of the Canaries, the Gulf of Mexico, and in the Eastern Indian Ocean, and of more than 3 per cent in the Mediterranean and Red Seas. As a result, the Red Sea and the Indian Ocean get about 65 per cent, and the Gulf of Mexico, the Atlantic, and Mediterranean about 69 per cent of the possible solar radiation. On land at sea-level—for example, Bangkok—about 60 per cent is received.

The Ratio e/m for an Electron.—A determination of e/m for free electrons is described by C. T. Perry and E. L. Chaffee (in the first September number of the *Physical Review*) which, unlike other accurate measurements on free electrons, gives a value ($1·761 \pm 0·001 \times 10^7$ abs. e.m. units) in agreement with the value obtained spectroscopically. The method used was a development of the classical one of Wiechert, in which the time of passage of an electron between two points is compared with the period of a high-frequency oscillator, the electrons being driven by potentials of 10,000–20,000 volts and timed over a distance of 75 cm. in these experiments. If this result is accurate—and the measurements appear to have been made with great care—the question arises as to why earlier investigations of free electrons have led to a substantially higher value for e/m. The suggestion made by the authors, that this has been due to the effect of residual gas in the apparatus, can presumably be readily checked, and if it proves correct, will provide a welcome solution of an outstanding discrepancy.

Field-free Enclosures.—In an important class of experiments on the properties of gases at low pressures, they are subjected to bombardment by a beam of electrons introduced with known energy into an almost closed metal vessel, and the assumption is made that the whole of the interior of the vessel is at the potential of its walls. A direct test of the validity of this assumption, described by Dr. F. L. Arnot in the October number of the *Proceedings of the Royal Society*, shows that it is not accurately true. Two methods were employed. In the first, the velocities of the positive ions, which diffused out at right angles from the path of the main electron beam, were measured by a retarding field, and it was found that with the particular apparatus used, potential differences of rather more than two volts could occur in the enclosure. In the second method, the condition of the gas was analysed by a small auxiliary electrode and the results deduced from the speeds of the positive ions confirmed, and the electrons outside the main beam shown to have a random distribution of velocities equivalent to more than 20,000° abs. The potential gradient is set up by the unequal rates of diffusion of positive ions and electrons from the main beam (much as in an electrolytic concentration cell), and the method indicated for reducing it to a minimum is to work with as small a current of electrons in the main beam as is compatible with the other requirements of the experiment.

Available Phosphoric Acid in Soils.—An improved method for the determination of available phosphoric acid in soils by means of an extraction with one per cent potassium carbonate instead of the generally employed citric acid solution, has been shown by S. Das to be particularly useful in the case of calcareous soils. This new method has now been tested out on a large number of Indian soils, including acid, laterite, humus, alkali, calcareous, and non-calcareous types, all of known cropping and manurial history, and the results compared with similar estimations based on the citric acid extraction (*Soil Science*, 30, p. 33). The potassium carbonate method is shown to be equally applicable to all varieties of soil, whereas the citric acid method proved untrustworthy on alkali or calcareous types. Further, since potassium carbonate is able to extract phosphorus in organic combination in humus, which citric acid fails to do, the new method gives a truer measure of the probable fertility of the soil with respect to available phosphoric acid, and is recommended as a substitute for the citric acid methods now generally in use.

Aspects of Carbohydrate Metabolism.

II.

INVESTIGATION of the utilisation by the body of various compounds related to the sugars may be expected to throw light upon the intermediary metabolism of the carbohydrates and is, at any rate, of scientific interest. In this connexion, dihydroxyacetone, methylglyoxal, and glyceric aldehyde may be cited. Although the former antidotes insulin hypoglycæmia in both man and animals, yet, administered by mouth to human beings on a fasting stomach, it itself produces a definite hypoglycæmia (E. P. Cathcart and J. Markowitz: *Biochem. Jour.*, vol. 21, p. 1419; 1927). The fall may be compared with the secondary decrease in the blood-sugar after the ingestion of glucose, and may be due to stimulation of secretion of insulin from the pancreas. At the same time, the increased tension of carbohydrate in the liver may arrest the processes of glyconeogenesis and glycogenolysis.

In the rabbit, on the other hand, dihydroxyacetone raises the blood sugar (M. W. Goldblatt: *ibid.*, vol. 22, p. 464; 1928). In comparison with glucose this author found that dihydroxyacetone raised the respiratory quotient and increased the oxygen consumption to a greater extent but was not so effective in inhibiting the ketosis produced experimentally in man by starvation. Starvation reduces the sugar tolerance and the respiratory quotient is not raised so much as normally following the ingestion of carbohydrate. The antiketogenic influence of glucose is exerted simultaneously with the maximum increase in oxygen intake, that of dihydroxyacetone later. It appears that the latter forms glycogen less readily than glucose and cannot be considered as an intermediate stage in the breakdown of the glucose molecule. In muscle, on the other hand, W. O. Kermack, C. G. Lambie, and R. H. Slater failed to demonstrate any significant difference in the power of glucose or dihydroxyacetone to cause deposition of glycogen (*ibid.*, vol. 23, p. 416; 1929). The experiments were carried out on decerebrate, depancreated cats, in which the liver remained in circulation.

Glyceric aldehyde is another compound which may play a part in the intermediary metabolism of carbohydrate. H. G. Reeves, however, found that it was toxic to the isolated heart of the rabbit, although it could augment and accelerate the beat of the frog's or toad's heart (*Quart. Jour. Exp. Physiol.*, vol. 18, p. 277; 1927). It is possible that the difference between the mammalian and amphibian hearts is due to the difference in the temperatures at which the perfusions are necessarily carried out. It appears, therefore, that, at any rate in mammals, glyceric aldehyde is not an intermediate in the utilisation of glucose by cardiac muscle.

Goldblatt has found that carbohydrate metabolism is seriously interfered with in man by the administration of alkali, with the consequent production of a state of alkalosis (*Biochem. Jour.*, vol. 21, p. 991; 1927). Glucose by mouth now increases the blood-sugar to a greater extent than normally and some is excreted in the urine; at the same time the rise in the respiratory quotient is less marked. These results indicate that both the storage and oxidation of carbohydrate are depressed. Similarly, alkali decreases the response of the rabbit to an injection of insulin, as well as the deposition of glycogen in the liver and muscles of the rat.

A considerable amount of work has been carried out on the carbohydrate metabolism of isolated tissues. G. S. Eadie has examined the conditions of action of rat's liver amylase (*Biochem. Jour.*, vol. 21, p. 314; 1927). The enzyme was obtained by drying the organ with acetone and extracting the powder with 50 per cent. glycerol, afterwards filtering and dialysing the extract. It was found that the liver enzyme was contaminated with blood amylase unless the organ was first perfused with Ringer's solution. The optimum pH of liver amylase is at 6, whilst that of blood amylase is at 6·8–6·9. The optimum salt concentration is 0·1 per cent; addition of adrenaline has no effect upon its activity. The enzyme and its substrate glycogen coexist in the same cell. E. F. Lesser (*ibid.*, p. 1128) considers that the amylase is to a large extent adsorbed upon surfaces within the cell and so unable to act upon the glycogen.

J. T. Irving has investigated the glucose metabolism of kidney tissue *in vitro* (*Biochem. Jour.*, vol. 22, p. 964; 1928). In the presence of oxygen, but not in its absence, chopped cortex incubated in phosphate or carbonate buffer converts glucose to lactic acid together with a small amount of hexose diphosphate; at the same time glycogen is utilised. The mechanism is therefore different from that found in muscle.

E. G. Holmes has continued his researches upon the metabolism of nervous tissue (*Biochem. Jour.*, vol. 23, p. 1182; 1929; with C. A. Ashford, *ibid.*, p. 748; with R. W. Gerard, *ibid.*, p. 738; and with M. Sherif, *ibid.*, vol. 24, p. 400; 1930). In the case of brain it was found that free phosphate was liberated on both anaerobic and aerobic incubation, in the presence or in the absence of glucose; no evidence of the synthesis of hexose phosphate in the process of formation of lactic acid was obtained, although the tissue can perform this operation to a small extent. Sodium fluoride inhibits this liberation of phosphate, when present in high concentration; even low concentrations markedly inhibit the formation of lactic acid, so that the two processes appear to be independent; in fact, it was found that lactic acid is freely formed from glucose in the absence of phosphate and its addition does not increase the velocity of formation of the acid. Brain tissue forms less lactic acid from glycogen than from glucose; sodium fluoride inhibits both phosphate and acid production, and removal of phosphate stops the formation of acid. It appears, therefore, that there are two lactic acid mechanisms in brain: one, quantitatively the more important, involves glucose and is independent of phosphate; the other involves glycogen and depends on the availability of phosphate. The source of the phosphate in the former case is obscure.

On anaerobic incubation, mammalian nerve produces lactic acid, two-thirds of which come from the free carbohydrate of the tissue and one-third from glycogen; in oxygen, no lactic acid is formed, but there is a definite fall in the free carbohydrate. Preformed lactic acid is not removed in oxygen (as is the case with brain and muscle). The oxygen consumption of nerve is much less than that of brain; about 60 per cent of the resting metabolism can be accounted for by the observed oxidation of carbohydrate. These carbohydrate changes apparently play no part in the extra metabolism of stimulation, since the nerve will still give a response after disappearance of all the carbohydrate. As the carbohydrate is consumed the oxygen consumption of resting nerve decreases; in the presence of small amounts of glucose or galactose, however, the consumption remains linear for several hours; brain, on the other hand, does not apparently use galactose.

The chemical composition and metabolism of non-

medullated nerve are different from those of medullated; for these experiments Holmes used the nerves of crabs. The free carbohydrate, and especially the glycogen content, is very much higher; the latter may form 20 per cent of the total solids. Under anaerobic conditions at rest, the glycogen decreases, with a coincident increase in the free carbohydrate and lactic acid; in oxygen the fall in glycogen and the rise in free sugar are considerably less, and there is no increase in lactic acid, although preformed lactic acid is not removed. In the nerve-ganglia the presence of a polysaccharide was detected.

J. Pryde and R. W. Humphreys (*Biochem. Jour.*, vol. 20, p. 825; 1926) have shown that the oxidic bridge of the galactose in the cerebrosides of ox brain is of the stable amylene type.

The carbohydrate metabolism of cancer cells differs from that of most normal tissues in that aerobic glycolysis is a prominent feature, whilst the oxidative removal of lactic acid is a relatively slow process. B. E. Holmes (*Biochem. Jour.*, vol. 20, p. 812; 1926) has shown that certain tumour tissues contain very little reduced glutathione and have only a slight activity in reducing the oxidised form when added. H. G. Crabtree (*ibid.*, vol. 22, p. 1289; 1928) has found that certain pathological overgrowths, aroused by different viruses, behave like malignant tissue in their carbohydrate metabolism; this change from the normal was not seen when the virus failed to produce hyperplasia.

F. Dickens and F. Šimer (*Lancet*, vol. 2, p. 10; 1930) have recently shown that the respiratory quotient of normal tissues runs parallel with their power of anaerobic glycolysis; tumours have a low respiratory quotient, indicating a poor ability to oxidise carbohydrate, although actively glycolytic. The inability to oxidise lactic acid is peculiar, since tumours, like normal tissues, oxidise pyruvic acid.

S. T. Harrison and E. Mellanby (*Biochem. Jour.*, vol. 24, p. 141; 1930) have investigated the inhibitory action of pancreatic and other extracts upon the formation of lactic acid in cancer and muscle. It has been known for some time that pancreatic extracts inhibit acid production by muscle hash. D. R. McCullagh (*ibid.*, vol. 22, p. 402; 1928) confirmed this for muscle extract; he also showed that the former prevented the disappearance of carbohydrate, but caused an increase in the free phosphate content instead of a decrease. In the presence of sodium fluoride, pancreatic extract prevented the formation of hexose phosphate, and the author considers that this is the cause of the failure to produce lactic acid. In a later paper, working with E. M. Case, it was found that the inhibition was probably due to the amylase present in the pancreatic extract (*ibid.*, p. 1060).

The properties of the unknown factor and the enzyme are very similar: inhibition is observed when malt or taka diastase replaces the pancreatic extract, or when glycogen is used as substrate instead of starch; and the formation of lactic acid from activated glucose by muscle extract is not inhibited. Harrison and Mellanby confirmed the inhibition when starch is used as the source of the lactic acid, and the failure of inhibition with glucose; they also found, however, that inhibition occurs with hexose diphosphate but not with hexose monophosphate. They therefore consider that the pancreatic extract does not act by inhibiting the esterification of hexose but by forming maltose, which is only slightly acted upon by the muscle system with the production of lactic acid. They agree that the inhibition is due to amylase; the inhibition of lactic acid formation from hexose diphosphate, however, cannot yet be explained. The same authors have also shown that various preparations of amylase inhibit the glycolysis, anaerobic and aerobic, of tumour tissue; the latter cannot form lactic acid from hexose di- or mono-phosphate or from starch to any appreciable extent, so that in this case also the inhibition cannot be due to inhibition of ester formation.

Pancreatic extracts have also been reported to contain an antiglyoxalase. Phenylglyoxal is converted to mandelic acid by liver extract; pancreatic extract inhibits the reaction. J. O. Giršavičius (*Biochem. Jour.*, vol. 24, p. 446; 1930) has found that pancreatic extract itself produces acid from phenylglyoxal; a reaction appears to occur between the phenylglyoxal and diamino-acids and polypeptides in the extract with production of an orange substance. It does not appear that this reaction can be responsible for the antiglyoxalase activity of pancreatic extracts, since the substances involved are thermostable and dialysable.

Mosses as Epiphytes.*

WISNIEWSKI has surveyed parts of the virgin forest of Bialowieza, with special reference to the epiphytic Bryophyta. His results and the discussion of their significance bring out several points of interest bearing on the nature of epiphytism in this group. He recognises four associations of mosses on the trees, the first two of which appear to be true epiphytes, whilst the other two are more closely related to the vegetation of the ground flora.

The two epiphytic associations are:

(1) On broad-leaved trees (except *Betula* spp.): *Leucodon sciuroides* (chiefly on *Carpinus betulus*) and *Anomodon viticulosus* (chiefly on *Acer platanoides* and *Fraxinus excelsior*).

(2) On coniferous trees and *Betula* spp.: *Drepanium* (*Hypnum*) *cupressiforme*, var. *filiforme* and *Orthodicranum montanum*.

The other two associations under consideration are: (3) In damper situations on any type of tree: *Eurhynchium striatum*.

(4) In drier situations on any type of tree: *Pleurozium Schreberi*.

Considering possible factors influencing the ability of mosses to grow in different situations, it is clear that neither light nor temperature is a limiting factor. The light intensity lies well within the limits at which at least some of the species under consideration have been found to flourish, according to the work of Zmuda and Malta, and the same applies to the temperature range. The question of water supply is, however, a vital one for mosses as their method of water absorption is entirely different from that of root-bearing plants. It is clear from the work of Schimper and others that the rhizoids of a moss are ineffective in the uptake of water, for even if the lower parts of a moss plant are actually in water, the upper parts may be seen to wilt. The chief method of water absorption seems to be imbibition by the walls over the whole surface of the plant, whether dead or living, as is illustrated by the rapid recovery of form on moistening dry specimens. Wisniewski found an interesting difference in this respect between the epiphytic mosses and those of the ground flora, for whilst the dry plants of the former group

* Wisniewski, T. "Les associations des Muscinées (Bryophyta) épiphytes de la Pologne, en particulier celles de la forêt vierge de Bialowieza." (*Bull. Internat. de l'Acad. Polonaise des Sci. et des Lettres*, pp. 293-342; 1929.)

recovered either instantaneously or at most after a few seconds on moistening, those of the latter took 40-50 sec., or often longer.

Müller points out that mosses cease to condense atmospheric moisture when the tension of water vapour is lower in the air than in the cells, so that this method is of significance to the moss only at times when the atmosphere approaches saturation. In the forest, the saturation deficit of the atmosphere increases with the distance from the ground level, and the rate of this increase depends chiefly upon the permeability of the soil and the type of forest (that is, broad-leaved or coniferous). Partly as a result of this, the moss life of the *Leucodon* and *Anomodon* type in the broad-leaved forest extends up the trees to a height of 20 m., whilst the *Drepanium* and *Orthodicranum* type in the coniferous forest only extends 3-4 m. The heights to which the mosses can extend is evidently controlled to some extent also by properties of the mosses themselves, since only certain species—the epiphytic species—can extend up the tree more than about 30-50 cm.; below this level one finds some of the species characteristic of the ground flora, for example, *Eurhynchium striatum*, *Pleurozium Schreberi*, along with certain Phanerogams, such as *Oxalis acetosella* and *Geranium Robertianum*.

The general occurrence of certain epiphytes on broad-leaved and others on coniferous trees might be explained to some extent by the humidity of the type of forest formed by such trees, a factor which is seen to influence the flora of the undergrowth and tree bases. There is, however, something more than this obvious relationship between the true epiphytic mosses and their hosts, for one finds that trees of a particular kind, for example, *Pinus sylvestris*, have their characteristic epiphytic mosses whether growing in a typical pine association or occurring as an isolated example in an association consisting typically of broad-leaved trees, and vice versa. Further, one finds that within an association, a particular moss may show a preference for a particular kind of tree, for example, *Leucodon* for *Carpinus betulus* and *Anomodon* for *Acer platanoides* and *Fraxinus excelsior*—a curious fact which future investigation may show to be associated with the type of bark (fissured or scale) and the consequent difference in the rate at which water flows away.

An unexpected feature that is without any explanation is that, as regards epiphytic moss vegetation, *Betula* spp. are classed with the conifers—a fact which is further supported by the distribution of epiphytic lichens by Räsänen in Finland.

The connexion between an epiphytic moss and its host cannot be regarded as strict, by any means. Wisniewski points out that, although the types he regards as epiphytic are rarely found in other habitats, there are very few of them which have not been recorded as growing on rock or stone as well. The marked preference for the epiphytic habit is further emphasised by the fact that very few of them are recorded from altitudes or latitudes beyond the tree zone. A study of the literature on moss distribution brings out the fact that the majority of the epiphytic forms—48 per cent—of the Bialowieza forest are holoarctic in distribution, extending across Europe to North Asia and China on one side, and to North America on the other. It is curious to find that of the twelve species of trees serving as the commonest hosts for epiphytic mosses in the Bialowieza forest, none occurs in North America, so that evidently the same species of mosses in the latter continent must have transferred to other hosts.

World Geometry in its Time Relations.

PROF. R. C. TOLMAN, of the Norman Bridge Laboratory of Physics, Pasadena, has published, in recent issues of the *Proceedings* of the U.S. National Academy of Sciences, a series of papers on world geometry in its time relations. The subject is the same as that of recent papers by Lemaître, de Sitter, and Eddington, namely, the existence of non-static solutions of Einstein's gravitational equations. Prof. Tolman's papers are admirably concrete and free from paradox, and will appeal to those who are attracted by a certain definiteness of point of view.

After discussing the recognised weaknesses of the Einstein line-element (full, static universe) and the de Sitter line-element (empty universe), Prof. Tolman proceeds to determine a line-element on the basis of five assumptions: (1) spatial spherical symmetry; (2) symmetry with respect to past and future time; (3) a criterion of stability; (4) and (5) conditions of isotropy with respect to the volume defined by a system of nebulæ and with respect to the average density of matter. These conditions are shown to determine the form of the line element uniquely save for a certain function of time only, which occurs as a multiplier in the space part of the line element. As a first approximation, Prof. Tolman takes this to be a linear function of the time, and reduces its determination to the ascertaining of the numerical value of a single parameter, which must be a physical constant. This constant can be interpreted in terms of the time-interval between the sending out of two light-impulses by a nebula and the time-interval between their receptions. If these are not equal, the nebula will appear to be in motion in the line of sight, and the lines in its spectrum will be displaced with red or violet. The discrepancy between the two intervals will increase with the distance of the nebula, and Prof. Tolman deduces a proportionality between distance and line-displacement. This is in agreement with the empirically found relation between red-shift and distance for nebulæ, and, using the observed numerical values, the author infers the values of the constant in his formula for the line-element.

Prof. Tolman then shows that owing to the presence of this time-factor in the line-element, the mass enclosed within a given volume must be changing, and he identifies this change with the transformation of matter into radiation—that is, he identifies the reduction in measured mass with the mass disappearing from the volume in the form of radiation. The value of the time-constant deduced from the observed recession of nebulæ should thus be connected with the rate of evolution of energy per gram by the stars. From the nebular recession, Tolman finds $k = 5{\cdot}1 \times 10^{-10}$ (years)$^{-1}$, whilst the values of k deduced from the observed masses and luminosities of the stars as tabulated by him vary from $1{\cdot}7 \times 10^{-10}$ down to $2{\cdot}3 \times 10^{-16}$.

In a later paper of the series Prof. Tolman shows that the addition of higher terms to his linear approximation for his undetermined function of time may seriously modify the values of k deduced from the observed rate of annihilation of matter, and concludes that the discrepancy is not fatal. One is naturally tempted to make the criticism that the rate of annihilation of matter must be governed by the physics of the energy-generating process in stars, and so is surely a different physical phenomenon from the recession of the nebulæ, implied by such considerations as those of stability and symmetry in the universe. This, however, is not incompatible with the view that the transformation of matter is the

primary process, and that this by conditioning the mass-change of the universe is the 'cause' of the world-geometry which predicts the nebular recession.

The same confusion between perhaps diverse physical phenomena is seen in another paper of the series, where Prof. Tolman gives an actual formula for the luminosity of a nebula in terms of its distance and red-shift. This appears to assume some common property in the nebulæ, but it is obvious that nebulæ (like stars) could have intrinsically different luminosities for the same distance. The whole discussion is, however, most stimulating, and will certainly help to provoke more accurate and extensive observations of the most distant nebulæ.

Thinning Operations in Forestry.

FOR a century or two it has probably been the desire and aim of the scientific forester to endeavour to bring the work of thinning a wood, at various ages in its development, within the circumscribed limits of a definition. There are many experienced foresters, and probably some of the most expert in this part of the forester's work, who maintain that any definition of the work involved or the laying down of any hard-and-fast rules is impracticable—if for no other reason than that in any wood the soil and other factors vary from place to place, with a consequent variability in growth. It follows from this state of affairs that the thinning operations must, if properly carried out, be based upon the condition of the individual trees and their crowns at any spot; and this condition will be a variable quantity. Greater regularity may be found in well-managed coniferous woods, and even in young well-grown broad-leaved crops; but so far as the forests of the British Empire are concerned, such conditions are only exceptionally present.

Some of these points are recognised in the brochure entitled "Classifications of Thinnings" (*Indian For. Records*, vol. 15, pt. 1, 1930. Govt. of India, Calcutta Press). One of the reasons for the persistent effort to evolve some method of classifying thinnings has been the desire to have some rules or rule-of-thumb methods of dealing with certain types of crops which would be simple enough in practice to enable their carrying out by the subordinate staff. In view of the enormous and increasing amount of this type of work which faces the numerically small staffs of the Empire Forestry Departments, it will prove almost a necessity to place a portion of the thinning work in the hands of the non-gazetted grades. But it has long been accepted that the best amongst thinning experts are born with the gift; that such are to be found in the lower ranks as well as in the upper. In either case the young forester requires to be trained by the senior who is an expert in practice, and not by any rule of thumb such as the brochure here under review attempts to prescribe.

This is not to say that the attempted classification is not of use to those who have a first-hand practical acquaintance with thinning work, either in one type of crop (mixed or pure), or in varying crops managed under different sylvicultural systems. But a very considerable amount of experience would be required before this attempt at classifying thinnings could be translated into practice: even then a wide and varying meaning can be given by different performers to the definitions given under the subdivisions on "Intensity of Thinnings". These subdivisions speak for themselves (for the definitions the pamphlet must be consulted). I. Ordinary Thinning: (1) Light thinning (A grade): (2) moderate thinning (B grade); heavy thinning (C grade); very heavy thinning (D grade). II. Crown Thinnings: (1) Light crown thinning (L.C. grade); heavy crown thinning (H.C. grade). To make use of this brochure with intelligence, and without danger to the crops being treated, the forester requires to possess a clear knowledge of the relative significance of the words and phrases used in the definitions, combined with a very considerable previous practice in the carrying out of one of the most important and interesting of his duties.

Curious Markings on Stones in Scotland.

THE *Glasgow Herald* of Sept. 17 contains an article by Mr. L. MacLellan Mann describing the markings on some stones at Langside and Cleuch, near Glasgow. The markings on the two stones are nearly alike, consisting of series of rings, arcs, and cup-like depressions. Mr. Mann claims that these have astronomical significance; some of the groups of cups are shown to resemble the Sickle in Leo and (more doubtfully) a star-group in Scorpio. He further claims that he can identify records of ancient eclipses; it would, however, need a fuller explanation of his method to induce astronomers to accept his claims in full. He states that he identified the date of a recorded eclipse as B.C. 2983 Mar. 28* Gregorian reckoning from the stone itself, and afterwards found by consulting astronomers in Berlin that there was a total eclipse on that date, the track of totality passing over or near Glasgow. The writer of the present note has verified this latter fact independently, making use of the new-moon tables by the late C. Schoch that are contained in "The Venus Tablets of Ammizaduga" (Langdon and Fotheringham, 1928). These tables make use of the latest values of the solar and lunar accelerations; but there is of necessity a considerable margin of uncertainty in computing the tracks of very early eclipses.

This eclipse affords a good illustration of the use of M. Oppert's long eclipse cycle of 1805 years; the name 'megalosaros' has been suggested for it; it is about a hundred times as long as the 'saros', and shares with it the useful property that the parallaxes of sun and moon nearly repeat themselves. The following table gives the tracks of the three successors of this eclipse; they are from Oppolzer's "Canon" and Schrader's sequel to it:

Date.	Sunrise Point.		Noon Point.		Sunset Point.	
2982 April 21 6			47 W.			
1177 April 16·43	41 W	1 N.	20 E.	40 N.	99 E.	58 N.
628 April 10·03	99 E.	9 N.	161 E.	51 N.	104 W.	63 N.
2433 April 20 46	50 W.	6 N.	13 E.	48 N	106 E.	56 N.

The first three dates are by the Julian calendar, the fourth by the Gregorian one.

It will be seen that the cycle enables us to make a close approximation to the latitude of the eclipse track; the longitude offers greater difficulty owing to the large effect of the secular acceleration in such a long period. Oppolzer's older eclipses themselves require a considerable shift in longitude to reduce to Schoch's values of the accelerations.

Mr. Mann claims to have found similar records of still older eclipses; thus he refers to one in New Mexico of the date B.C. 3457 Sept. 5. It would, however, be well for him to make the full case for the 2983 eclipse accessible to astronomers before asking them to consider these more remote ones.

* Mr. Mann gives Mar. 27, but 28 appears to be correct.

University and Educational Intelligence.

CAMBRIDGE.—The title of Girdlers lecturer in economics has been conferred on Mr. G. F. Shove, of King's College. Mr. H. H. Nicholson, of Selwyn College, has been appointed University lecturer in agricultural chemistry.

The following elections have been announced:—To an Isaac Newton studentship, founded for the encouragement of study and research in astronomy and physical optics, value £250 a year for three years: R. van der Riet Woolley, of Gonville and Caius College, formerly of the University of Cape Town, who was a wrangler with mark of distinction in the Mathematical Tripos of 1928; to additional Isaac Newton studentships, tenable in each case for one year: V. V. Narliker, Non-Coll., and L. C. Young, Trinity.

At the annual general meeting of the Cambridge Philosophical Society held on Oct. 27, Prof. F. J. M. Stratton was elected president, and the following new members of the council were elected: Mr. J. W. Landon, Dr. E. D. Adrian, Mr. F. Debenham, and Mr. W. R. Dean.

NOTICE is given by the Chemical Society that applications for grants from the research fund of the Society must reach the assistant secretary, on prescribed forms, by at latest Dec. 1. Applicants are reminded that the income arising from the donation of the Goldsmiths' Company is to be more or less especially devoted to the encouragement of research in inorganic and metallurgical chemistry, and that the income from the Perkin Memorial Fund is to be applied to investigations relating to problems connected with the coal tar and allied industries.

THE Association of University Teachers has as one of its objects the promotion of exchanges of opinion not only between the universities of Britain but also between them and the universities of other nations. To further this aim, a short visit to French universities was recently organised with the cordial and very efficient help of M. Desclos, of the Office National des Universités et Écoles françaises. Fifteen members of the Association took part in the visit, which embraced the three universities of Paris, Lille, and Dijon. A report of facts elicited in the course of their investigations, with an account of some of their impressions and inferences, is published under the title "The French University System" in the October number of *The Universities Review*, issued by the Association, price 2*s*. This gives, in thirty pages, an informative and interesting conspectus of the university in relation to the State; the relation of the university to the general system of education; the university in relation to the cultural and economic life of France and other countries; the constitution and establishment of the university; university finance; staffing; student life and work; and courses and examinations. The report brings out some instructive comparisons and contrasts. At the head of each of the seventeen regional units, known as 'académies', in which the administration of public instruction in France is organised, stands the 'Recteur de l'Université'. Of this functionary the report observes that his duties comprise those of vice-chancellor, principal, president, and treasurer of the university, and in addition those of local director of education, member of the university grants committee, and official of the board of education. "Formidable and even autocratic as the authority of the Recteur may appear to be, we found that university dependence on the State entailed far less sacrifice of educational freedom than we were inclined to expect."

Historic Natural Events.

Nov. 9, 1883. Brilliant Sunset in England.—About ten minutes before sunset, the sky being very clear and a deep blue except for a few fleeces of cirro-cumulus nearly overhead, the sun turned unusually white and descended in a slight haze, with curious greenish white and yellowish white opalescence in the upper part. About 15 minutes after sunset the sky turned a brilliant but delicate pink, beneath which a shining green and white opalescence hung like a luminous mist. The effect grew with increasing darkness, and lit up the landscape, although the moon was shining brightly. The horizon, remained deep red until nearly 6 P.M. These remarkable sunsets, and similar effects at sunrise, were visible throughout the winter, and were due to the dust thrown into the air by the explosive volcanic eruption of Krakatoa, on Aug. 26–28, 1883.

Nov. 11, 1099. Storm in the North Sea.—A violent storm at high tide flooded the coasts of Holland and England as far as Kent, including the Thames Estuary. It is said that 100,000 persons lost their lives.

Nov. 11, 1572. Nova Cassiopeiæ.—On this date, Tycho Brahe at his observatory at Uraniborg saw that a new star, surpassing the other stars in brilliancy, had appeared in the constellation Cassiopeia. At first the nova was as bright as Venus at its maximum brightness and could be seen by keen-sighted people near midday. It then slowly declined, but in February and March 1573 it was still as bright as the first magnitude stars; by February 1574 it had reached the sixth magnitude, and by the end of March it ceased to be visible to naked-eye vision. There were accompanying changes in the colour of the nova—from white to yellow, then to a reddish hue, and lastly it became "like lead, somewhat like Saturn". Measurements of its position convinced Tycho Brahe that "this star is not some kind of comet or a fiery meteor . . . but that it is a star shining in the firmament itself—one that has never previously been seen before our time, in any age since the beginning of the world". Pliny records that Hipparchus is said to have observed a new star; since that of 1572, there have been thirteen bright novæ discovered, the most notable being those of 1604, 1901, and 1918.

Nov. 12, 1236. Inundations in East of England.—The sea burst out with such high tides and tempests of wind that the marsh countries were drowned and overflowed, and great herds and flocks perished, besides many persons. The sea rose continuously for two days and one night without ebbing, owing to the great violence of the wind. At Wisbech and neighbouring villages many people were drowned, one hundred in one village.

Nov. 14–15, 1574. Aurora.—Stow records in his "Annals" that there "were seen in the Air strange Impressions of Fire and Smoak to proceed forth of a black Cloud in the North towards the South . . . the next Night following, the Heavens from all parts did seem to burn marvellous ragingly, and over our Heads the Flames from the Horizon round about rising did meet, and there double and roll one in another, as if it had been in a clear Furnace".

Nov. 14, 1854. "Balaclava" Storm.—The British and French fleets and transports lying outside Balaclava Harbour, in the Black Sea, were wrecked and scattered by a violent gale, accompanied by rain which afterwards turned to snow. The loss of stores caused intense suffering among the allied troops in the severe winter which followed. The course of this storm across Europe was afterwards studied by the

French astronomer Leverrier, as a result of which he organised the international exchange of telegraphic weather reports and the first storm-warning service in Europe.

Nov. 14, 1866. Meteor Shower.—The occurrence of notable meteor showers in November 1799 and in November 1833 led to the prediction of a recurrence on a similar scale in 1866 on Nov. 14. Expectations were realised and a shower began about 11 P.M. on Nov. 13, culminated in a wonderful display between 1 and 2 A.M. on Nov. 14, and died away about 4 A.M. As the shower progressed, the radiant point in Leo was ascending above the eastern horizon. In brightness great numbers of the meteors equalled first magnitude stars, many were as bright as Jupiter, and some exceeded Venus at its brightest. It was estimated from systematic counts made by observers that at the height of the display about 6000 meteors were seen in one hour.

Nov. 14, 1923. Floods in Northern England.—On Nov. 12 and 13 a deep barometric depression passed north of Ireland and across Scotland along the line of the Caledonian Canal. The south-westerly gales in Lancashire were associated with heavy rains on the Pennines. On Nov. 14 the Mersey overflowed its banks, the floods at Sale being the most severe on record. At Sale Priory the water was 11 ft. deep, at Clitheroe 300 houses were flooded, and at Bury fire engines had to be called to pump the water out of houses.

Nov. 15, 1905. Aurora Borealis.—A remarkable display of aurora borealis was seen in all parts of the British Isles between 6 and 9.30 P.M. At Epsom, according to Mr. Spencer Russell, it first became visible in the north at 7.30 P.M., a narrow arc of pale yellow spanning the horizon. "Frequent displays of rays and streamers were noticed rising and falling rapidly from the arc, their colour varying from pale pink to a blood-red crimson. By 8.55 P.M. the aurora had extended considerably and was of an irregular form, a most noticeable feature being the variability in colour, fading at times to a pale subdued pink, brightening up with a peculiar twitching movement to a deep crimson." The display was very brilliant in the west of Europe—so much so that at Ghent and Turnhout in Belgium alarms of fire were raised. It is noteworthy that in Scotland the aurora appeared to the south of the zenith, in southern England to the north.

Societies and Academies.

PARIS.

Academy of Sciences, Sept. 29.—**E. L. Bouvier**: A new type of ceratocampian Saturnioid.—**Mlle. Marie Charpentier**: The Peano points of a differential equation of the first order.—**Paul Montel**: Some consequences of Rolle's theorem.—**A. Rosenblatt**: Linear equations with total differentials.—**Miron Nicolesco**: The extension of the theorem of Gauss to harmonic functions of p order.—**Podtiaguine**: The upper limit of the canonical product of infinite order.—**L. Escande** and **M. Teissié-Solier**: The chronophotographic study of the flow [of a fluid] round a plate normal to the current. The velocity measured on the surface of discontinuity is constant and equal to the velocity at infinity, agreeing with that indicated by theory. The velocities found experimentally at various points give a law of retardation in good agreement with the theoretical law.—**L. Goldstein**: The principle of exclusion and intramolecular statistics.—**Pierre Chevenard** and **Albert Portevin**: The secondary tempering of hyper-tempered steels and the stability of austenite.—**Jean Lugeon**: Simultaneous investigation by atmospherics at Zurich and in the Sahara. On the basis of three years' records, the following conclusion can be drawn: out of every 100 atmospherics recorded in a year, 20 per cent are of distant origin, some thousands of kilometres; 70 per cent have a range of between 100 and 1000 kilometres; 10 per cent are local, with a range of less then 100 kilometres. The Kennelly-Heaviside layer is always higher at El-Golea (Sahara) than at Zurich. **Jean Piveteau**: Contribution to the study of the fossil Ganoid fishes: the family of the Catopteridæ.—**Louis Baudin**: The variation of the respiratory exchanges of fishes as a function of the barometric pressure. By experiments at Lausanne and at Concarneau it has been established that fish are very sensitive to changes in the barometric pressure, and this sensibility is measured by large differences in the gaseous exchanges and in the respiratory coefficient.

Oct. 6.—The president announced the death of Paul Wagner, *correspondant* for the Section of Rural Economy. **J. Costantin**: The phytopathological guarantees of non-degenerescence of the potato in North America. Since 1922 the author has recommended the use of seed potatoes collected in cold countries or in the mountains. Further support of this view has been obtained from results in America and Canada. The climate probably acts in limiting the extension of disease, in facilitating the selection of healthy individuals, and perhaps in suppressing disease. **Paul Helbronner**: The polar aurora of Sept. 3, and on its action on radio-telegraphic transmissions. A list of wireless communications interrupted by this aurora is given. **Léon Guillet, Jean Galibourg**, and **Marcel Ballay**: Thermal treatment hardening grey cast irons.—**E. Bataillon** and **Tchou Su**: The reaction peculiar to the egg in *Hyla*. Perivitelline and infertility of the hydrated virgin material. **A. Buhl**: Wave geometry. Propagated waves and integral invariants.—**P. Rachevsky**: Sub-projective spaces.—**B. Kagan**: Sub-projective spaces. **H. Chapiro**: Sub-projective spaces.—**V. Romanovsky**: A class of linear integral equations.—**Mezin**: The kinematics of the elements of lines and surfaces applied to meteorology. **E. Coupleux** and **Givelet**: An electric organ. An outline of an entirely new type of instrument, based on the triode valve.—**A. Bogros**: The saturated vapour pressure of lithium. **Charles Platrier**: The broadcasting in France of the landing of the aviators Costes and Bellonte in the United States.—**Nicolas G. Perrakis**: The influence of the developer on the properties of a photographic plate. A quantitative study of the action of two different developers, other variables being maintained as constant as possible.—**A. Kastler**: The Raman effect in liquids possessing rotatory power. The molecular asymmetry shown in the transmission of light (rotatory power) and in its absorption (circular dichroism) does not appear in the Raman diffusion spectra.—**A. P. Rollet** and **L. Andrès**: The alkaline pentaborates.—**J. Fromaget** and **J. H. Hoffet**: The extension of the littoral facies of the upper Devonian and the palæogeography of northern Indo-China. **E. Saurin**: The existence of post-Lias granites in Cochin China and South Annam.—**A. Loubière**: The intramedullar vascularisation of the Trigonospermales.—**Ad. Davy de Virville**: The existence of an unnoticed zone of vegetation on the coast of the Armorican massif: the *Caloplaca marina* zone.—**H. Lagatu** and **L. Maume**: The explicit reply of leaf diagnosis when other means of observation fail.

LENINGRAD.

Academy of Sciences (*Comptes rendus*, No. 7, 1930). — **G. Krutkov**: A problem of the theory of perturbations.—**S. Sobolev**: The wave equation in the case of a heterogeneous isotropic medium.—**A. Mordvilko**: Aphids of the tribe *Hormaphidina*. General considerations on the relationships and life histories.

A. Tolmačev: A new species of *Draba* from northern Siberia. Description of *D. prozorovskii* sp. n., from the river Khatanga.—**E. Kozlova**: Bionomics of *Pratinocola insignis* Blyth. This species nests in the subalpine zone of the Khangai mountains, northern Mongolia; nest and eggs are described, and notes on the colour of nesting birds are given.

Comptes rendus, No. 8, 1930. **F. Loewinson-Lessing**: The delimitation of liparites from dacites. The percentage of silica is a less reliable character than the acidity coefficient. **R. Kuzmin**: The Diophantine approximations of algebraic irrational quantities.—**A. Andronov** and **A. Witt**: Inconstant periodic movements and the theory of multivibrators of Abraham and Bloch.—**V. Česnokov** and **E. Bazyrina**: The factors limiting photosynthesis. The intensity of light and the carbon dioxide concentration are not direct factors limiting the photosynthesis; the actual limiting factor is the velocity of the penetration of carbon dioxide through the protoplasm, and this velocity increases with the intensity of light and with the concentration of the carbon dioxide.—**D. Gerasimov**: Distinctive characters of the pollen of *Larix* and *Pinus cembra* in turf. The main difference is the structure of the air-sacs.—**P. Schmidt**: The Pacific halibut, *Hippoglossus hippoglossus* L., of the Atlantic, does not occur in the Pacific, and is replaced there by *Hipoglossus stenolepis* Schmidt.

MELBOURNE.

Royal Society of Victoria, Sept. 11.—**John Clark**: A new species of Lymexylionidæ (Coleoptera). Under the name of *Atractocerus crassicornis*, a new species is described and figured, together with the remarkable elongated, slender larvæ. A résumé was given of the habits of the beetle and larvæ. The latter are usually regarded as pin-hole borers and cause extensive damage in growing trees, particularly Eucalypts, in Australia.

ROME.

Royal National Academy of the Lincei, May 18. — **G. Scorza-Dragoni**: A problem on the partial maxima and minima of a function.—**D. Montesano**: The normal descendencies of geometric Cremonian groups (1).—**G. Nicoladzé**: A general method of investigating the invariant properties of geometric figures.—**E. Čech**: A demonstration of Cauchy's theorem and of Gauss's formula.—**M. Maggini**: The spectral type of the components of a double star, determined by means of the interferometer. Determination of the colour indices and hence of the spectral type of the components of a double star by measuring the visibility of the fringes, is described. —**G. Viola**: Circular orbit of U Cephei.—**G. L. Andrissi**: The system 61 Cygni. The existence of an orbital motion of the two components of 61 Cygni, first proved by Schlesinger, and hence that of a physical connexion between these components, are confirmed.—**A. Baroni**: Action of magnesium ethyl bromide and of oxidising agents on diethyl polysulphides. The action of magnesium ethyl bromide on diethyl polysulphides leads to the complete demolition of these polysulphides, with formation of diethyl sulphide and mercaptan. Diethyl trisulphoxide is obtained by the action of nitric acid on diethyl trisulphide, and diethyl disulphone and trisulphone by the action of nitric acid on diethyl disulphide. The bearing of these results on the various formulæ proposed for the alkyl polysulphides is discussed.—**C. Jucci**: Distribution of the pigment in the strata of the cocoon of the reciprocal crosses (F_1) between two races of silkworms, the Chinese gold and the native yellow.

VIENNA.

Academy of Sciences, July 10.—**F. Friza** and **H. Przibram**: Johnston's sense organs in the tentacles (*Aristopeden*) of *Sphodromantis* and *Drosophila*. Concerning the nature of the regeneration after the amputation of the first or second joint of a limb.—**H. Przibram**: Influence of infundin and of adrenalin doses on the colour of the frogs *Rana esculenta*, *R. fusca*, and *H. arborea* (Causes of animal coloration, 12). Doses were kept below the fatal limit. The change of colour is not merely a death signal. There is a brightening of colour with weak doses of infundin. **H. Przibram**: Rôle of visual perception for colour changes in the frogs *R. esculenta*, *R. fusca*, and *H. arborea* (Causes of animal coloration, 13). To eliminate the effects of rough or smooth surfaces the frogs were placed in glass dishes, these being surrounded by coloured papers. The darker colour of the frog when on a darker background appears to be a visual effect.—**R. Zieske**: Influence of the extirpation of hypophysis or eyes on the colour changes of the frog *H. arborea*. A hormone of the hypophysis provokes an expansion of the melanophores and hence a darkening of the skin.—**J. Pollak** and **K. Deutscher**: The preparation of an *o*-amino-thio-phenol-sulphonic acid.—**E. Katscher**: Xylenol-sulpho-chloride and -sulphonylide. **A. Muller** and **P. Bleier**: Two syntheses of hepta-methylene-imine.—**A. Kailan** and **A. Irresberger**: The esterification of 3, 5 diamino- and of iodo-benzoic acid by ethylalcoholic hydrochloric acid.—**A. Kailan** and **A. Irresberger**: The influence of neutral salts on the velocity of reaction in alcoholic solutions. The varying results are explained as partly due to the combination of water with the salt. —**L. Waldmann**: Geology of the Rosalia hills. **L. Waldmann**: Geological studies in the mica schist zone of southern Bohemia.—**H. V. Graber**: Report on the geological and petrographical investigations in the Upper Austrian and south Bohemian primitive rocks. —**J. Regen**: The formation of stridulation sounds in some of the saltatory Orthoptera.—**A. Dadieu** and **K. W. F. Kohlrausch**: Studies on the Raman effect (10). The Raman spectrum of organic substances. Sixteen amino-bodies have now been studied. **A. Brukl** and **G. Ortner**: The sulphides of gallium. Three sulphides are reported, Ga_3S_2, GaS, and Ga_2S. —**F. Urbach**: The interpretation of Stokes's law. —Radium Institute Communications (No. 264), **F. Urbach** and **G. Schwarz**: Luminescence of the alkali halides. Measurements of thermo-luminescence on the hypothesis of 'loosened regions' (*Lockerstellen*). (No. 265), **F. G. Wick**: Experiments on radio-thermo-luminescence. Fluorites show a series of sharp bands possibly due to rare earths.—**B. Karlik**: Experiments on the luminescence of zinc sulphide and diamond under the influence of radioactive radiation. The α radiation from polonium destroyed the blue and green bands of zinc sulphide. The capacity for luminescence in the diamond was also destroyed by α-radiation.—**F. Hölzl**: The mobility of some ions containing iron. —**O. Dischendorfer**: On *o*-chlorbenzal-dinaphthol.—**O. Dischendorfer** and **H. Suvan**: Researches in the field of phyto-chemistry (6). Allobetulin.—**R. Reinicke**: The evaluation of the Raman spectrum of

CH_2Cl_2 by K. W. F. Kohlrausch. A discussion with the help of the tetrahedral carbon model of the exact angular positions of the chlorine atoms.—E. Bondy-Horowitz: Contributions to the anthropology of north-east New Guinea, published in book form.

Official Publications Received.

BRITISH.

Southern Rhodesia. Geological Survey Bulletin No. 16: The Geology of the Chromite and Asbestos Deposits of the Umvukwe Range, Lomagundi and Mazoe Districts. By Dr. F. E. Keep. Pp. 105+12 plates. (Salisbury, S.R.)

H.M. Treasury. Report of the Committee on the Staffs of Government Scientific Establishments. Pp. 45. (London: H.M. Stationery Office.) 9*d*. net.

Report of the Council of the Natural History Society of Northumberland, Durham and Newcastle-upon-Tyne, intended to be presented at the Annual Meeting of the Society, 4th November 1930. Pp. 40. (Newcastle-upon-Tyne.)

Proceedings of the Royal Irish Academy. Vol. 39, Section B, Nos. 20, 21, 22: The Ecology of the Mountains of Mourne with Special Reference to Slieve Donard, by J. I. Armstrong, J. Calvert and C. T. Ingold; Re-Colonisation after Peat-Cutting, by J. M. White; The Ecology of the Moss Lane Region, Lough Neagh, by Mary Duff. Pp. 440-496+plates 5-14. (Dublin: Hodges, Figgis and Co.; London: Williams and Norgate, Ltd.) 2s.

Publications of the Dominion Observatory, Ottawa. Vol. 10: Bibliography of Seismology. No. 5: January, February, March, 1930. By Ernest A. Hodgson. Pp. 67-86. 25 cents. No. 6: April, May, June, 1930. By Ernest A. Hodgson. Pp. 87-100. 25 cents. (Ottawa: F. A. Acland.)

Battersea Polytechnic, London, S.W.11. Report of the Principal for the Session 1929-30. Pp. 43. (London.)

FOREIGN.

Japanese Journal of Mathematics. Transactions and Abstracts, Vol. 7, No. 2, September. Pp. 101-198. (Tokyo: National Research Council of Japan.)

R. Osservatorio Astrofisico di Catania. Catalogo Astrofotografico Internazionale 1900.0. Zona di Catania fra le declinazioni $+46°$ e $+55°$. Vol. 8, Parti 7ª e 8ª: Declinaz. da $+53°$ a $+55°$, ascens. retta da 18h a 24h. (Fascicoli N. 63 e 64.) Pp. xi+151. (Catania.)

The University of Colorado Studies. Vol. 18, No. 1, August. Pp. 42. (Boulder, Colo.) 1 dollar.

United States Department of the Interior: Office of Education. Bulletin, 1930, No. 12: National Ministries of Education. By James F. Abel. Pp. ix+158. (Washington, D.C.: Government Printing Office.) 25 cents.

City Noise: the Report of the Commission appointed by Dr. Shirley W. Wynne, Commissioner of Health, to study Noise in New York City and to develop Means of abating it. Edited by Edward F. Brown, E. B. Dennis, Jr., Jean Henry, G. Edward Pendray. Pp. xii+308. (New York City: Noise Abatement Commission.)

Clouds. By Prof. Alexander McAdie. Pp. iii+22+52 plates. (Readville, Mass.: Blue Hill Observatory.)

Sailplaning. Pp. 43. (Clarendon, Va.: Soaring Flight Co.)

Memoirs of the College of Science, Kyoto Imperial University. Series B, Vol. 5, No. 3, July, Article 12: Contributiones ad Caricologiam Asiae Orientalis, Pars Prima. By Jisaburo Ohwi. Pp. 247-292. (Tokyo and Kyoto: Maruzen Co., Ltd.)

CATALOGUES.

New Design Vacuum Grating Spectrograph. Pp. 4. (London: Adam Hilger, Ltd.)

Watson's Microscope Record. No. 21, September. Pp. 32. (London: W. Watson and Sons, Ltd.)

Vegetable Parchment: its History, Manufacture and Uses. Pp. 12+2 plates+samples. (Northfleet, Kent: British Vegetable Parchment Mills, Ltd.)

Dr. Muller's Improved X-ray Goniometer Spectrograph. Pp. 24. (London: Adam Hilger, Ltd.)

Diary of Societies.

FRIDAY, NOVEMBER 7.

ROYAL SOCIETY OF MEDICINE (Otology Section), at 10.30 A.M.—A. R. Tweedie: Presidential Address.—Dr. D. McKenzie: The Pathogenesis of Cholesteatoma.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.—Sir Vijaya Raghava Acharya: The Work of the Imperial Council of Agricultural Research.

ROYAL ASTRONOMICAL SOCIETY, at 4.30.—Geophysical Discussion. In Chair, Sir Gerald Lenox-Conyngham.—Sir Gilbert Walker: Microseisms due to Meteorological Causes, followed by Dr. F. J. Whipple and A. W. Lee.—Dr. H. Jeffreys: (*a*) The Damping of Seismic Waves, and (*b*) The Revision of the Seismological Tables.

ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 5.—Dr. Chevalier Jackson and others: Discussion on Precancerous Conditions of the Larynx.

PHYSICAL SOCIETY (at Imperial College of Science and Technology), at 5.—Prof. S. Chapman: The Absorption and Dissociative or Ionising Effect of Monochromatic Radiation in an Atmosphere on a Rotating Earth.—Dr. W. N. Bond: Turbulent Flow through Tubes.—J. S. Badami: The Spectrum of Trebly Ionised Cerium (Ce IV).—J. S. Rogers: The Photographic Effects of Gamma-Rays.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Demonstration of Specimens of Surgical Interest recently added to the Museum of the Royal College of Surgeons.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Prof. J. W. Gregory: The Machinery of the Earth (Thomas Hawksley Lecture).

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle-upon-Tyne), at 6.—R. W. Allen: Feed-Water Systems for Steam Installations.

INSTITUTE OF TRANSPORT (Manchester, Liverpool, and District Section) (at Adelphi Hotel, Liverpool), at 6.30.—W. V. Wood: The Economic Position of Railways.

INSTITUTE OF TRANSPORT (Leeds and District Section) (at Town Hall, Leeds), at 7.—J. W. Mitchell: Some Aspects of Indian Transport.

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7.—E. Fawssett: Chairman's Inaugural Address.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group) (Informal Meeting), at 7.—Discussion on Prints contributed to the P.G. Portfolios.

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (jointly with Manchester Literary and Philosophical Society and Manchester Sections of British Association of Chemists, Institute of Chemistry, Institution of Electrical Engineers, Institute of Fuel, Institution of the Rubber Industry, and Oil and Colour Chemists' Association) (at the College of Technology, Manchester), at 7.—Sir William B. Hardy: Problems of the Boundary State (including Friction and Lubrication) (Lecture).

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (jointly with Institute of Chemistry, South Wales Section) (at University College, Swansea), at 7.30.—A. Stuart: The Study of Crystals with Special Reference to Chemistry.

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7.30.—H. Marryat: Luminous Electric Tubes (Neon, Helium).

ROYAL SOCIETY OF MEDICINE (Anæsthetics Section), at 8.30.—Dr. H. W. Featherstone: A Visit to some of the Hospitals in Canada and the Mayo Clinic (Presidential Address).

SATURDAY, NOVEMBER 8.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—A. Hamilton Smith: Some Recent Archæological Work in Italy (1).

BRITISH PSYCHOLOGICAL SOCIETY (at Royal Anthropological Institute) (Extraordinary General Meeting), at 3.30.

MONDAY, NOVEMBER 10.

ROYAL SOCIETY OF MEDICINE (United Services Section), at 5.—Group Capt. Martin Flack: Air-sickness and Sea-sickness.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—C. P. G. Wakeley: Demonstration of Specimens illustrating the Pathological Conditions of the Scalp and Cranium.

INSTITUTION OF AUTOMOBILE ENGINEERS (jointly with Institute of Transport and Commercial Users' Association) (at Institution of Electrical Engineers), at 7.—G. J. Shave: Passenger-carrying Vehicles.—C. le M. Gosselin: Goods-carrying Vehicles.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—A. F. Stevenson and others: Discussion on V.I.R. Cables; their Failures, their Future, and their Rivals.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Eastern Centre) (at Armstrong College, Newcastle-upon-Tyne), at 7.—D. B. Hoseason: The Cooling of Electrical Machines.

INSTITUTE OF METALS (Scottish Local Section) (at 39 Elmbank Crescent, Glasgow), at 7.30.—N. C. Marples: The Applications of High-Nickel, Nickel-Copper Alloys and Pure Nickel in Industry.

SOCIETY OF MOTION PICTURE ENGINEERS (London Section) (at Royal Photographic Society), at 7.45.—C. W. Glover: Sound Proofing a Studio.

SURVEYORS' INSTITUTION, at 8.—E. H. Leeder: Presidential Address.

BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College), at 8.30.—Symposium on The Nature of Stammering to be opened by Dr. Millais Culpin and Dr. E. J. Boome.

MEDICAL SOCIETY OF LONDON.—Prof. Chevalier Jackson: The Diagnosis and Treatment of Malignant Disease of the Chest.

TUESDAY, NOVEMBER 11.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Dr. C. D. Ellis: New Aspects of Radioactivity (2).

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.—Prof. A. W. Nash, H. M. Stanley, and Dr. A. R. Bowen: Synthetic Lubricating Oils.

INSTITUTE OF MARINE ENGINEERS, at 6.—Eng. Lt.-Comdr. S. F. Dorey: Tubes for High Pressure Water-Tube Boilers.

INSTITUTE OF METALS (Swansea Local Section) (at Y.M.C.A., Swansea), at 6.15.—Dr. H. W. Brownsdon: Alloys—Some Reasons for their Composition.

INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole, Leeds), at 7.

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (Associate Members' and Graduates' Section) (Manchester and District Branch) (at Milton Hall, Manchester), at 7.—A. Hindley: Some Unusual Jobs.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—L. W. Oliver: Progress in Colour Photography.

Hotel, Coventry), at 7.30.—G. J. Shave: Pass

—C. le M. Gosselin: Goods-carrying Vehicles.

SOCIETY OF GLASS TECHNOLOGY (jointly with Ceramic Society) (at North Stafford Hotel, Stoke-on-Trent), at 8.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Western Centre) (at College of Technology, Manchester) (jointly with North-Western Centre of Institution of Mechanical Engineers).—D. B. Hoseason: The Cooling of Electrical Machines.

WEDNESDAY, NOVEMBER 12.

SOCIETY OF GLASS TECHNOLOGY (jointly with Ceramic Society) (at North Staffordshire Technical College, Stoke-on-Trent), at 2.30.—J. T. Randall, H. P. Rooksby, and B. S. Cooper: The Structure of Glasses: The Evidence of X-Ray Diffraction.—E. J. C. Bowmaker: A Method for Determining the Plasticity of Clays and Clay Mixtures suitable for Glass House Refractories.—W. J. Rees: Specifications for Tank Blocks. —W. Emery: Notes on the Casting of Refractories.

ROYAL ANTHROPOLOGICAL INSTITUTE (in Portland Hall, Great Portland Street, W.1), at 5.30.—A. M. Hocart: Spirit Worshippers of the South Seas.

ROYAL SOCIETY OF MEDICINE (Surgery Section Sub-Section of Proctology), at 5.30.—L. E. C. Norbury: Multiple Primary Malignant Growths, with Special Reference to the Colon and Rectum (Presidential Address).

INSTITUTION OF ELECTRICAL ENGINEERS (Hampshire Sub-Centre) (at Municipal College, Portsmouth), at 7.30.—R. E. Horley: Oil-filled Cables.

ROYAL SOCIETY OF ARTS, at 8.—Prof. A. E. Richardson: The Royal Society of Arts Competition of Industrial Designs.

LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemistry Section) (at Leicester Museum), at 8.—F. Dransfield: Fuels (Presidential Address).

ELECTROPLATERS' AND DEPOSITORS' TECHNICAL SOCIETY (at Northampton Polytechnic Institute) (Annual Meeting), at 8.15.—Dr. R. S. Hutton: Presidential Address.

TELEVISION SOCIETY.

THURSDAY, NOVEMBER 13.

ROYAL SOCIETY, at 4.30.—G. Endres, B. H. C. Matthews, H. Taylor, and A. Dale: Observations on certain Physiological Processes of the Marmot, I.-V.—Dr. J. Gray: The Mechanism of Ciliary Movement.—W. S. Duke-Elder and P. M. Duke-Elder: The Contraction of the Extrinsic Muscles of the Eye by Choline and Nicotine.—*Papers to be read in title only:*—Dr. C. D. Darlington: A Cytological Demonstration of 'Genetic' Crossing-Over.—W. Moppett: The Differential Action of X-Rays on Tissue Growth and Vitality, II., III., IV.—Prof. J. Mellanby: Prothrombase—Its Preparation and Properties.—Dr. D. Keilin and R. Hill: The Porphyrin of Component *c* of Cytochrome and its Relationship to other Porphyrins.—A. Geiger: The Isolation by Cataphoresis of Two Different Oxy-hæmoglobins from the Blood of some Animals.—R. Deanesly: The Development and Vascularisation of the Corpus Luteum in the Mouse and Rabbit.

LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5. A. Bloch and G. Polya: On the Roots of Certain Algebraic Equations. —R. D. Carmichael: Expansions of Arithmetical Functions in Infinite Series.—W. L. Edge: On the Quartic Developable.—R. M. Gabriel: The Rearrangement of Positive Fourier Coefficients.—J. Hodgkinson: Note on one of Ramanujan's Theorems.—L. S. Bosanquet and E. H. Linfoot: On the Zero Order Summability of Fourier Series.—Prof. L. J. Mordell: A New Waring's Problem with Squares of Linear Forms.—A. Myller et O. Mayer: Géometrie differentielle centroaffine. Courbes Planes.—L. Roth: On Plane Forms in Four Dimensions.—Prof. G. N. Watson: Theorems Stated by Ramanujan (XIV.). A Singular Modulus.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. L. S. T. Burrell: Indications for Treatment in Pulmonary Tuberculosis (Mitchell Banks Lecture).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—J. H. Fisher: Ocular Muscles, Movements, and Judgments (Bradshaw Lecture).

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Prof. J. B. S. Haldane: The Physiology of Water (2).

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—A. E. Norris: The Methods of a Modern Reformatory.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6.30.—H. L. Stevens: Testing the Control of Aeroplanes.

INSTITUTE OF MARINE ENGINEERS (Junior Section), at 7.—E. R. Hall: Waste Heat Recovery.

INSTITUTE OF METALS (Birmingham Local Section) (at Chamber of Commerce, Birmingham), at 7.—Dr. W. H. Hatfield and others: Discussion on Metals and Alloys of the Future.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Colour Group), at 7.—A. Coleman: Demonstration of the Finlay Colour Process.

SOCIETY OF DYERS AND COLOURISTS (Midland Section) (at University College, Nottingham), at 7.30.—R. Burgess: Factors affecting the Development of Mildew on Wool.

OPTICAL SOCIETY (at Imperial College of Science), at 7.30.—Demonstrations of Photo-electric Cell Applications, illustrating some Important Properties which are made use of in Optical Work, Research Staff of the General Electric Co. Ltd.: The Use of the Spectrograph in Metallurgical Analysis, D. M. Smith: A New Spectrophotometer, H. Buckley and F. J. C. Brookes.

INSTITUTION OF ELECTRICAL ENGINEERS (Dundee Sub-Centre) (at University College, Dundee), at 7.30.—D. B. McKenzie: Automatic Railway Control.

INSTITUTION OF WELDING ENGINEERS (at Institution of Mechanical Engineers), at 7.45.—A. E. Shorter: Metal Surface Hardening.

ROYAL SOCIETY OF MEDICINE (Neurology and Ophthalmology Sections), at 8.30.—Dr. A. Lindau, T. Collins, Sir Percy Sargent, and others: Discussion on Vascular Tumours of the Brain and Spinal Cord.

FRIDAY, NOVEMBER 14.

ROYAL ASTRONOMICAL SOCIETY, at 5.—L. H. Thomas: The Slow Contraction or Expansion of a Fluid Sphere.—M. Bronstein: Note on the Temperature Distribution in the Deep Layers of Stellar Atmospheres. —V. C. A. Ferraro: (*a*) Note on the Possible Emission of Electric Currents from the Sun; (*b*) On Recombination in Ionised Streams of Corpuscles from the Sun.—Dr. H. Jeffreys: (*a*) The Resonance Theory of the Origin of the Moon (second paper); (*b*) Convection in Stars.—W. H. McCrea and G. C. McVittie: On the Contraction of the Universe. —R. H. Fowler: The Solutions of Emden's and Similar Differential Equations.—R. M. Peek: Photometric Observations of Nova Persei 1901.—S. Plakidis: Observations of Comet Forbes (1930 *c*) made with the Doridis Reflector of the National Observatory of Athens.—K. Nakamura: On the Observation of Faint Meteors, as experienced in the case of those from the Orbit of Comet Schwassmann-Wachmann, 1930 *d*.—A. Pannekoek: The Theoretical Contours of Absorption Lines. —Prof. E. A. Milne: The Analysis of Stellar Structure.

BIOCHEMICAL SOCIETY (at St. Thomas's Hospital Medical School), at 5.—R. D. Lawrence and R. A. McCance: The Effect of Phloridzin, Thyroid and Adrenaline on the Glycogen Distribution of the Rat.—E. C. Barton-Wright and J. G. Boswell: An Electric Furnace for the Micro-Combustion Method of ter Meulen.—B. C. P. Jansen, H. W. Kinnersley, R. A. Peters, and V. Reader: Curative Activity of Rice Antiberiberi Vitamin.—W. J. N. Burch: Esters of Phosphoric Acid.—R. K. Callow: The Purification of Yeast Ergosterol and the Separation from it of *a*-Dihydroergosterol.—F. Challenger, L. Klein, and T. K. Walker: A Note on the Mycological Production of Kojic Acid.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: An Account of Col. McCarrison's Experiments in the Production of Urinary Calculi, with an Exhibition of his Specimens.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle-upon-Tyne), at 6.—E. F. Spanner: Disembarkation of Passengers in Emergency at Sea.

INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section), at 6.15.—T. I. Illingworth: The Economic Application of Electricity to Space Heating.

ILLUMINATING ENGINEERING SOCIETY (at Royal Society of Arts), at 6.30. —J. A. Macintyre: The Lighting of Offices and Public Buildings.

SOCIETY OF CHEMICAL INDUSTRY (Newcastle Section) (jointly with Chemical Engineering Group) (at Armstrong College, Newcastle-upon-Tyne), at 6.30.—W. S. Coates: Caustic Embrittlement.

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (jointly with Institute of Chemistry, South Wales Section) (at Technical College, Cardiff), at 7.30.—Prof. S. Knox: The Chemist and the Coal Industry.

INSTITUTE OF METALS (Sheffield Local Section) (in Applied Science Department, Sheffield University), at 7.30.—Dr. H. Hyman: Unsoundness in Metals.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30. Annual General Meeting.

SATURDAY, NOVEMBER 15.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—A. Hamilton Smith: Some Recent Archæological Work in Italy (2).

PUBLIC LECTURES.

SATURDAY, NOVEMBER 8.

MATHEMATICAL ASSOCIATION (at Bedford College for Women), at 3.—A. H. Russell: Some Methods of Lightning Calculation.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—M. A. Phillips: Animal Childhood.

MONDAY, NOVEMBER 10.

UNIVERSITY COLLEGE, LONDON, at 5.—Dr. L. E. Bayliss: The Respiratory Functions of the Blood. (Succeeding Lectures on Nov. 17, 24, and Dec. 1.)

UNIVERSITY OF LEEDS, at 5.15.—Prof. J. W. Gregory: The Structure of Eastern Asia.

NATIONAL INSTITUTE OF INDUSTRIAL PSYCHOLOGY (jointly with London Safety First Council—Industrial Section) (at Institution of Mechanical Engineers), at 6.—Dr. G. H. Miles: The Psychology of Industrial Accidents.

TUESDAY, NOVEMBER 11.

KING'S COLLEGE, LONDON, at 11 A.M.—S. P. Turin: Russian Farming and Agriculture.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5.—Sir Leonard Hill: Atmospheric Pollution.

GRESHAM COLLEGE (Basinghall Street), at 6.—W. H. Wagstaff: Geometry. (Succeeding Lectures on Nov. 12, 13, and 14.)

MEMORIAL HALL (Farringdon Street).—Sir George Newman: Modern Collective Humanism at Work.

WEDNESDAY, NOVEMBER 12.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Dr. R. S. Williams: The Importance of a Complete Study of the Nutritional Value of Milk.

UNIVERSITY COLLEGE, LONDON, at 5.30.—L. A. Burgess: Public Libraries in Wales.

BELFAST MUSEUM AND ART GALLERY, at 8.—Rev. W. F. A. Ellison: Suns and Stars.

THURSDAY, NOVEMBER 13.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Dr. Marie C. Stopes: Present Day Technique and Clinical Results in Contraception.

BRITISH SCIENCE GUILD (in Goldsmiths' Hall, E.C.), at 4.30.—Sir William Pope: Science and Modern Industry (Norman Lockyer Lecture).

KING'S COLLEGE, LONDON, at 5.—Dr. W. Robson: The Metabolism of Proteins. (Succeeding Lectures on Nov. 20, 27, and Dec. 4.)

MEMORIAL HALL (Farringdon Street).—Sir George Newman: Gains and Losses in National Health.

FRIDAY, NOVEMBER 14.

BOROUGH POLYTECHNIC INSTITUTE, at 3.30.—Prof. J. T. MacGregor-Morris: Iron, Nickel, and Highly Permeable Alloys (Armourers and Brasiers' Company Lectures). (Succeeding Lectures on Nov. 21 and 28.)

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.15.—J. H. Coste: The Object and Methods of Sewage Treatment, particularly in relation to Inland Towns and Isolated Institutions (Chadwick Lecture).

SATURDAY, NOVEMBER 15.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—H. St. George Gray: The Lake Villages of Somerset.

SATURDAY, NOVEMBER 15, 1930.

Organic Chemical Research in relation to Industry.

AT the Bristol meeting of the British Association a discussion took place in Section B (Chemistry) on the position of the dyestuffs industry in Great Britain and the effect which the passing of the Dyestuffs Act, ten years ago, has had on the development of the industry and on activities connected therewith. The matter is of importance, because, unless some step is taken to renew the Act, either in its present or in a modified form, it will automatically lapse in December of this year.

Three questions arise in connexion with the working of the Act, and it is upon the answers to these questions that the issue depends. They are :

(1) What was the purpose of the Act ?

(2) Has it achieved that purpose ?

(3) If the answer to (2) is in the affirmative or qualified affirmative, will the lapse of the Act tend to re-establish the conditions which it was enacted to alter ?

In connexion with the first question, it is perhaps well to remember that the Act is an unusual measure, since it prohibits the import of all dyestuffs and intermediate products related thereto unless under licence. Licences are granted by a committee composed of dye-makers and dye-users, with a certain number of neutral members, and are issued in cases where the substances required are not manufactured in Great Britain.

The object of the Act is stated in an announcement made by the Government in 1920, which read as follows : "It is the settled opinion of the Government that for national security it is essential that synthetic colour-making factories should be in existence and be maintained in operation with their staffs of chemists and other experts in this country, and that the equipment should be equal in extent to that of any other possibly hostile nation."

This statement dealt with the subject from the point of view of national security in time of war—a matter of the highest importance, but one that has been stressed so often that no further comment is necessary here. The existence in Great Britain of highly trained chemists in control of plant and equipment of a type readily adaptable to the purpose of the manufacture of munitions of war is, unfortunately, essential until conditions are reached which will render the most elementary precautions unnecessary. Nevertheless, it is clear that the object of the Act was the establishment of a strong industry in connexion with the manufacture of dyestuffs and the intermediate products from which

they are derived, which would serve as a means for development and progress in times of peace but which would also be available in time of war; for it must be remembered, in the latter connexion, that it is the simplest of operations to utilise, at a moment's notice, the plant and personnel employed in dye and intermediate manufacture for the purpose of producing munitions of war. Moreover, it should be realised that, although not expressly stated, the Act covered and has influenced a far wider field than that it was designed to foster, because many substances dealt with in the fine chemical industry, and in industries dealing with medicinal substances and organic compounds of chemo-therapeutic interest, are either directly or indirectly related to the dyestuffs intermediates and are, therefore, covered by the Act.

The answer to the second question—Has the Act achieved its purpose ?—will be found by reference to the record of the meeting of Section B and to an excellent pamphlet just issued by the Association of British Chemical Manufacturers. The latter document deals with the views of the dyestuffs manufacturers on the progress which has been made under the Act of 1920, and although essentially an 'ex parte' statement, is nevertheless so concisely and clearly expressed that opponents to the extension of the Act, if such there be, will have some difficulty in combating the very cogent facts contained therein. The industrial and other difficulties which have militated against the development of the industry are enumerated and the conclusion is reached that, in spite of these, the Act has largely succeeded in achieving its main object, and that, as a consequence, we now have a well-organised, technically efficient, and virile industry. The 1929 production was more than six times that of 1913 by weight, and the home production now provides ninety per cent of the home consumption by weight and seventy-four per cent by value. The conclusion reached is that "while a sound foundation has been laid, and a strong structure is steadily being erected on efficient lines, there is still considerable headway to make before the industry can meet the full requirements of the colour-users, secure its proper share of the export trade, and withstand unaided the intensive foreign competition and price cutting which would result if this Act were allowed to lapse. The removal of the present protection would jeopardise the consummation of the work which it was the object of the Act to achieve." The dye-makers put forward the suggestion that, in order to ensure that no hardship should be placed on the colour-users, the Act should be extended i[illegible] form which will provide that prohibition of imports will only apply where a British maker is prepared to supply an equivalent product at an equal price.

In the summary of conclusion reached by the dye-makers it is stated that "the industry employs a larger proportion of technically-trained men than probably any other manufacturing industry in this country, and its existence is essential for the adequate maintenance of instruction and research in organic chemistry which are vital to our national prosperity and security". In other words, our research schools in organic chemistry are dependent on the industry for the employment of the trained men they produce, and, on the other hand, the industry is dependent on the schools of research for providing the skilled chemists without whom its work would be impossible. Prior to the War, manufacturers in Great Britain did not realise the need for highly trained men for service in the industry. Usually, all that was considered necessary was that a man should have obtained a sound general training in chemistry and allied subjects. It is certain that the pre-War predominance of Germany in scientific manufactures, and the fact that, in this connexion, we were rapidly becoming a nation of merchants, was due to the difference between the methods of training in the two countries. In Germany every chemist received a training in the methods of research, whereas in Great Britain probably ninety per cent of those seeking employment after graduation obtained no such training but entered the industry directly they had finished their course. Of the ten per cent remaining, the greater proportion went abroad to receive further instruction. Nowadays all that is altered.

Manufacturers have come to realise that, whether it is intended to place a man in the works as a process chemist, or whether it is intended that he should, in the first instance, enter the works' research laboratory, it is essential that he should have received at least one if not two years' training in research methods after graduation. It is fashionable in some quarters to disparage the Ph.D. degree, and to doubt the wisdom of the universities which have introduced it. No one who has any knowledge of the working of a large organic research school would do this. The degree is usually conferred after two years' training in research and indicates that the holder has undergone this training. It is a definite hall-mark which manufacturers are beginning to recognise, because they understand that the chemist possessing it has been trained to [illegible] know that no system of education can [illegible] dent with the technical minutiæ of

their manufactures—these can only be provided by them on the spot; but they know full well that a man with a trained mind will pick up those details very much more rapidly and effectively than one without such an advantage.

When the whole field of organic chemical research is envisaged, one realises the vast importance of the subject and the need to prevent any occurrence which may in any way hamper or hinder its development There are strong schools of research in most of our universities and university colleges, and from these emanates a steady stream of thoroughly trained men which is quickly absorbed into the industry There is no lack of employment. Indeed, during the past few years the demand has been in excess of the supply and heads of organic research laboratories have often been unable to provide the men asked for. Moreover, the demand is increasing, and this must inevitably be so, because the number of industries based on organic chemistry is increasing and is bound to increase Closer touch will also be effected between chemical industry and the research laboratories and further schemes will be devised for linking up the two, whereby the great potentiality for investigation and discovery resident in the universities will become available industrially.

It has been suggested that a certain measure of danger underlies the possession by a nation of strong and wealthy industries based on science, in that the best men turned out by the research schools may be attracted, by the offer of larger salaries, to abandon an academic career. If this were so, it would be fatal to the future development of both industry and academic science. If all the best men were attracted to industry, the second-rate men who remained would be unable effectively to control the research schools, which would then no longer be able to turn out first-class men. It is, of course, hopeless to suggest that matters could be adjusted by the universities paying salaries in any way commensurate with those obtainable in industry, but adjustment is certain to be reached by temperament: for in the future, as in the past, there will always be a number of first-class men to whom the 'loaves and fishes' of industry will offer no attraction, and who will be content to carry on research and investigation without any ulterior object. Moreover, there are many men to whom the love of teaching is a thing apart, and it is to these one must look for the adjustment of conditions which, at the present time, do undoubtedly present certain alarming features.

JOCELYN THORPE.

Taking Stock of Rubber.

(1) *Latex: its Occurrence, Collection, Properties and Technical Applications.* By Dr. Ernst A. Hauser. With Patent Review compiled by Dr. Carl Boehm von Boernegg. Translated by Dr. W. J. Kelly. Pp. 201. (New York: The Chemical Catalog Co., Inc., 1930.) 4 dollars.

(2) *Handbuch der Kautschukwissenschaft.* Herausgegeben von Prof. K. Memmler. Pp. xxiv + 766 + 10 Tafeln. (Leipzig: S. Hirzel, 1930.) 57·50 gold marks.

SCIENTIFIC investigation of rubber and rubber technology, apart from scattered researches, is a work of the present century. Growth of knowledge has been very rapid in the last decade, parallel with the enormous growth of the rubber planting industry in the East and of the tire industry in America and Europe. The two books under review give a timely and encyclopædic summary of current ideas in the field.

(1) Until a few years ago, latex, outside the producing countries, was only a colloid curiosity, but recent developments in its direct application, for example in the impregnation of textiles and in electro-deposition and dipping processes, have made it one of the most interesting materials in the rubber industry. Dr. Hauser was well fitted to write a monograph on the subject. He has made important contributions to our knowledge of latex, has investigated latex fresh from the tree in the East, and has studied one of the most urgent technical problems (that of latex concentration) intensively and on the works scale. In the result his book is admirably balanced and full of implications for further work. It may be said here, also, that the translation is done in lucid, enjoyable prose.

A historical introduction recalls the earliest patents for the use of latex, taken out in Great Britain by Samuel Peal and Thomas Hancock many years before the time was ripe for their inventions. The story is brought up to the foundation of the plantations from which the modern rubber industry dates. There follow chapters on the most important latex-bearing trees, on the collection of latex, the physical and chemical properties, non-rubber constituents of latex, less important latices, coagulation, evaporation, preservation and shipping, concentration, vulcanisation, and industrial applications. Chapter headings scarcely reveal the wealth of material dealt with in the book. Many difficult problems are critically examined and the text is frequently amplified by exhaustive bibliographies.

(2) Too many books devoted to general survey offer nothing but a superficial patchwork. Memmler's "Handbook" is very different from that; it is a comprehensive digest packed with detail, and offers an invaluable work of reference to the state of knowledge of rubber science at the present day.

There are seven main sections. The first, by Zimmermann, is devoted to the botany, cultivation, and preparation of rubber. There are chapters on every aspect of this field work, and such recent developments as electrophoretic and Emka rubber are discussed alongside *Hevea*, Manihot, and Jelutong. The chemistry of rubber is treated in the second section by Pummerer and Koch, and in this field we find the most important advances over the older text-books. Some chapters, such as those on halogen and oxygen derivatives of caoutchouc, contain little more than previous writers could say, but the chapters on the purification, crystallisation, and fractionation of rubber, on internal molecular rearrangement (cyclisation), on hydrogenation, and on the molecular weight and chemical constitution, show the remarkable progress recently made. A long chapter on synthetic rubber will be read with special interest on account of its author's association with the I. G. Farbenindustrie A.-G. The special question of vulcanisation is given a separate section by Kindscher and contains a good account of the part played by accelerators, while some less practical but theoretically interesting work on various types of vulcanisation, such as the Peachey process and the use of selenium and nitro-bodies, is adequately treated.

The fourth section, also by Kindscher, is on the chemical analysis of rubber. This is the one department of rubber science which has made little progress in recent years. The great interest taken in the mechanical testing of rubber, which began a couple of decades ago, has caused a definite neglect of chemical analysis. Such problems, for example, as the detection and determination of organic accelerators and preservative agents in rubber are barely touched upon; what little is said about them only emphasises the difficulties without throwing any helpful light.

The fifth section, by Hock, covers the fascinating subject of rubber physics. The mechanical structure of rubber stands out as the fundamental problem of rubber science in view of the unique mechanical behaviour of the material. In this book the structural conceptions are based on the thermo-elastic properties, and the important contributions of X-ray analysis to the subject are fully treated. Other chapters are devoted to the thermal, optical, and electrical properties of rubber, to its swelling and solution in fluids, and to rubber as a dispersing medium for filler particles. The sixth section, by Memmler and Schob, on mechanical testing, substantially follows the earlier work of Hinrichsen and Memmler, but contains valuable new sections on the plasticity of crude rubber and on ageing tests. The final section, by Pohle, constitutes the first general discussion of rubber microscopy yet written. It is illustrated with numerous beautiful reproductions in black and white and in colour of photomicrographs. The use and effect of stains in connexion with the dispersion of fillers is a revelation of delicate work.

Both these books conclude with full indexes of names and subjects, and are well printed.

T. R. D.

The Mosquitoes of North America.

A Handbook of the Mosquitoes of North America: their Structure, how they Live, how they carry Disease, how they may be Studied, how they may be Controlled, how they may be Identified. By Prof. Robert Matheson. Pp. xvii + 268 + 25 plates. (London: Baillière, Tindall and Cox, 1929.) 25s. net.

MALARIA, once very prevalent in the northern United States, has almost disappeared there, and is also less prevalent in the southern States, although here its diminution has been less marked and has proceeded at a slower rate. It has been suggested that the possible factors contributing to the decline of the disease have all been closely related to the agricultural development of the country, and, therewith, the reduction of habitats favourable to the breeding of the anopheline vectors. The danger of a serious increase of malaria in the northern States is not considered great, but under the less better developed conditions in the south, the likelihood of a recrudescence of the disease is much greater. In America, as elsewhere, mosquito campaigns in the past have been organised only when outbreaks of mosquito-borne diseases occurred. After the outbreak had diminished or disappeared, the passivity of responsible authorities frequently nullified the results of previous good work, and control operations had to be renewed with the recurrence of fresh outbreaks.

The successful control of mosquitoes depends on a thorough knowledge of their habits, which vary with the species. It is, therefore, essential that an exhaustive survey of the mosquitoes of the par-

ticular area to be controlled should first be made, including those that are migrants from adjoining districts, and finally, a topographical map of the area should be prepared showing the breeding grounds of the different species. With this information available, a definite plan for the ultimate reduction and elimination of breeding may be undertaken. Any plan will depend largely on local conditions, the extent and character of the breeding grounds, and the species of mosquitoes concerned. Whilst, then, malaria and yellow fever have been the greatest single factors conducive to the undertaking of active measures of mosquito control, it must not be forgotten that the anopheline carriers of malaria are but a mere fraction of the world's mosquito fauna, the majority of species of which are not concerned in the transmission of any disease, but thrust themselves unduly on the attention of man by their excessive abundance in certain regions and their irritating bites. Under such conditions, man's capacity for work and enjoyment in the open air is seriously interfered with, and valuable lands are rendered almost uninhabitable and remain undeveloped. This is particularly true of summer seaside and lake resorts, or urban areas subject to mosquito invasion, and of manufacturing and industrial districts.

In the United States the mosquitoes of New Jersey enjoy a reputation for bloodthirstiness that is second to none. Their abundance is traceable to the ideal breeding grounds, which occupy thousands of square miles of tidal salt-marshes adjoining the Atlantic seaboard. Here there flourish such migratory species as *Tæniorhynchus perturbans*, *Aedes vexans*, *A. sollicitans*, *A. cantator*, and *A. tæniorhynchus*. The abatement of the nuisance depends for its success on the ditching and drainage of the marshes. A true index of the success of the New Jersey anti-mosquito campaign is the steady appreciation in the land-values of adjacent residential areas during the past decade. Dr. T. J. Headlee, State Entomologist, New Jersey, is the authority for the statement "that where salt-marsh mosquitoes have been largely eliminated during the last ten years, there has occurred an average annual increase in taxable land-values of seventy-five per cent more than where they are still present or very recently reduced".

Problems of mosquito eradication similar to those of New Jersey also exist in California. In the valleys of most of the larger rivers of North America there occur special problems of mosquito control due to the annually recurrent conditions of flooding produced either by the melting snows of spring or the early summer rains. The mosquito pestilence of the lower Fraser River valley is entirely due to such conditions, and in some years assumes such proportions as to interfere seriously with the outdoor activities of the agricultural communities scattered along the valley. Likewise dependent for their development on the pools formed as a result of the melting snows are the majority of the species of *Aedes* of the northern Canadian prairie and tundra lands of the North-West Territories. No summer traveller to the Arctic but has experienced the annoying persistence of the countless myriads of *Aedes*, which in point of actual numbers far transcend any mosquito plague of the tropics. These northern species are but single-brooded, hatching from eggs deposited at random in the vegetation the previous summer. Whilst the period of overwintering diapause or latency only terminates with the recurrence of the requisite conditions of spring moisture, it is frequently prolonged so that many eggs only hatch after two or more periods of submersion separated by longer or shorter intervals. A comparable prolongation of the egg-stage of *Aedes argenteus* has recently been explained by Roubaud[1] (1929), not so much as an adaptation enabling the species to survive periods of dryness or unfavourable winter conditions, as a period of reactivation, during which the inhibitory effects of inherited toxins are overcome.

In connexion with mosquito breeding, one of the most urgent problems awaiting solution is the ascertaining of the physical, chemical, and biological factors, which determine the presence of certain species of mosquito larvæ in some pools and their absence in others. Variations of the *p*H values do not alone seem to offer a satisfactory explanation. Recent investigations would indicate that specific substances present in the water or produced by the decomposition of vegetable matter may be responsible for the growth of specific micro-organisms suitable or unsuitable as food for the larvæ.

The book before us discusses in a conventional manner the facts of mosquito morphology and biology, the relation of mosquitoes to disease, and the methods now commonly employed in combating mosquitoes. The final two chapters of the book are devoted respectively to a systematic account of the North American species of Anophelini and Culicini; of the former 8 species are described, of the latter 73 species belonging to 9 genera. It will serve as an admirable introduction to the more comprehensive work of Howard, Knab,

and Dyar, "The Mosquitoes of North and Central America and the West Indies", and of Dyar's "The Mosquitoes of the Americas". One of the great drawbacks to the advancement of culicidology has been the irksome synonymy, for which systematists and other students of the group have been largely responsible. It is, therefore, refreshing to those weary of tracking species invested with a protean nomenclature to find that at last systematists are beginning to agree upon the identity of many of our nearctic and palæarctic forms, with a consequent welcome reduction of spurious species. Further investigation will doubtless show that many others are merely varieties and not valid species.

The book is well illustrated by 23 text-figures and 25 plates, 7 of which are photographs of the breeding habitats of common species, whilst the remainder are composed of clear diagrammatic representations of larval and adult structures important in identification. There is a useful general index.

Prof. Whitehead's Philosophy.

Process and Reality: an Essay in Cosmology. (Gifford Lectures delivered in the University of Edinburgh during the Session 1927–28.) By Prof. Alfred North Whitehead. Pp. xxiii + 509. (Cambridge: At the University Press, 1929.) 18*s*. net.

IT does not fall within our scope to attempt a detailed or technical examination of the volume of Gifford Lectures in which Prof. A. N. Whitehead has expounded at greater length than elsewhere his system of metaphysics. This has been done in many other notices, and we would be understood here only to give a general impression from rather a lay point of view, comparing it with other newly published syntheses of similar scope—for example, that of Profs. Alexander and Haldane, Pringle Pattison and Hobson, and Sir Arthur Eddington.

Gifford lectures always open up a prospect of such fresh attempts to bring together the conclusions of science and put them into some sort of living relation with religion. It is an increasingly difficult task, and one should be grateful to the valiant men who essay it and the foundation which encourages them. It is doubtful, however, whether much has yet been achieved in the direction which most of the lecturers have had in view, mainly for two reasons: either they restate their old religious and metaphysical preconceptions side by side with a summary of certain aspects of recent science—this was the method, among others, of two eminent Gifford lecturers, Eddington and Haldane—or they undertake quite a new construction of their own, with a new phraseology and new ideas very difficult to accommodate to accustomed usage; Prof. Whitehead is the greatest example of this type, Prof. Alexander inclining towards him, but with much more tenderness to our traditional language and ways of thought, and also—the most important point—a much more thorough and accurate psychological analysis.

In Prof. Whitehead's work, whether in this volume or in the better-known "Science and the Modern World", we are constantly enlightened by some inspired phrase or conducted to a new vista of unity between the thinkers of the past and the opening realms of thought in the future. In this sense Prof. Whitehead is himself one of the builders of unity, a potent force in the new renascence of "the universe which is thus a creative advance into novelty". But when we turn to the system itself which he has elaborated with so much patience and ingenuity, we are overwhelmed by a cloud of perplexities and doubt.

The first and most obvious cause of this embarrassment is the extraordinary obscurity and redundance of the language. Here is a comparatively simple sentence, selected rather for that reason out of a multitude of others which on every page have confounded the wits of the most practised readers: "The depositions of Plato, Aristotle, Thomas Aquinas, Descartes, Spinoza, Leibniz, Locke, Berkeley, Hume, Kant, Hegel, merely mean that ideas which these men introduced into the philosophic tradition must be construed with limitations, adaptations, and inversions either unknown to them or even explicitly repudiated by them." What does this sentence tell us except that "No philosopher's words can be taken as final"? This, however, is a simple case. The greatest difficulty arises when the author adds to this redundancy of ordinary expressions the whole apparatus of a new terminology which he has himself invented and he himself remains the only writer to employ. No doubt an author is justified in introducing words carefully framed to express ideas which he cannot find adequately expressed in accepted phraseology. But clearly he must, if he wishes to be read and understood, do this with the utmost care and moderation.

Now, Prof. Whitehead, thinking that he has a great new idea to expound which dominates all his thought, has not only transformed one familiar word to express this new thought, but has added to it a whole string of others which constantly recur in the midst of long and complicated sentences. The leading word transformed is, of course, 'organism', and with this come entity, superject, prehension, concrescence, and many more. Some are new coinage, others are old words used in a novel and not always strictly consistent sense.

This coinage of new words goes further than merely verbal explicitness—which, in fact, it does not secure. The deeper difficulty is that having set up the one great idea with its new denomination of 'organism' and 'organic', the author is apt to proceed and to move in a completely new world of thought, more and more detached from the world of familiar fact from which he sets out.

This starting-point for the new philosophy is given in an early passage as follows: the "doctrine of the philosophy of organism is that, however far the sphere of efficient causation be pushed in determination of components of a concrescence—its data, its emotions, its appreciations, its purposes, its phases of subjective aim—beyond the determination of these components there always remains the final reaction of the self-creative unity of the universe. This final reaction completes the self-creative act by putting the decisive stamp of creative emphasis upon the determinations of efficient cause." This final 'self-creative unity' is what the author means by 'God', who is elsewhere defined, more briefly in the same direction, as "the principle of concretion".

One understands in a vague sense what this aims at. It has close affinities with other large general ideas current at the moment, especially Gen. Smuts's 'holism'. It has a value, no doubt, in raising the mind above the complexities of particular events: above all, in connecting the idea of creation with that of increasing order and unity in the world. But when applied *ab extra*, as it were, overriding the known distinctions, for example, of the living and not-living, the conscious and the unconscious, it confuses and does not enlighten us. For one reader at least, full of admiration for the author and sympathy with his general aim, more light comes from the less ambitious but more faithful psychological analysis of the school of Bradley and Alexander.

F. S. MARVIN.

Our Bookshelf.

Air Ministry: Meteorological Office. The Weather Map: an Introduction to Modern Meteorology. (M.O. 225i.) Second edition, entirely rewritten. Published by the authority of the Meteorological Committee. Pp. iv + 83 + 24 plates. (London: H.M. Stationery Office, 1930.) 3*s*. net.

THE first issue of "The Weather Map" was published in 1915, primarily in response to military requirements, and was in considerable demand for the succeeding ten years, as is shown by the fact that six reprints were made during that period. Mr. J. S. Dines, while superintendent of the forecast branch of the Meteorological Office, rewrote the work and brought it up-to-date.

There are numerous improvements in the new volume, the most obvious of which are visible at a glance in its better finish throughout, and especially in the cover and in the reproduction of the weather maps. It may be noted, however, that in order to exhibit the weather at individual stations clearly, the area covered by the maps is about the same as for those published in such morning newspapers as reproduce the map for 6 P.M. of the previous day. This area is very small compared with that of the 'working chart' of the official forecasters—a fact which should be borne in mind when considering the process of preparation of the forecasts. There must be a great many people who would follow with interest the changes depicted in these maps, could they master the meaning of all the symbols and figures that appear on them, and their requirements are well met in the full and clear exposition given of the make-up of a modern synoptic weather map.

To those whose interest carries them further, and who require some insight into the kind of reasoning followed by the official forecaster in making his diagnosis of a particular situation, the same attention has been paid, and there is little doubt that present-day technical methods of prediction have been made comprehensible to anyone with an elementary knowledge of physics, and not wholly unintelligible to those without such knowledge. It is good to see also that the history of the subject has not been neglected, and that a careful account has been given of the new ideas that have come to us in recent years from Norway owing to the analytical methods worked out by J. Bjerknes with the aid of a closer network of stations than is normally employed in synoptic meteorology. The amount of information and the clearness of its exposition are remarkable for the size of the volume. The teaching profession should derive especial benefit from its appearance.

In a Persian Oil Field: a Study in Scientific and Industrial Development. By J. W. Williamson. Second edition, revised and enlarged. Pp. 192 + 25 plates. (London: Ernest Benn, Ltd., 1930.) 7*s*. 6*d*. net.

IT is quite evident from the call for a second edition of this book that public interest in the oil industry extends beyond markets. Written originally for the non-technical reader to convey "a judicious

appreciation" of the work of a British oil company, apparently sales and certainly reviews commended the volume to the technologist, a source of gratification to its author, who modestly reiterates in his second preface its real purpose: to serve the general reader.

Probably one of the chief reasons for the success of this essay is the fact that it is unique of its kind. At first glance one might wonder, and with every reason, what there was in the business of oilfield exploitation to appeal to anybody outside those directly concerned, outside the technical circle. But the story of a self-contained British community operating in alien country, contending not only with a difficult people, but also with Nature in her sternest mood, every individual and collective effort directed to one goal, the winning of petroleum and all that this to-day stands for, provides an author with a wealth of material, technical, human, psychological, social, out of which, if he be worthy of his pen, he cannot fail to make abundant literary capital.

The chief departure from the first edition is the inclusion of a chapter on "Oil and Ethics", which, designed to portray the achievement of the company concerned in correct perspective of international industry, throws into sharp relief the other part of the book. Otherwise the alterations are mainly those of righting mistakes, revising sections which clearly wanted attention in the original, and extending the information on those particular operations, for example, geophysical, which have been prominent in the interim. To criticisms made to the reviewer, that the title is an intended parody on a popular song, and that the book is an excellent form of publicity for a commercial undertaking, we reply that, even if either or both are justified, anything which brings home to the general reader what a wonderful substance is petroleum, what praiseworthy enterprise and high standard of human attainment are involved in its exploitation, deserves the fullest approval. H. B. M.

Rudi Schneider: a Scientific Examination of his Mediumship. By Harry Price. Pp. xv + 239 + 12 plates. (London: Methuen and Co., Ltd., 1930.) 10*s.* 6*d.* net.

THIS volume gives an account of two series of sittings held under the auspices of the National Laboratory of Psychical Research, of which the author is the honorary director. The medium in whose presence alleged psychic phenomena are said to have taken place was a young Austrian, by name Rudi Schneider, who with his brother Willi have for some years held the position of the principal European mediums for the so-called physical phenomena.

The present series of sittings is said to have been held primarily in order to interest as many scientific men as possible, although the list of sitters scarcely lends support to this statement.

The control of the medium and observers was mainly exercised by an electrical device whereby any movements which resulted in breaking the circle were registered by the extinction of certain lights, and thus both medium and sitters were immobilised and (it is claimed) prevented from indulging in any trickery. Under these conditions a number of manifestations are recorded, such as the movements of objects without contact and the appearance of hands seemingly endowed with life. Notes were taken by a lady secretary, who dictated them into a dictaphone as the events occurred, but the few independent accounts that Mr. Price prints show that these notes should be regarded with some caution.

Generally speaking, the book is an interesting addition to the studies of the Schneider phenomena, although the treatment of past history is scarcely ingenuous. From its perusal the uninformed reader would scarcely gather that a formidable mass of evidence exists to justify suspicion regarding phenomena identical, or nearly so, with those now said to occur with the electrical control.

A History of Medicine. By R. McNair Wilson. (Benn's Sixpenny Library, No. 148.) Pp. 80. (London: Ernest Benn, Ltd., 1930.) 6*d.*

IN a very small compass, the author gives an excellent survey of medical history. Beginning with the medicine of the Greeks, he emphasises the influence of Hippocratic humoral conceptions and the later Roman 'methodist' theory and the Galenic theory of the pneuma upon the development of medical science. An admirable plea for recognition of the value of earlier English medicine is made, with special reference to the works of Harvey and Sydenham. Jenner's discovery of the use of vaccines is also well described, and this is followed by a good analysis of the work of Pasteur. From 1880, great strides have been made in antiseptic surgery and the application of antitoxic sera, and the author gives his readers a glimpse into this revolutionary period in medical history.

The book terminates with a brief review of the development of preventive medicine which has resulted in the establishment of the Ministry of Health and the Medical Research Council, the study of mental sickness, and cancer research. The work is altogether a splendid effort, and may be read with interest, both by medicals and laymen.

Plant Biology: an Outline of the Principles underlying Plant Activity and Structure. By Dr. H. Godwin. Pp. x + 265. (Cambridge: At the University Press, 1930.) 8*s.* 6*d.* net.

ELEMENTARY text-books of botany usually bear a strong family resemblance, and it is therefore a pleasure to notice one bearing the hall-mark of individuality. This book treats the plant as an active unit, and at the same time emphasises the physico-chemical bases on which it works. Particularly useful are the schemes showing the types of metabolism and energy relations of the yeasts and bacteria. We may welcome also the illustration of the tissue elements as solid objects, and also the developmental treatment given to the morphology of flowering plants.

Crystal Structure of Parahydrogen.

WE have made two Debye-Scherrer films of parahydrogen cooled by helium boiling under normal pressure, yielding rather faint and granular lines. A much better intensity was obtained when the solid was irradiated at a temperature less than 2° K. The spacings which were deduced from these films cannot be explained by a simple space lattice of cubic symmetry.

A hexagonal close-packing of molecules, with $a = 3 \cdot 75$ A. and $c/a = 1 \cdot 63$, gives a satisfactory agreement between observed and calculated spacings. For the density we compute then 0·088.

A more detailed account of these experiments is being published in the *Proceedings* of the Royal Academy of Amsterdam.

A Sex-linked Character in Ducks.

ALTHOUGH sex-linked characters are known in fowls, pigeons, doves, and canaries, none has hitherto been recorded in ducks. From the industrial point of view, a sex-linked character affecting the down of the newly hatched duckling, enabling the sexes to be distinguished at this stage, would be of considerable importance; for the runner duck, though a magnificent layer, is comparatively valueless for table purposes. It is true that the sexes can be distinguished by a careful examination of the cloaca even at hatching, but this as a rule demands more skill on the part of the operator than the average duck farmer possesses.

Some experiments carried out this year have revealed the existence of a sex-linked character which will probably provide the industry with what it desires. Reciprocal crosses were made between the common mallard and the Indian runner, a race with rather blurred markings on a buffish ground. From the mating between runner duck and mallard drake, 19 birds were produced, all with a dark type of down resembling that found in the mallard. Of these, 10 were drakes and 9 were ducks. From the mating between mallard duck and runner drake, 47 young were produced, of which 27 were drakes and 20 were ducks. The down of the drakes was similar to the down of all the ducklings from the reciprocal cross, but the down of the ducks was much lighter, and nearer in ground colour to that of the runner. The colours of the two types of down cannot be matched exactly in Ridgway's "Colour Standards", but the lighter one is close to the "light brownish olive" on Plate XXX., while the darker is not far removed from the "dark olive" of Plate XL. All the downs, whether light or dark, were yellowish on the ventral surface, and showed yellow rump patches dorsally. Such pale markings are not characteristic of the runner, and are probably due to a dominant factor brought into the cross by the mallard.

On reaching maturity, the birds with the dark downs exhibited a type of plumage closely resembling that of the mallard, whether male or female; but the ducks from the mallard ♀ × runner ♂ developed a distinct and paler type of plumage, which was noticeable also for the marked reduction of the characteristic bright 'speculum' on the wing.

In its general features the case recalls that of the 'cinnamon' canary, and it is interesting that in this species also the inheritance is sex-linked. Finally, it may be added that Werner (*Anat. Rec.*, 1925) has shown that the female runner, like all other birds adequately investigated, possesses only one X-chromosome.

R. C. PUNNETT.

Science and Philosophy.

THE suggestion by Prof. F. G. Donnan (NATURE, June 7, 1930) that an international conference of scientists and philosophers, and perhaps others, might help toward clarifying the present confused state of men's thinking on most of the major problems of Nature and human life, has received considerable notice in America, at least.

A later communication to NATURE (June 21) by Mr. Wilfred Trotter directs attention to the extent to which the biological sciences have "lost prestige in the intellectual world" in the last thirty years, and "ceased to influence philosophic thought". No one who to-day views the field of human interest broadly and thoughtfully can fail to recognise the general truth of the point made by Mr. Trotter. If one desires an illustration of this truth in relation to philosophy, let him compare such writings as Prof. John Dewey's "The Influence of Darwin on Philosophy" (1909) and his "The Quest for Certainty", published just twenty years later. Or if one wants an illustration of the present standing of biology in the realm of ethics, he may reflect on the insignificant and hopeless creature man is from the "particular point of view which the biologist adopts" (Walter Lippmann, "A Preface to Morals", p. 150).

I venture to direct attention to a matter which, though far less than the whole problem of the relation between science and philosophy, yet has long appeared to me to have an important bearing on that problem. The point concerns the now widely adopted classification of the sciences into 'exact science' and 'natural science'. A brief historic reference illustrates what is in mind.

In the "History of Scientific Ideas" (2nd ed.; London, 1847) William Whewell wrote, quoting from his previously published "Philosophy of the Inductive Sciences": ". . . the mathematical and mathematico-physical sciences have, in a great degree, determined men's views of the general nature and form of scientific truth; while natural history has not yet had time or opportunity to exert its due influence upon the current habits of philosophizing".

That Whewell was greatly impressed by this idea is clear from his recurring to it under various heads and in others of his writings. Thus in his "Novum Organum Renovatum" (London, 1858) we read: "Natural history ought to form a part of intellectual education, in order to correct certain prejudices which arise from cultivating the intellect by means of mathematics alone; and in order to lead the student to see that the division of things into kinds, and the attribution and use of names, are processes susceptible of great precision".

These views were expressed by Whewell, it will be noticed, before the publication of "The Origin of Species" and Darwin's other works, which laid a solid foundation for the theory that man himself with all his attributes is a natural product and so holds a definitely ascertainable place in the world of living organisms. But Whewell's appraisal of natural

history referred only to its general educational and logical bearings. Natural history as dealing with that domain of Nature to which man himself belongs had received no serious consideration by him. Only since his time, and to the extent that man has accepted the theory of 'descent with modification' as applying to his own origin and nature, has it been possible for anybody to see that if ever man is to attain that measure of self-knowledge after which the wisest ones of all races have longed and striven, that knowledge must partake much more of the character of 'natural science' than of 'exact science', using these terms as they are now largely understood.

The following then is suggested as one opportune subject for treatment at such a conference as that proposed by Prof. Donnan: The ancient injunction, Know Thyself, may be placed on a scientific-philosophic basis by developing to its fullness the partial insight gained by William Whewell of a natural history mode of philosophising. W. E. RITTER.

Ancient Metallurgy in Rhodesia.

MY attention has been directed to an article on "Early Man in N. Rhodesia", by Prof. Raymond Dart, which appeared in the *Times* of Aug. 22 and was noticed in NATURE of Aug. 30. Echoes of the statements made in the article are finding their way into our local Press, and the unprotected public is being told that iron was being fabricated "3000 to 4000 years" ago by a people of Palæolithic culture dwelling in central Africa.

On the face of it, such an accomplishment is highly improbable, because the oldest man-made iron of known date is that of the discovery made by Sir Flinders Petrie at Gerar, in Palestine, in 1927. The date of this iron, as determined by associated scarabs and amulets, is 1350 B.C. It is probable that the smelting of iron was begun a little earlier, say, 1400 B.C., in the Hittite uplands, between the Taurus and the Caucasus, a region to which classical tradition points as the cradle of metallurgy. All iron earlier than 1400 B.C. is probably of meteoric origin; many older relics have been tested for their nickel content (which is the criterion) and have proved to be of celestial metal. It is unlikely that the smelting of iron was known long before 1350 B.C., because the knowledge of the art would have been of supreme importance, in trade and war, to any primitive people; it would have sufficed to give them instant dominance over their contemporaries.

We must meet Prof. Dart's conclusion, therefore, with justifiable scepticism. He says: "These facts reveal the extreme age (3000 to 4000 years) of the knowledge of smelting and the working of metals in Northern Rhodesia". This dictum is based upon the finding, by an Italian scientific expedition, of a foundry, slag, and ashes at a depth of six feet in a deposit containing implements characteristic of the Stone Age. The deposit lies within a limestone cave at Mumbwa, near the Kafue river, a tributary of the Zambezi. The find is said to prove that "the smelting is coeval with the later phases of the Palæolithic period in Northern Rhodesia", and shows that "the knowledge of metallurgy was introduced by a superior race into an Africa still in the throes of the Stone Age". This is true enough, but it does not prove an antiquity of 3000 or 4000 years, that is, so long ago as 2070 B.C. What it does prove, I submit, is that foreigners, versed in iron-making, established themselves for a time in the cave, possibly for self-defence, and during their sojourn they made iron weapons for use against the natives, who then were using the "quartz flakes and quartz implements of the Late Stone Age type"—in short, were the savages that Livingstone, Cameron, and Stanley found in that part of the world seventy years ago.

The invaders probably were slave-hunting Arabs, and the date of their incursion may be anything from A.D. 1200 to A.D. 1900, but no B.C. chronology is permissible. The Italian expedition has not finished its exploratory research; perhaps when all the information available is collected we shall be given a more convincing interpretation of the facts.

Apropos of early iron-making, I may mention that sundry writers have imputed the ancient Egyptians' knowledge of the art to a borrowing from their southern neighbours, the Ethiopians, this idea being lent some colour by the fact that the natives in central Africa, more particularly the Kenya and Congo regions, know how to make iron in a crude manner. Crudity of method, however, does not prove antiquity of origin. The denial to any such supposition is found in the description by Herodotus of the weapons used by the Ethiopian contingent in the army of Xerxes. Their armament consisted of "long bows, on which they placed short arrows made of cane, not tipped with iron, but with stone that was made sharp, and of the kind of which we engrave seals. Besides these they had javelins, tipped with antelope's horn that had been made sharp, like a lance. They had also knotted clubs." All of which indicates a complete ignorance of metallurgy. T. A. RICKARD.

The Nature of the Vacuome and the Golgi Apparatus in Oogenesis.

I HAVE read with great interest the recent communications of Miss M. O'Brien and Prof. Gatenby (NATURE, June 14, 1930) and of Prof Bhattacharya and Dr. Das (NATURE, Nov. 2, 1929) on the *Lumbricus* and the pigeon ovary respectively For the first time these authors have demonstrated that in the egg cells also the vacuolar system (vacuome) and the classical Golgi apparatus are independent cell-components. A similar conclusion has already been arrived at in plant cells by Bowen (*Z. Zellf.*, 1928) and by Patten, Scott, and Gatenby (*Quar. Jour. Roy. Mic. Soc.*, 1928), in animal male germ cells, by Hirschler, Monné, Voinov, and Gatenby (for references see Gatenby, *Proc. Roy. Soc*, 1929), and most recently in animal somatic cells also by Beams (*Anat. Rec.*, 1930), and by Gatenby and O'Brien.

Now both in the case of the earthworm and the pigeon ovary the use of neutral red has been found necessary to demonstrate the vacuolar system. Prof. Gatenby and his collaborator, therefore, have been naturally careful in stating that "it does not seem possible entirely to dismiss the idea that these globules might be segregation vacuoles and not pre-existing structures".

On the other hand, in the eggs of *Rana tigrina* (Nath, in press) and the teleostean fishes *Ophiocephalus punctatus* and *Rita rita* (Nath and M. D. Nangia, in press), not only the mitochondria and the Golgi elements but also the vacuoles can be seen *intra vitam* side by side separately *without the aid of neutral red or osmic acid*. This is due to the greater density and the larger size of the vacuoles of these three species. In *Ophiocephalus punctatus* the vacuoles begin condensing inside them protein material from a very early stage in oogenesis and actually form the albuminous yolk of the egg, as has been very rightly claimed for *Perca* and *Pygosteus* by Hibbard and Parat

(*Bull. d'Hist.*, 1928) and by Hibbard for *Discoglossus* (*Jour. Morph. Physiol.*, 1928).

In their chemistry the vacuoles of the eggs of *Rana*, *Ophiocephalus*, and *Rita* are diametrically different from the Golgi elements. Whereas the latter consistently go jet-black in either Da Fano or Mann-Kopsch or Kolatschev, and cannot be stained with neutral red, the former do not show the slightest amount of blackening however heavy the impregnations, and are stainable with that vital dye. The Golgi elements are certainly lipoidal (fat-like), whereas the vacuoles represent an aqueous material of a non-lipoidal and non-fatty nature.

I desire to pay tribute to the brilliant researches of Prof. Parat and his collaborators who have focused attention on a hitherto neglected cytoplasmic component, the vacuome, which in oogenesis may give rise to albuminous yolk as in *Perca*, *Pygosteus*, and *Ophiocephalus*. But the vacuome is not the Golgi apparatus as claimed by the Parat school. The classical Golgi apparatus may often be vesicular or vacuolar in form as in so many eggs (Nath, Gresson, etc., etc.) and even in other cells, for example, Protozoa (Hirschler, *Z. Zellf.*, 1927), but chemically and functionally it is a fundamentally different material from the vacuome. The Golgi vesicle is not a mere vacuole, but is surrounded by a thick lipoidal cortex which is characteristically argentophile and osmiophile.

Manner in which Flaps of various Materials fracture along their Bases.

WHILE studying the various methods in which osteoplastic flaps for exposing the brain and its membranous coverings may be formed from the human skull, my attention has been directed to the way in which fracture takes place along the bases of bone

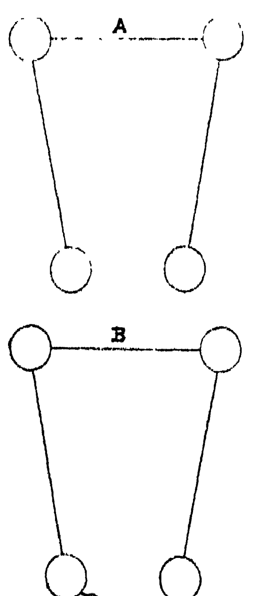

FIG. 1.

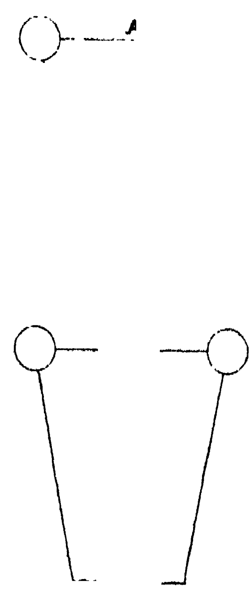

FIG. 2.

flaps. The type of fracture appears to depend upon the manner in which the limits of the proposed base line are cut.

If, by cutting three sides, a flap is fashioned so that the base lies between two trephine holes (Fig. 1, A), and the flap so formed is then bent outwards until fracture occurs along the base line, this line will be found to be jagged and irregular (Fig. 1, B). If, however, by cutting three sides, the flap is fashioned so that the base lies between saw cuts (Fig. 2, A), and the flap so formed is bent outwards until fracture occurs along the base line, this line will be found to be even and regular (Fig. 2, B). I have verified this on numerous occasions, and have also fashioned flaps from, and performed the same experiments with, other materials, such as three-ply wood, dried bone, and cardboard, and find that the results are constant in each case. The difference in the type of fracture of the base line no doubt depends upon the difference in concentration of stress at its limits.

In an article on osteoplastic craniotomy in the current number of the *British Journal of Surgery*, I have directed attention to the facts outlined here, but I believe that they may have a wider application than cranial surgery, and hence this letter.

Autosyndesis among *Crepis setosa* Chromosomes.

IN a paper [1] dealing with the connexion between cytology and taxonomy, Prof. Tischler makes a statement to the effect that the four haploid chromosomes of *Crepis setosa* conjugate to form two pairs at the time of meiosis in the species hybrid *Crepis biennis* (n 20) $\times$ *C. setosa* ($n=4$). This he credits to us in a paper [2] in which we described a constant fertile form, *C. artificialis*, derived from these two species. Prof. Tischler also expresses doubt as to the occurrence of such a phenomenon. He says (p. 48): "Nicht dur die 20 Chromosomen der ersten Art schlossen sich autosyndetisch zu Paaren zusammen, sondern auch die 4 der zweiten. Wir erhalten so 12 Gemini. Und es ist doch die Zerlegung der vier Chromosomen in zwei einander 'homologe' Paare mehr als unwahrscheinlich."

The purpose of this letter is to direct attention to the fact that Prof. Tischler has misread our description of the origin of *Crepis artificialis*. This new species arose from a fourth generation plant of the cross between the two species *C. setosa* ($n=4$) and *C. biennis* ($n=20$). In the F_1 the 20 *biennis* chromosomes conjugate to form ten pairs while the *setosa* chromosomes remain as univalents and are distributed at random to the gametes. Thus all the F_2 progeny receive 20 *biennis* chromosomes (10 pairs) and a random number from *setosa*. *C. artificialis* arose from the union of two gametes, each of which had received 10 *biennis* chromosomes and the same two *setosa* chromosomes, thus producing a diploid complex having 20 *biennis* chromosomes (10 pairs) and 4 *setosa* chromosomes (2 pairs). Only two of the four types of *setosa* chromosomes are present in the fertile form called *Crepis artificialis*. This fact was repeatedly pointed out in the paper to which Prof. Tischler refers.

The following quotations from our original paper should be sufficient to correct the statement quoted above. "The two *setosa* chromosomes in the *artificialis* complex are quite readily recognized by their morphological characters and each is present twice. These are the first and fourth types mentioned above" (p. 309). "*Crepis biennis*, a species with 20 pairs of chromosomes, has been crossed successfully with two other species of *Crepis*, namely, *C. parviflora* Desf. and *C. rubra* L. During gamete formation in these F_1 hybrids, Mrs. Lesley found that, as in the *biennis-setosa* F_1, the 20 *biennis* chromosomes conjugate to form 10 pairs, while the chromosomes from the other

species remained as univalents and were distributed at random. We have also observed this phenomenon in a more recently made hybrid of *biennis* and *setosa*" (p. 305).

The Mechanism of Formation of the Latent Photographic Image.

IN 1925, with S. E. Sheppard and R. P. Loveland, I proposed the concentration speck theory of the latent image.[1] According to this hypothesis the action, during exposure, of pre-existing silver sulphide-containing specks (discovered by S. E. Sheppard [2]) on the surface of the silver halide grains of photographic emulsions, is confined to increasing their size by accretion of photochemically reduced silver atoms to form a nucleus large enough to induce developability. A mechanism of the formation of the latent image was proposed by me [3] on the basis of the experimental results of G. B. Gudden and R. Pohl on photoconductance.[4] It was supposed that the speck contains silver and silver sulphide, which, adsorbed on the surface of the silver halide crystal, form the electrodes of an elementary voltaic cell of the type $Ag/AgBr/Ag_2S$ having silver halide as the electrolyte, the external circuit being completed by contact between the silver and the silver sulphide. The growth of the speck is due to the electrolytic deposition of silver from the electrolyte.

In a recent criticism F. C. Toy and G. B. Harrison [5] regard such a theory as difficult to accept in the light of their experimental results. They point to the fact that exposure to light for a fraction of a second will normally make a photographic emulsion developable. They think that it would require an enormous increase in the voltage of the cell or a corresponding increase in the electrolytic conduction of the electrolyte to produce in this way a developable centre. This is not necessary. It is evident that the larger the speck is, below a certain limit giving spontaneous developability, the less the added number of silver atoms necessary to make the grain developable. Hence the less the exposure required for this and the greater the apparent sensitivity of the grain. They also consider that the variation of the photographic sensitivity with temperature presents a further difficulty. The sensitivity at the temperature of boiling liquid oxygen is apparently still too high to agree with an electrolytic photoconductance effect which may be expected to be vanishingly small at this temperature. This objection again ignores the effect of the size of the pre-existing speck. Only if sensitivity specks were totally absent would the temperature coefficient of photographic sensitivity be comparable with that of electrolytic photoconductance.

Molecular Weight Determination in Camphor Solution.

IN view of the increasing use of a certain excellent and convenient procedure for the determination of molecular weights of substances cryoscopically in camphor solution, the observation should be made that the usual manner of reference to the method in our chemical journals scarcely bestows credit where it is most due.

In the year 1912 Jouniaux,[1] as a result of his "Étude de quelques mélanges binaires contenant du camphre", pointed out that "le camphre présente donc les qualités requises d'un bon solvant cryoscopique". Soon afterwards he published a paper,[2] entitled "Sur l'utilisation du camphre comme solvant cryoscopique", in which he noted the advantage that "un thermomètre ordinaire gradué en degrés" was quite satisfactory for the determinations of the necessary melting points.

In 1922 Rast,[3] without reference to previous work, suggested that the determination of melting points of solutions in camphor of about 10 per cent strength (which, unlike stronger solutions, are seen from Jouniaux's results to exhibit sharp melting points) could conveniently be made in capillary tubes in the ordinary way. This was his only essential innovation.

Rast further (without discussion) adopted 400 as the molecular lowering of freezing point for camphor, calculating this value from melting points of salol-camphor mixtures given in Landolt-Börnstein-Roth (4th edn., p. 556) which themselves are taken from a paper by Caille.[4] Jouniaux (loc. cit.) had previously deduced a higher value, namely, 498. The latter figure seems preferable, not only because camphor is known sometimes to combine with phenols,[5] but also because it is subject to an independent confirmation.[6] From van 't Hoff's relation the latent heat of fusion is seen to be 8·24 cal. Calculated from vapour pressure determinations of camphor by Ramsay and Young, Allen, and Vanstone, combined with a knowledge of the specific volumes of camphor in the liquid and solid states, a value of the latent heat of fusion is obtained actually *identical* with that deduced from van 't Hoff's equation. Better verification could not be desired.

Chemistry and Plant Protection.

To remedy the inadequacy of present-day insecticides and fungicides in the control of crop pests and diseases, two courses are open—the discovery of new insecticidal and fungicidal substances, and better utilisation of existing materials. In this second alternative the chemist has assisted, for example, in determining the one or more active constituents of complex mixtures such as tar oils, lime sulphur, and pyrethrum extract, and particularly in evolving methods of standardisation. The biologist, however, whilst continuing to look to the chemist for the provision of fresh materials, is inclined to forget what knowledge of existing fungicides and insecticides the chemist has already provided. With painful frequency, reports of trials appear in which the materials tested are inadequately described, though knowledge of the probable active constituents and their estimation is available. By failing to employ this knowledge in his field work the biologist obtains results which, lacking

in essential details, cannot be reproduced or turned to use by other workers.

To describe a spray as "ammonium polysulphide (0·5 per cent)" without giving the composition of the ammonium polysulphide solution which was diluted 1 in 200; to give "lead arsenate, 4 lb. per 100 gallons" without particulars of the arsenic content of the paste or powder used; to state "1 per cent White oil emulsion" without giving the characteristics of the oil, are examples of this indifference on the part of the biologist. Such cases of inadequate description are to be met in almost every horticultural periodical, and even in research station reports. As the materials examined are of variable composition, the results are about as valuable as an estimate of size by the familiar method of comparison with a lump of chalk.

It is true that in some cases it is impossible to give sufficient details of composition because analytical methods are not available or our knowledge of the active constituents is insufficient. May not this be due in turn to an absence of demand on the part of the biologist for more accurate knowledge of the materials he finds of use?

Synthesis of Munjisthin.

MUNJISTHIN, a dihydroxyanthraquinone carboxylic acid occurring in *Rubia tinctorum*, *Rubia sikkimensis*, and *Rubia munjistha*, has been synthesised by us in the following way:

2 chloro-6-methoxy toluene (Ullmann and Panchaud; *Annalen*, 350, 108; 1906) is condensed with phthalic anhydride in presence of aluminium chloride giving 2′ chloro-3′ methyl-4′ methoxy-benzoyl-2-benzoic acid (M.P. 202° C.), which on treatment with sulphuric acid gives 2 chloro-3 methyl-4 methoxy anthraquinone (M.P. 197° C.). On demethylation with anhydrous aluminium chloride this gives 2 chloro-3 methyl-4 hydroxy anthraquinone (M.P. 324°-325° C.). On oxidation with nitrous acid in presence of boric and sulphuric acids according to the method of Farbenfabriken vorm. F. Baeyer and Co. (D.R.P. 273341) the chloro-hydroxy-methyl-anthraquinone is converted into dioxyanthraquinone carboxylic acid (M.P. 231°) (cf. Ullmann and Schmidt: *Ber.*, **52**, 2111; 1919), the melting point of which is not depressed by admixture with natural munjisthin obtained from *Rubia munjistha*.

The paper is being communicated to the *Journal of the Indian Chemical Society*.

Three years ago one of us (P. C. M.) had the pleasure of communicating to NATURE (Nov. 19, 1927, **120**, 729) the "Synthesis of Rubiadin".

Experiments on Binaural Sensations.

IN experiments carried out in this Institute we have investigated some of the points raised by Mr. Humby in his letter published in NATURE of Nov. 1.

Differences either of intensity or of phase (time) may be concerned in binaural localisation of sound. It is true, as Mr. Humby says, that it is difficult to design apparatus for phase variation in which intensity changes are completely eliminated; on the other hand, it is possible to determine these changes, and even to balance the effect of a phase shift against that of a difference of intensity.

We have carried out experiments of this kind and find that the variation of intensity required to counterbalance the effect of a given phase (time) shift is very much larger than that which is unavoidably associated experimentally with that shift.

Liquid Drops on the Same Liquid Surface.

IN two previous papers,[1] I have mentioned that water at ordinary temperature is not a suitable liquid for forming "liquid drops floating on the same liquid surface". In August 1930, however, I observed at Den Kund (Dalhousie hills), at a height of about 1000 ft. above the sea-level, that water is quite a suitable liquid for easy formation of either primary[2] or secondary drops. The life of these drops is also found to be longer. The splashing gives easy formation of secondary drops of quite a long life. The temperature of the water was about 34° F. The surface tension of water at this temperature is 76·53 dynes per cm., and viscosity 0·0179 c.g.s. units.

Upper and Lower Palæolithic Man at Kirmington, North Lincolnshire.

AS the result of recent investigations carried out by me at Kirmington, I am able to state that the uppermost or 'Brown' Boulder Clay contains flint artefacts of Upper Palæolithic types, whilst from the immediately underlying Glacial (cannon-shot) Gravels I have recovered a series of derived flint implements of Early Mousterian type. Similar implements, in a still more derived condition, I found in the shingle gravel which overlies the estuarine warp.

These observations, which I propose to describe in full at a later date, confirm the conclusions arrived at by Lamplugh and by me with regard to the sections at Danes' Dyke on Flamborough Head. The variableness of the "Brown Boulder Clay" at Kirmington might profitably be studied by geologists.

Traces of Metals in Animal Tissues.

To the various elements referred to by Messrs. H. M. Fox and Hugh Ramage in their interesting letter published in NATURE of Nov. 1, there are three which may still be added.

Vanadium is stated to occur in considerable quantities in certain Ascidians; arsenic—sometimes in not inconsiderable amounts—is almost ubiquitous; and I have myself recently observed the unexpected presence of antimony. With regard to this last-mentioned element, I hope to publish a communication as soon as the work is completed.

The Synthetic Activities of the Cell.*

By Prof. H. S. RAPER, C.B.E., F.R.S.

UNLIKE the chemist, the animal cell has a very limited choice of raw materials from which synthesis must start. These are the components of the common foodstuffs. When they have undergone the preliminary processes of digestion they provide in all about thirty substances which may be regarded as available for the building up of new compounds by the cell. Given these raw materials, can we in every instance indicate which is the likely starting-point for the synthesis of substances the constitution of which is known or partly known? This question must still be answered in the negative for such well-known products as cholesterol and the unconjugated acids of bile.

With the purine bases, which are components of nuclear material and therefore present in all cells, this question of indicating the probable raw material for their synthesis must also be answered in the negative, but with less emphasis than in the case of cholesterol and the bile acids. The amino acid histidine, which contains a five-membered ring similar to that found in the purine bases, is their most likely precursor on structural grounds. But we have as yet no experimental evidence that indicates clearly their origin from this amino acid in the body. Until this has been proved, it is perhaps useless to speculate as to the chemical processes involved in the transformation.

An example of a synthetic product which bears a fairly close structural relationship to two of the amino acids which are found in proteins is adrenaline. These two amino acids, phenylalanine and tyrosine, have practically the same carbon skeleton as adrenaline. Either of them might give rise to adrenaline by successive oxidation, methylation of the amino group, and loss of carbon dioxide. That a part of the necessary oxidation process can be brought about by means of an oxidising enzyme, tyrosinase, has already been demonstrated.

If, however, we consider whether a process of this kind, operating in the cells of the adrenal gland under specific conditions, gives rise to adrenaline, difficulties appear. When we remember that the oxidation of one substance may only take place if another is reduced; that a reaction taking place in one compound may only be possible when some other reaction takes place alongside it—in other words, that in the living cell there is a continuous and complex interplay of chemical reactions—then it is not surprising that the discovery of the mechanisms by which adrenaline is formed, although a simple problem at first sight, is probably in reality very complicated.

The case of thyroxine is comparable with that of adrenaline. Thyroxine is a relatively simple chemical substance which could conceivably be produced by the oxidation of diiodotyrosine. The last-named compound has recently been shown to be present in the thyroid gland and this makes the presumption that it is the mother substance of thyroxine all the stronger. Yet it has not been demonstrated either *in vitro* or *in vivo* that thyroxine may be produced from diiodotyrosine.

We may now pass on to consider a process in which the raw material is known with certainty but the chemical reactions by which the synthesis takes place are relatively obscure. I refer to the production of fat from carbohydrate. Lawes and Gilbert, in their classical experiments at Rothamsted on the fattening of farm stock, showed indubitably that animals can produce fat from starch. Since the starch is converted into glucose in the alimentary canal prior to absorption, we may consider glucose as the starting-point of the synthesis.

The most likely chemical explanation of the origin of the fatty acids is that they are built up, two carbon atoms at a time, from some simple reactive substance which is first produced by degradation of glucose. Acetaldehyde and pyruvic acid have both been suggested as probable participants in a reaction of this kind, the former condensing with itself as in the well-known aldol condensation, the latter either with acetaldehyde or with some higher aldehyde containing an even number of carbon atoms produced in the earlier stages of the reaction. By both of these methods it has been shown that *in vitro* aldehydes with an even number of carbon atoms in a straight chain can be built up step by step and these by oxidation can be readily converted into the corresponding fatty acids. Unsaturated linkages in the chain may be produced by either method, so that this requirement in the hypothetical synthetic method is also satisfied. Further, the condensation takes place in weakly alkaline solution or under the catalytic influence of certain organic bases, so that drastic treatment is not necessary to bring out the reaction. So far, this evidence for the mechanism of synthesis of the fatty acids is purely chemical and the grounds on which it can be put forward are largely chemical ones. It is known also that acetaldehyde and pyruvic acid, the intermediates postulated in this hypothesis, can be produced in the body. But there the question rests for the present so far as higher animals are concerned. When we know what the conditions are which set the process of fat synthesis going, and when we are able to reproduce them at will in animals, it may be possible to determine what are the intermediate substances concerned.

More success has been achieved by a study of the formation of fatty acids in micro-organisms. Bacteria which form butyric acid from glucose have been found to produce in addition both lactic acid and acetaldehyde. These same bacteria will also produce butyric acid from pyruvic aldol though not from aldehyde ammonia, aldol, or pyruvic acid itself. Neuberg and Arinstein, who investigated this type of fermentation, conclude that pyruvic aldol is the precursor of the butyric

* From the presidential address to Section I (Physiology) of the British Association, delivered at Bristol on Sept. 4.

acid when it is formed from carbohydrate. But it has also been shown that in this so-called butyric fermentation fatty acids containing an even number of carbon atoms higher in the series than butyric are formed, namely, hexoic and octoic acids. This makes it appear probable that the processes by which these lower members of the series of fatty acids are formed in bacterial fermentation may be the same as those by which higher members of the series are formed in animals.

The intensive study during the last few years of the processes of alcoholic fermentation and the chemical events which occur in muscular contraction has revealed such close similarities that we are becoming forced to accept the view that certain fundamental activities of the living cell, whether animal or vegetable, may be carried out by an almost identical mechanism. It may therefore be that we shall eventually discover the reactions responsible for the synthesis of fat in animals by investigating the processes by which it occurs in vegetable forms, such as bacteria or moulds.

Even if these reactions be the right ones, the problem still remains as to how they are accurately controlled within the cell. Some of the substances concerned in them are diffusible and very reactive, and we should have to explain how diffusion away from the site of reaction is prevented. To overcome difficulties of this kind it is becoming common to invoke the intervention of surface forces. There is, however, not much experimental evidence as yet which helps us to explain by such intervention the mechanism of synthetic processes even of such a simple kind as the reversal of an enzyme action.

Freundlich in his Liversidge Lecture to the Chemical Society last year described experiments on the influence of charcoal in modifying the velocity of certain reactions. These showed that the stability of a substance on a surface may be greater than in homogeneous solution under similar conditions. It must be borne in mind, however, that in these experiments very large quantities of charcoal were used compared with the amounts of the substances the equilibria of which were being studied. So much so that in the reaction in alkaline solution the bromoethylamine was practically completely adsorbed and the reaction was taking place entirely on the charcoal surface. Can one postulate such conditions during the continuous synthesis of substances in the cell, glycogen from glucose, for example? It seems to me that to explain the rapid accumulation of synthetic products such as fat or glycogen which we observe in cells, something more than a shift in the equilibrium of the reactions due to surface forces is necessary. Such a condition favouring synthesis could only operate for a time until the surface became saturated. We must therefore postulate some additional mechanism whereby the synthesised product is removed from the sphere of action, for if it diffused off the surface again it would be subject to the equilibrium conditions which are present in the solution. It may be that the arrangements in the cell are such that only small amounts of the substrate are dealt with at a time, so that complete synthesis is achieved and the synthetic product removed.

We have also to consider how the synthetic product is protected in the cell from the disruptive agencies which exist there. Arrangements for this purpose must be present, since we know that substances may accumulate in cells which contain enzymes that hydrolyse them. Whatever these arrangements are, they appear in certain instances to be closely associated with the life of the cell, for after death they cease to operate and the synthetic product is again broken down. However difficult it is to form a conception of them, it may be necessary to do so, since they must form a part of any system which is put forward to explain synthesis as a result of the intervention of surface phenomena.

We may now consider two syntheses in which there is little or no doubt about the raw materials or some of the chemical reactions involved. These are the production of glycogen and of proteins.

It has been proved that when glycogen breaks down in the liver it gives rise to glucose. Lohmann and also Barbour have succeeded in obtaining glycerol extracts of liver and muscle which hydrolyse it, but the product appears to be a trisaccharide and not glucose. No enzyme which by itself hydrolyses glycogen to glucose has yet been obtained from animal tissues. It is of interest that pancreatic and salivary amylase produce isomaltose from glycogen. These results suggest that there may be some configurational difference between glycogen and starch which accounts for their difference in behaviour with diastatic enzymes. Be that as it may, it appears natural to assume that the synthesis of glycogen from glucose in the cell is brought about by the simple reversal of a hydrolysis which may be catalysed by enzymes under appropriate conditions. These conditions have, however, not yet been realised *in vitro*. Barbour was unable to demonstrate any synthesis of glycogen from the trisaccharide produced by the muscle enzyme even in highly concentrated solutions.

This failure to obtain evidence of the synthesis of glycogen from the products of its hydrolysis makes it legitimate to consider whether we are right in adopting the orthodox view that the synthesis of glycogen from glucose in the living cell is brought about by a reversal of action of the enzyme or enzymes which hydrolyse it. There are other facts which merit consideration in any discussion of its mode of synthesis in the body. When an animal is fed liberally with glucose or fructose, it converts a part of them into glycogen in the liver. The evidence for this is indubitable. It implies, therefore, either a conversion of fructose into glucose before the condensation to glycogen occurs, or a conversion of both into some common form of hexose which then undergoes the condensation. Further, there is a considerable amount of accredited evidence that many substances not belonging to the sugar group can be converted into glucose in the animal body. Such substances, therefore, must be regarded as potential glycogen formers. Whatever the processes

may be which eventually result in the production of a hexose from these diverse substances, the most remarkable thing about them, to my mind, is that the hexose is always *d*-glucose. We have no satisfactory explanation for this striking stereochemical performance, but the facts suggest that the condensation of the two—or three—carbon units to a hexose is brought about under such specific conditions of strain that only the *d*-glucose configuration can result, much as coins must be minted in a definite mould to become currency.

A consideration of all the data which have been accumulated regarding the synthesis of glycogen makes it probable that more than the mere reversal of enzyme action is concerned. It is certain that the cells in which it occurs must be supplied with oxygen. Fletcher and Hopkins showed with muscle that its structure must be maintained, and with liver the synthesis certainly only takes place in the intact organ. Do not these facts point to the conclusion that it is only the living cell that can bring about this synthesis ? And if this be so, cannot we go further and suggest that the substances from which glycogen is produced, or bodies derived from them, must first become bound up with, or at some stage form an integral part of, the living structure before they are converted into glycogen ? The evidence at least suggests that some such conception of the process may not be far from the truth.

We may now pass to the consideration of the synthesis of proteins. In the early part of this century, due largely to the elegant methods introduced by Emil Fischer, rapid advances were made in our knowledge of the structure of proteins. These advances led to a picture of protein structure which has become generally accepted, namely, that the protein molecule is formed by the union of amino acids through an amide linkage.

The investigation of the structure of proteins, which are closely allied in origin, composition, and general chemical behaviour by immunological and in part by chemical methods, has taught us how intricate the mechanism must be by which they are built up. The facts brought out by the classical work of Dakin and Dale on the albumin of the duck's and hen's egg serve to exemplify this. The only chemical difference that could be shown between these two proteins was concerned with the disposition in the molecule of some of the leucine, aspartic acid, and histidine. But when used as antigens in the anaphylactic reaction they were markedly specific.

These results indicate that the chemical structure of the molecule is different in proteins which are very similar both in general chemical properties and in biological origin. They suggest that the protein molecule produced by a particular type of cell is always built up in a distinctive and, so far as we can determine, an unvarying pattern. We may deduce from this that although the general method of protein synthesis—that is to say, the mechanism by which amino acids are joined up —may be the same in all cells, yet there must be arrangements in the cell which enable only one particular, final pattern to result from the synthesis.

What are the methods by which the amino acids are caused to combine ? The use of proteolytic enzymes in an attempt to bring about synthesis under conditions which have been partially successful with other substances has often been tried and nearly as often has failed. Two examples of protein synthesis by enzyme action have been described. The most acceptable of these is Taylor's production of a protamine by a glycerol extract of clam liver from the products of its complete hydrolysis. The other is the preparation of so-called plasteins from the products of the partial hydrolysis of certain proteins by pepsin. A comprehensive review of the subject of plastein formation by Wasteneys and Borsook, who have themselves made notable contributions to this problem, has led them to the belief that in this phenomenon we have a true resynthesis of protein from some of the more complex of its hydrolytic products.

Even if this be accepted as a possible explanation, it still leaves many questions regarding protein synthesis unanswered, and not the least difficult of these is the problem of how the separate amino acids are brought together to form the specific proteose substrates which one must postulate as combining—and in a definite order—to produce the particular protein which is characteristic of the cell which synthesises it.

The process by which the substance of the cell is increased, the building up of protoplasm, is one which must be closely allied to protein synthesis, since the material we call protoplasm is constituted for the greater part of amino acids, united, so far as can be ascertained, by the same sort of linkage that we find in proteins. The protoplasm of the dead cell responds to all the tests by which we identify protein, it is subject to the action of hydrolytic agents in the same way, and yields identical products when hydrolysed.

Ought we not therefore to look for some of the mechanisms of protein synthesis in the processes which operate when the living cell grows, and can we by any stretch of imagination account for this by a reversal of the action of one or more hydrolytic enzymes ? It appears inconceivably difficult to do so. The extreme specificity of the reaction, which necessitates that at a given phase of the synthesis one particular amino acid and that one alone can be added as the next link in the molecule, requires such a multiplicity of enzymes and such a remarkable degree of control of their action as to be almost outside the range of probability. When we remember, however, that one of the prime attributes of life is that it is a dynamic condition, it does become possible to form a conception of protein synthesis in relation to that fact. The experiments of Willstätter and others have shown that to some extent the specificity of enzymes is accounted for by the 'carrier' with which they are associated. It is not inconceivable that a catalyst capable of bringing about the union of amino acids in the living cell and ultimately fashioning its protoplasm may be attached to or associated with a

'carrier' which, instead of having a fixed configuration, as with the enzymes that we can extract from the dead cell, has one which is continually varying, this dynamic state being characteristic of the living material of the cell.

If, further, we could assume that the variations in the configuration of the carrier were cyclic, always going through a definite series of phases, it might be possible to account for the fact that at any particular phase of the cycle the configuration would be such as to favour the synthetic union of one particular amino acid rather than any other because of its spatial arrangement. The assumption of cyclic changes in simple or complex living organisms is not new in physiology, and it is not unlikely that they occur in parts even of the cell itself.

The possibility that protein synthesis is associated with some part of the cell which is undergoing cyclic changes, and is thus alive, raises the interesting question of the site of this and possibly other syntheses, such as those of fat and glycogen. Are all parts of the cell, that is to say, both nucleus and protoplasm, to be regarded as alive in the sense I have indicated, and therefore to be considered as regions in which syntheses depending on life can be brought about?

It is necessary not to confuse the terms irritability and life. It is true that what we term irritability is usually taken to imply that the tissue which shows it is living; but taking the nerve fibre as an example, it would appear that the maintenance, for a time at least, of the irritability of protoplasm and its restoration when it has disappeared—but not irreversibly—does not require the presence of the nucleus. It may require oxygen or the presence of certain ions, but this may merely mean that the labile state of the protoplasm has been upset by the products of the cell's activity, and removal of these will restore it to its irritable condition.

We have no evidence that irritability as a manifestation of what we call life is more than the possession of extremely labile structures, sensitive to minute environmental changes. The nucleus, on the other hand, is essential to the continuous life of the cell and its growth. It appears also to determine very largely the magnitude of the respiratory processes which occur in it at rest, though not necessarily the excessive respiration observed in the recovery from functional activity. Can we therefore go so far as to say that the nucleus is the seat of those synthetic activities of the cell which appear to depend on its living character rather than on its irritability, or have we to regard the protoplasm as equally living, so that it is able to reproduce itself and in addition bring about such syntheses as those of fat and glycogen?

There is something to be said in favour of the idea that the protoplasm is not living in the sense in which the nucleus is, and therefore is less likely to be the seat of certain synthetic processes. It is, I think, quite a tenable view that protoplasm is made up, largely but not entirely, of combinations of amino acids such as we find in the proteins, and that it is synthesised by the nucleus to serve special as well as certain general requirements. These special requirements must and do vary greatly with each type of cell.

Consider the mammalian erthroblast. The principal substance in its protoplasm is the protein hæmoglobin. It is doubtful whether this cell exists except to produce hæmoglobin. When it has matured, the nucleus degenerates and disappears, leaving the red blood corpuscle. Along with this the respiratory activity of the cell practically disappears too, and there is not much discoverable in it except hæmoglobin. It is certainly now not living in the sense in which its progenitor, the erythroblast, was. Is it not reasonable to suggest, therefore, that the production of hæmoglobin as the erythroblast grows and matures is a function of the nucleus and not of the protoplasm of this cell? All semblance of further synthesis of hæmoglobin certainly disappears when the nucleus goes. The adoption of such a view does not imply that having produced the protoplasm of a cell the nucleus has nothing more to do with it. We know that in some indefinable way the nucleus in most cells controls the structure of the protoplasm and maintains its lability, but we have no knowledge as yet of the mechanism by which this is brought about.

One property of proteins, which may account in a general way for the presence of protein-like structure in protoplasm, is their buffering power. The nucleus is probably the most labile part of the cell. The chemical reactions proceeding in it may demand an environment that has to be finely controlled as regards changes in reaction or the concentration of certain ions. The protoplasm may thus serve as a protective layer between the nucleus and the external world, guarding it from changes which would otherwise terminate its existence. The known properties of the proteins, both chemical and physical, may be useful to this end, to which they are almost ideally suited.

Even if we can accept as possible the unorthodox view that the nucleus is the only living part of the cell, and is therefore the only part that can bring about syntheses which depend upon life, it does not solve our difficulties in explaining how they are achieved. It merely narrows down the possible sites in the cell in which they occur. The nucleus itself is a complex structure, and we have as yet few experimental methods for elucidating it. Most biologists would, I think, agree that the cell has arisen by a process of evolution from something simpler and eventually from non-living materials. It cannot have come as a 'bolt from the blue'. If we regard the nucleus as the only living part of the cell, then we may justly regard the protoplasm as something that has been acquired or developed in the process of evolution and is now necessary to its existence. We do not know definitely, however, of nuclear material which is living and devoid of its protoplasmic envelope unless such an arrangement is present in the bacteria. But the investigation of filterable viruses has given an indication that material possessing the

prime attribute of life, namely, the power of reproducing itself, exists possibly in simpler forms than we find in the smallest visible organisms.

If we agree that the cell has evolved from something simpler, then we might expect to find such elementary forms of life coexisting with it, did we but know how to look for them. The filterable viruses may represent such forms, and their chemical characters may resemble those that we find in the nucleus of the cell. The ability to synthesise protein may be a property which living material only acquired at a late stage of its evolution, and that property may be one which in the process of time has come to be essential for the maintenance of the complex structure of the nucleus as we see it to-day.

An Anthropometric Investigation on Twins.

THE latest contribution to the now considerable mass of literature bearing on the resemblances and differences between twins is a valuable memoir by Dr. Percy Stocks ("A Biometric Investigation of Twins and their Brothers and Sisters", *Annals of Eugenics*, vol. 4, April 1930). The tests and measurements were made during 1925-27 on twin children and their brothers and sisters in elementary and central schools of the London County Council, the ages of the children ranging from three to fifteen years. The characters considered in the present memoir—others will be dealt with later—include height; weight; length, breadth, and horizontal circumference of head; interpupillary distance; blood pressure; pulse rate; respiration rate; eye colour; hair colour; facial resemblance on an arbitrary scale of four classes; and finger-prints. The total number of children examined was 832 (392 boys and 440 girls), of whom 563 were members of twin pairs, 7 were surviving members of triplets, a few were odd twins who had a brother or sister at school, and the remainder were either siblings of twins, or pairs of siblings unconnected with twins, the latter being necessary to form a comparative group.

An investigation on such data is obviously not a simple matter. It is desired to compare (1) monozygotic twins, (2) dizygotic twins, (3) other siblings, with regard both to individual measurements (means, standard deviations, etc.) and correlations or differences between pairs. As was first pointed out recently by Dr. R. A. Fisher, the proportions of monozygotic and dizygotic twins amongst pairs of the same sex may, *if a character is normally distributed*, be estimated from the available data and the frequency distribution of differences analysed, but this does not give wholly what is wanted. Separation of monozygotic from dizygotic pairs on the basis of facial resemblance only is by no means so satisfactory as the unpractised observer might suppose: Dr. Stocks concludes (p. 81) that only about two-thirds of like-sexed twins can be at once separated by facial resemblance into two groups labelled 'identical' and 'fraternal', and even for these groups other evidence suggests that the diagnosis is really incorrect in a small proportion. The final conclusion reached is that finger-prints form the best fundamental test, with anthropometric measurements (height and head measurements) to decide doubtful cases, and definite rules are laid down for the purpose.

Assuming this analysis made, there is a further trouble due to the great range of age amongst the children observed, and differences of sex. Were the data subdivided into age and sex groups, the numbers in each group would be too few for valid comparison. This difficulty is surmounted by converting all measurements to standard age and sex, and only these converted or 'corrected' measurements are used. Further to increase the virtual numbers on which a comparison is based, by using relative deviations different measurements may be pooled together; for example, all the 'static characters', as Dr. Stocks terms them—height, the three head measurements, and interpupillary distance.

Finally, in an investigation of this kind, errors of measurement, and the errors involved in the fact that only single measurements were taken of such fluctuating characteristics as pulse and respiration rates, are of much more importance than they would be in most anthropometric investigations. To obtain information on these points and enable correction to be made, repeated observations were carried out on five individuals for fifty days. How important is this correction for errors and day-to-day variation may be seen from the fact that correlations between siblings are raised by about 90 per cent for pulse rate, 40 per cent for respiration rate, 20 to 30 per cent for blood pressure, though only by much smaller amounts of 0·25 to 2 per cent for the dimensional measures.

Making these corrections, mean correlations for the three groups work out as follows (Table XI., p. 103):

	Non-twin siblings.	Dizygotic twins.	Monozygotic twins.
Height	0·49	0·56	0·95
Head dimensions	0·45	0·45	0·83
Weight	0·38	0·46	0·94
Blood pressure	0·46	0·39	0·81
Pulse and respiration	0·27	0·39	0·86
Aggregate of 10 characters	0·42	0·47	0·85

The results suggest that correlations for non-twin siblings do not differ appreciably from those for dizygotic twins. Hereditary constitution appears to be more important in comparison with environment in regard to height and weight, rather less so in regard to head measurements, still less in regard to blood pressure, and least of all in pulse and respiration rates. Dizygotic twins are, in these data, on the whole inferior to their brothers and sisters in the physical measurements, but this is certainly not the case with monozygotic twins, except perhaps as regards weight.

Supplement to NATURE

No. 3185 NOVEMBER 15, 1930

Science Medals of Great Britain, Ireland, and the Dominions.

THE absence of any connected and inclusive account of the terms of the trusts and foundations under which the science medals of Great Britain, Ireland, and the Dominions are allotted, whether also of yearly, biennial, triennial, or of longer interval of distribution, forms sufficient reason for an attempt to fill this gap by bringing together information upon the different awards. While various academies and societies, incorporated and other, have from time to time instituted gifts of this description, information regarding them is often scanty, and, moreover, is not well known. It is proposed to divide the awards in three classes: (1) General; (2) Physical and Mathematical Sciences; and (3) Biological Sciences (including Geology and Geography).

For many years, in countries where scientific studies have been pursued, the award of gold, silver, or bronze medals, at varying intervals, in recognition of notable researches, has been accepted as an honourable and tangible expression of contemporary opinion regarding their character and worth. In addition, the practice is very generally observed of allocating gifts of money—in other words, *prizes*—for work in identical fields, a course which it would be mere affectation to deny is substantially parallel in purpose with the custom of awarding medals. In any event, both methods have been practised by world-known academies and societies.

In Great Britain, compared with other countries, the award of medals for past and current achievements in science finds fuller favour, it must be confessed, than that of monetary prizes, though, it is true, medals are frequently accompanied by the gift of balances of funds associated with the respective foundations. But here, such allotments are very moderate in amount, scarcely to be considered as prizes. The British tendency is mostly in the direction of the establishment of fellowships and post-graduate endowment, whereby the pursuit of various branches of natural knowledge may be provided for, or definite research work promoted. However, no rule exists, and societies and individuals are free to consult their own dictates, and form their own opinion regarding the kind of stimulation and the quality of effort it is desired to continue or inaugurate.

Certain considerations respecting types of science medals may be referred to, though at the risk of being didactical. A well-proportioned artistic medal appeals to persons of good taste and discrimination, especially if, in appropriate manner, it denotes its aim and purpose. An example complying with this standard, executed in silver or bronze, is preferable to a medal of poor interest and intent produced in the gold medium. In one case design is paid for from available funds; in the other, gold value. What might prove a legitimate source of pleasure and pride to the recipient may be sacrificed for a gift-horse in metal, weak, or frankly ugly. There are, however, limiting difficulties which cannot be overlooked. Mixed committees charged to discuss and decide upon the institution of medals not infrequently display a regrettable lack of judgment. At the end some compromise is inevitable. Yet in the service of science, medallic art may find surviving compensations, notwithstanding these pains and penalties.

Generally it is incumbent on the artist-designer of a modern science medal to portray on his obverse the lineaments of some person whose achievements are connected with the *raison d'être* of foundation. If, in regard to the reverse, his hands are not unduly tied, symbolism, imagination, and poetic fancy have scope for exercise. The reverses of medals of earlier centuries present an infinite variety of design and device. Most of them drew inspiration, in some form or other, from Greek and Roman coins, where the figures of deities with their attributes were symbolised. They serve the designer of the science medal in that he may associate pagan derivatives with modern developments of philosophy and natural knowledge. On the reverse of the Nobel gold medals awarded for physics and chemistry, we see Nature personified as the goddess Isis. But the reverse of the gold medal struck in 1907 by the Royal Swedish Academy of Sciences to commemorate the two hundredth anniversary of the birth of Linnæus depicts a student dissecting a flower; the art here is wholly pictorial in conception.

An authoritative critic has remarked that "more than anything else, the medal in its restrained limits, proves that art has nothing to do with mere quantities, and that within the small circle of a disc of metal the great artist can make his appeal as unerringly and as powerfully as upon square yards of canvas". It is in chief to French artists, working during the period since 1870, that we owe much that is in agreement with the foregoing comment. The medals of David, Chaplain, Dubois, and Roty commemorate men and women and signalise great events after the fashion of the traditions of the early Italian and German designers, and over and above is fancy and charm of detail. The late M. Roty stood at the head of

these artists. In a letter which the writer received from him in 1898 he says: " The rectangular form of medal was only adopted a few years ago. I was the first to re-employ this form, and it was so successful that my colleagues in France and in other countries followed my example. The habits of sheep are very much the same in all countries." The well-known rectangular plaquette of Pasteur was by M. Roty.

Medals of satirical implication, designed to provoke ridicule, were in circulation at the end of the sixteenth and throughout the seventeenth centuries. In the most part they bore reference to current and acute political and religious controversies, and hence do not concern us here. But it is worthy of note that science does not appear to have suffered from the satire of the die-sinker. Even at the time of Jenner's discoveries, though many lampoons and caricatures deriding the smallpox preventative were published, no satirical medal was issued.

In the preparation of modern medals the usual procedure of the artist-designer is to make a model in modelling wax on slate, to scale. From this a cast in plaster is taken, which may be worked over and serve as the final model. Bronze casts can now be obtained by the expert founders. If a struck medal is required, a cast in steel is made from the plaster model, and from it convex dies in soft steel are produced by the ' reducing machine ' ; after hardening, they serve then their mission, which is to punch out the concave dies for striking the medal.

Reference was made recently in this journal (Oct. 5, 1929, p. 557) to the observation of Gurwitsch that when the tip of one actively growing onion is brought near to the tip of another growing onion, whether end-on or broadside-on, mitosis is stimulated in the latter in the neighbourhood of the growing tip of the former; from which is deduced or foreshadowed an attractive hypothesis of biological rays and fields of force, a counterpart of the fields of force of physical science. Can it be that the medallic art of a distant future will have to consider the onion seriously; that whereas we already have *Primula* and *Nepenthes* (Darwin medal, Royal Society), a future designer may have to include *Allium* in his list of possible delineations?

I. General.

Royal Society of London.

Copley Gold Medal.—Founded in 1736, arising from a legacy derived in 1709 from Sir Godfrey Copley, Bart., F.R.S., and for some time used otherwise than in medallic gifts. Bestowed annually upon the living author of such philosophical research, either published or communicated to the Society, as may appear to the council to be deserving of that honour. No distinction of nationality governs allotment.

Royal Medals.—Two gold medals were founded by King George IV., the grants being continued by successive sovereigns. They are awarded annually (subject to royal approval) for the two most important contributions to the advancement of natural knowledge, published originally in His Majesty's dominions within a period of not more than ten years, and of not less than one year of the date of the award. The obverse of each medal bears the head of the reigning sovereign.

See, for other medals awarded by the Society, Physical and Mathematical Sciences and Biological Sciences sections.

British Association for the Advancement of Science.

Montreal Medal.—During the Montreal meeting (1884), the decision was taken to commemorate the visit by founding a bronze medal for annual award by McGill University for proficiency in applied sciences. The obverse bears the head of James Watt.

Toronto Medal.—From the income of a fund raised by members who attended the meeting (1924), two bronze medals and gifts of books are awarded annually to selected students of the University of Toronto.

South Africa Medal.—To commemorate the visit (1905), a fund was raised among the members who made the journey for the provision and endowment of a medal or studentship for South African students. The medal was struck in bronze from designs by Mr. Frank Bowcher The symbolical figure on the reverse has since served the Association as a badge.

Following upon the meeting in South Africa in 1929, a medal for scientific workers in South Africa not exceeding thirty years of age has been instituted, under an arrangement between the British and South African Associations.

Asiatic Society of Bengal.

Sir William Jones Memorial Medal.—Awarded biennially for Asiatic researches in science. The next award falls due in 1931.

See also Biological Sciences section.

Royal Society of Canada, Ottawa.

Flavelle Gold Medal.—The gift of Sir Joseph Flavelle of Toronto, and first awarded in 1925. It is allotted to fellows of the Society or others for original work in science or literature of especial merit. The medal is not necessarily bestowed annually. Since 1927 it has been awarded only for work in science.

Royal Society of Edinburgh.

Keith Gold Medal.—Instituted in 1820, and awarded biennially, together with a sum of money from the fund, for the most important discoveries in science made in any part of the world, but communicated by their author to the Society, and published first in its *Transactions*. In 1833 provision was made, during any biennial period, for a substantive mode in adjudication. The medal bears the bust of John Napier on the obverse.

Makdougall-Brisbane Gold Medal.—Instituted in 1855 by Sir Thomas Makdougall, Bart., president, 1832–60, and awarded biennially, together with a sum of money from the fund, to such person, for such purposes, for such objects, and in such manner as shall appear to the council most conducive to the promotion of the interests of science. For 1930–31 the medal (and prize) will be awarded for an essay, paper, or other work having reference to any branch of scientific inquiry, either material or mental. Open to all men of science. The obverse of the medal bears the head of the founder.

See also Biological Sciences section.

Royal Irish Academy

Cunningham Gold Medal.—Instituted under the bequest (1789) of Timothy Cunningham, of Gray's Inn, and first awarded in 1796. Medals have not been allotted since 1885, the interest of the fund having been devoted to the publication of memoirs. The head of Lord Charlemont, first president of the Royal Irish Academy, appears on the obverse of the medal.

Royal Society of Tasmania.

Society's Medal.—Founded in 1927 for the recognition of eminence in research, and for work of outstanding merit on behalf of the Society and the State. Awarded at intervals (irrespective of sex). The regulations are restrictive as regards residence in Tasmania and membership of the Society. The medal is oval in shape, and is struck in bronze.

African Society.

Society's Gold Medal.—Founded in 1920 by Mr. Henry S. Wellcome, a member of council, for annual award, in respect of eminent services rendered to Africa. A silver medal was also instituted by him at the same time in recognition of kindred services. The medals are in memorial of Mary Kingsley. The first recipient was Sir Harry Johnston.

Royal Institute of British Architects.

Grissell Gold Medal.—Awarded annually for meritorious work in constructive architecture.

The Institute has a series of medals at its disposal for the encouragement of various branches of architecture. We select one which bears relation to questions mutually concerning the architect and man of science.

Royal Society of Arts.

Albert Medal.—Instituted in 1862 as a memorial of H.R.H. the Prince Consort. Struck in gold, it is awarded for "distinguished merit in promoting Arts, Manufactures, and Commerce". The first bestowal was made in 1864 to Sir Rowland Hill, and annually since, irrespective of the nationality of the recipient. The obverse bears the head of the Prince Consort.

The Society also awards annually ten or twelve silver medals for the best papers read during the session.

Royal Scottish Society of Arts.

Keith Medal.—The Keith Prize was founded in 1833 by Alexander Keith, to be applied in sums of money or medals in rewarding inventions, improvements, or discoveries in the useful arts. The award frequently consists of a medal together with a sum of money.

Brisbane Medal.—The Brisbane Prize was instituted in 1856 by Sir Thomas Makdougall-Brisbane, Bart., to be awarded either in a medal or a medal along with plate, books, or money, to the authors (or inventors) of communications of merit.

Hepburn Medal.—The Hepburn Prize was founded in 1862 by John Stewart Hepburn, for inventions and communications approved by the Society. The award (annual or biennial) frequently consists of a medal together with a sum of money.

Society's Medal.—Awarded at the discretion of the council as a means of recognising special services rendered to the Society, or in such other manner as the Society may approve. The medals may be struck either in gold, silver, or bronze.

Royal Asiatic Society of Great Britain and Ireland.

Society's Gold Medal.—Instituted in 1897 to commemorate the sixtieth year of reign of Queen Victoria. Awarded triennially in recognition of distinguished services in Oriental research.

Burton Memorial Medal.—Instituted in 1925 to celebrate the birth centenary of Sir Richard F. Burton. Awarded triennially in connexion with a lecture dealing with the life of Burton, and his contributions to Oriental literature and studies of Eastern life and character. Also in respect of his explorations and travels and geographical achievements, or those of other famous explorers whose travels have led to an increase of geographical and ethnological knowledge. The medal is struck in silver; the obverse bears the head of Burton.

Royal Empire Society (formerly Royal Colonial Institute).

Society's Gold Medal.—First awarded in 1914 for a monograph on an Imperial subject. After 1915 the gift fell into abeyance during the remaining period of the War. On its revival in 1925, it was decided to award the medal for the work adjudged to be the best recent book on a subject of Imperial interest.

Royal Society of Literature.

Society's Gold Medal.—The Society was founded by George IV. in 1823, and incorporated in 1825. The first award of a medal was made in 1825 and bestowed upon James Rennell, F.R.S., the geographer. Awards are made at varying intervals. The obverse of the medal bears the head of George IV.

Royal United Service Institution.

Institution Gold Medal.—Founded in 1874, and awarded annually for the best essay on a naval and military subject alternately. The obverse bears the head of Athena.

Chesney Memorial Gold Medal.—Founded in

1900, and awarded at intervals to "the author of any specially eminent work calculated to advance military science or knowledge in the Empire". The medal was instituted to commemorate the services of General Sir George T. Chesney, K.C.B., R.E.

Chester Society of Natural Science, Literature, and Art.

Kingsley Memorial Medal.—Founded in 1877, and awarded "for having contributed materially to the promotion and advancement of some branch or department of Natural Science". The medal commemorates the Rev. Charles Kingsley, founder of the Society. The medal is struck in bronze, and bestowed annually. The obverse bears the head of Kingsley.

Victoria Institute, or Philosophical Society of Great Britain.

Langhorne Orchard Prize.—A silver medal for a prize essay on a subject bearing on science and religion. First given in 1925 and again in 1929. An open Bible is inscribed on one side of the medal.

II. Physical and Mathematical Sciences.

Royal Society of London.

Rumford Gold Medal.—Founded in 1796 by Count Rumford, F.R.S., and first awarded in 1800. Bestowed biennially upon the author of the most important discovery or useful improvement in heat or light during the preceding two years. The medal is also struck in silver; the obverse bears the head of Rumford.

Davy Gold Medal.—Founded in 1869 under the will of Dr. John Davy, a brother of Sir Humphry Davy. Awarded annually for the most important discovery in chemistry made in Europe or Anglo-America. The obverse bears the bust of Davy.

Sylvester Medal.—Awarded triennially for the encouragement of mathematical research, irrespective of nationality, and in honour of the life-work of Prof. J. J. Sylvester, F.R.S. First allotted in 1901. The medal is struck in bronze; the obverse bears the bust of Sylvester.

Hughes Gold Medal.—Founded under the will of Prof. D. E. Hughes, F.R.S., who died in 1900. Awarded annually for original discovery in the physical sciences, particularly electricity and magnetism, or their applications. The medal is allotted without restriction of sex or nationality; the obverse bears the head of Hughes.

See also General and Biological Sciences sections.

Royal Dublin Society.

Boyle Medals.—Founded in 1895, and awarded on the recommendation of the Committee of Science and its Industrial Applications in recognition of scientific work of outstanding merit done by Irishmen, or in Ireland, and not restricted to members. The medals are struck in bronze; the obverse bears the head of Robert Boyle from a bust of him in the possession of the Society. Two medals may be awarded annually, but in practice bestowals occur at irregular intervals.

New Zealand Institute, Wellington.

Hector Memorial Medal.—Founded in 1912 in honour of Sir James Hector, F.R.S., in association with a Hector Research Fund. The medal is struck in bronze, and bestowed annually in rotation for the following subjects: botany, chemistry, ethnology, geology, physics (including mathematics and astronomy), zoology (including animal physiology). Awarded to that investigator who, working within the Dominion of New Zealand, shall have done most towards the advancement of that (allotted) branch of science. In 1916, Sir Ernest Rutherford received the medal for researches in physics.

Royal Aeronautical Society.

Simms Gold Medal.—Awarded annually for the best paper read in any year before the Society on any science allied to aeronautics, for example, meteorology, wireless telegraphy, instruments. Allotted to a member or non-member.

Taylor Gold Medal.—Awarded annually for the most valuable paper submitted or read during the previous session before the Society. Allotted to a member or non-member.

Sir Charles Wakefield Gold Medal.—Awarded annually to the designer of any invention or apparatus tending towards safety in flying.

Society's Silver Medal.—Awarded at the discretion of the council, for some advance in aeronautical design. Allotted to a member or non-member.

Society's Bronze Medal.—Awarded under the same conditions as those for the silver medal, but for some less important advance in aeronautical design.

Royal Astronomical Society.

Society's Gold Medal.—Instituted in 1823, it was first awarded in 1824 to Babbage in respect of his calculating machine; also to Encke for his determination of the elliptic orbit of Encke's comet. Awarded annually, as may be expedient, for discovery in astronomy or research in the science. The obverse bears the bust of Newton.

Jackson-Gwilt Medal.—Arising from a personal fund established in 1861, the first award came up for allotment in 1897. Struck in bronze, it is bestowed at intervals of not less than three nor more than seven years, and for the promotion of astronomy. The obverse bears the bust of William Herschel.

Institution of Naval Architects.

Institution's Gold Medal.—Awarded annually by the council to any person (not being a member of

that body) who communicates a paper deemed to be of exceptional merit. The gift was established in 1877.

Chemical Society.

Faraday Medal.—Instituted in 1868 in connexion with the establishment of a Faraday lectureship, and usually awarded to foreigners. Struck in bronze, and bestowed at varying intervals. The obverse bears the head of Michael Faraday. The first award was made to Dumas in 1869.

Longstaff Medal.—Instituted in 1881 in connexion with a donation for research work in chemistry, provided by Dr. G. D. Longstaff. Awarded triennially. It is struck in bronze, and the obverse bears a portrait of Longstaff.

Harrison Memorial Prize.—In 1922 the Society established a memorial fund derived from friends and colleagues of Colonel Edward Frank Harrison, Deputy Controller of the Chemical Warfare Department during the War, having for application a triennial prize for the most meritorious and promising original investigations in chemistry by a natural-born British subject of either sex. A bronze medal allotted with the gift reproduces in scale the Society's War Memorial plaque.

Institution of Chemical Engineers.

Osborne Reynolds Medal.—Founded in 1928, the gift of Mr. F. A. Green. Awarded annually for meritorious work accomplished for the advancement of the Institution. The medal is struck in silver.

Moulton Gold Medal.—Founded in 1929. Awarded annually for the best chemical engineering paper of the year "of a mature character", read before the Institution and published in the *Transactions*. Awards may be made to non-members. The obverse bears the head of Lord Moulton.

Society of Chemical Industry.

Society's Gold Medal.—Awarded biennially by the Society for conspicuous services to applied chemistry, by research, discovery, invention, or improvements, or to the Society in the furtherance of its objects. The recipient may be of any nationality, and not necessarily a member. The medal was first presented in 1896.

Messel Memorial Medal.—A gold medal (with an honorarium) is awarded biennially, and commemorates Dr. Rudolph Messel, F.R.S., an original member and benefactor of the Society. The medal is allotted for special distinction in science, literature, or public affairs. The obverse bears the head of Dr. Messel. The first award was made in 1922.

Institute of Chemistry of Great Britain and Ireland.

Meldola Medal.—Founded in 1921, the gift of the Society of Maccabæans. Awarded annually to the chemist "whose published chemical work, issued within the year prior to bestowal, shows the most promise". The recipient must be a British subject not more than thirty years of age at the time of the completion of the work. The medal is struck in bronze: the obverse bears the bust of Raphael Meldola, F.R.S.

Frankland Medal.—Founded in 1927, on the occasion of the jubilee of the Institute, as a memorial to the first president, Sir Edward Frankland, F.R.S. The medal is awarded annually, and is struck in bronze; the obverse bears the bust of Frankland.

Society of Dyers and Colourists, Bradford.

Perkin Gold Medal.—Instituted in 1908 in honour of Sir William Perkin, president in 1907, and awarded at intervals of two or three years for discoveries or work of outstanding importance in connexion with the tinctorial arts. The obverse bears the bust of Perkin, which was modelled by F. W. Pomeroy, R.A.

Dyers' Company's Gold Research Medal.—Instituted in 1908 and awarded annually for a paper submitted to and published by the Society of Dyers and Colourists in the year, embodying the results of scientific research or technical investigations connected with the tinctorial art.

The Society's Medal.—Instituted in 1908, and awarded occasionally in recognition of work of exceptional merit carried out under the Society's Research Scheme. It may be struck either in gold, silver, or bronze.

Manchester Association of Engineers.

Constantine Gold Medal.—First awarded for the year 1903-4, and annually since then. The gift was established by Mr. E. G. Constantine, a past president of the Association, with the object of encouraging papers containing original or other matter conveying the most useful information to the Association upon the practice and theory of engineering. The medal may be allotted to non-members of the Association.

Society of Engineers.

President's Gold Medal.—Awarded annually by the president, through the council, for a paper on a subject of general interest connected with engineering. Instituted in 1886. The obverse bears the Society's seal; the reverse is engraved with particulars of the paper which secured the gift, the names of the author and the president who awarded the medal, with the date.

Institution of Engineers and Shipbuilders in Scotland.

Railway Engineering Gold Medal.—Founded in 1865, and awarded annually for communications in railway engineering and practice.

Marine Engineering Gold Medal.—Instituted in 1865, and awarded annually for communications on subjects in marine engineering.

Institution Gold Medal.—Founded in 1865, and awarded annually for subjects not within the scope of the railway and marine engineering medals.

The obverses of these medals bear the bust of James Watt.

Engineering Institute of Canada.

The Institute awards four medals, named respectively the *Gzowski*, *Kennedy*, *Leonard*, and *Plummer*, each concerned with some aspect of engineering science.

Institution of Civil Engineers.

Telford Gold Medal.—The question of instituting a medal to be awarded for meritorious memoirs was considered in 1827. Thomas Telford, F.R.S., the first president, died in 1834, and through a bequest made by him for the provision of annual premiums, the Institution's Telford medal was bestowed in 1837, and annually since. The award is not limited to papers on any particular subject or subjects. The obverse of the medal bears the head of Telford.

James Watt Gold Medal.—Founded in 1858 and awarded to the author or authors of a paper on any engineering subject, usually one dealing with mechanical engineering. The obverse bears the bust of Watt.

George Stephenson Gold Medal.—Founded in 1881 for award to the author or authors of a paper on any engineering subject. The obverse bears the head of Stephenson.

Kelvin Gold Medal.—In 1913 a memorial window was placed in Westminster Abbey on behalf of the engineers of the British Empire and of the United States of America. A portion of the memorial fund was made available for the founding of a Kelvin gold medal for triennial award for distinction in engineering work or investigation of the character with which Lord Kelvin was especially identified. The first bestowal was made in 1920. The obverse bears the bust of Lord Kelvin.

N.B.—The Institution of Civil Engineers acts as an administrative body, the award of the medal being in the hands of a committee, consisting of the presidents for the time being of eight of the leading engineering institutions in Great Britain, which considers recommendations.

Coopers Hill War Memorial Medal.—Founded in 1921 by the Coopers Hill Society, in memory of its members and relatives of members who fell in the War. In the annual award of the Institution of Civil Engineers, and allotted to the author of the best paper for a selected professional subject. The medal is struck in bronze.

Howard Gold Medal.—Founded in 1927. For quinquennial award to the author of a treatise on any of the uses or properties of iron, or to the inventor of some new and valuable process relating thereto. The first bestowal was made in 1927 as part of the Howard Quinquennial Prize awarded since.

Institution of Electrical Engineers.

Faraday Medal.—Founded in 1921 to commemorate the fiftieth anniversary of the first ordinary meeting of the Society of Telegraph Engineers (now the Institution of Electrical Engineers). Awarded annually, either for notable scientific or industrial achievement in electrical engineering, or for conspicuous service rendered to the advancement of electrical science, without restrictions as regards nationality, domicile, or membership of the Institution. Struck in bronze, the obverse bears the head of Michael Faraday.

Coopers Hill War Memorial Medal.—Founded in 1921 by members of the Royal Indian Engineering College, Coopers Hill, and awarded annually by the Institution of Civil Engineers and triennially in turn by the Institution of Electrical Engineers, the School of Military Engineering, Chatham, and the School of Forestry, Oxford. The medal is struck in bronze.

Willans Gold Medal.—Founded in 1895 by subscription, and awarded triennially alternately by the Institution and the Institution of Mechanical Engineers, for the best paper dealing with the utilisation and transformation of energy, treated especially from the point of view of efficiency or economy. The obverse of the medal bears the head of Peter William Willans. The first award was made in 1897, and by the Institution of Electrical Engineers.

Institution of Gas Engineers.

Birmingham Gold Medal.—Founded in 1881 by funds received from the gas undertakings and companies, gas engineers and managers, and constructors of gas plant in the Birmingham area. It is awarded at the discretion of the council for " Originality in connection with the manufacture and application of gas ", such qualification to be interpreted in its widest possible sense. Allotted at intervals of not less than two years, without distinction of nationality.

H. E. Jones, London, Gold Medal.—Founded in 1905 by the late Mr. H. E. Jones, a past president of the Institution, and bestowed annually. It is awarded for the best contribution dealing with " The principles involved in the construction of works or plant for the manufacture or distribution of gas. . . . The points of good management of a gas undertaking considered in relation to the management of labour, and popularising the use of gas for general purposes, or improvement in carbonising and purifying processes, or in the development of residuals."

Institution Gold Medal.—Awarded at the discretion of the council, at varying intervals, to the author of a paper read at a meeting of the Institution which is considered worthy of such recognition.

Institute of Marine Engineers.

Denny Gold Medal.—Founded in 1891 and offered annually for a paper of merit by a member. The head of the founder, Mr. Peter Denny, appears on the obverse.

Institute's Silver Medal.—Founded in 1922, and is awarded annually for a paper of merit read by a non-member.

Institution of Mechanical Engineers.

Thomas Hawksley Gold Medal.—Founded in 1914, arising from a fund established by Mr. Thomas Hawksley, to perpetuate the memory of Thomas Hawksley, F.R.S., twice president of the Institu-

tion. Awarded annually for the best original paper read at a general meeting of the Institution or printed in the *Proceedings* during the preceding year.

Willans Gold Medal.—Founded in 1895 by subscription and awarded triennially by the Institution and the Institution of Electrical Engineers for the best paper dealing with the utilisation and transformation of energy, treated especially from the point of view of efficiency or economy. The obverse of the medal bears the head of Peter William Willans. The first award was made in 1897, and by the Institution of Electrical Engineers.

Institution of Water Engineers.

Whitaker Medal.—Founded in 1927, through a fund placed at the disposal of the Institution by a member (desiring to remain anonymous), the interest on which to be used for a bronze medal to be given annually to the author of the best paper each year dealing with the application of geology to water engineering. The donor intended that the gift should be not only a stimulus and encouragement to research, but should also tend to memorialise the late William Whitaker, F.R.S., the eminent geologist. The obverse bears the head of Whitaker, from the rendering of Mr. Frank Bowcher. The first award was made in 1930 for a paper by Mr. R. C. S. Walters on "The Hydrogeology of the Chalk of England".

Institute of British Foundrymen.

Oliver Stubbs Gold Medal.—Established in 1921 by the National Ironfounding Employers' Federation and presented to the Institute to encourage and reward efforts made by its members to impart knowledge on the practice and theory of founding. Awarded annually. The obverse bears the head of Oliver Stubbs.

Iron and Steel Institute.

Bessemer Gold Medal.—Founded in 1873 by Mr. (afterwards Sir Henry) Bessemer, and awarded annually for distinguished merit in promoting the metallurgy of iron and steel.

Andrew Carnegie Gold Medal.—Founded in 1901 by Mr. Carnegie. It is awarded to the author of the paper considered to be the most meritorious of those presented in any one year. The award of this medal remained in abeyance during the War, and for some years afterwards; in 1927 the reports of research work submitted within the previous thirteen years were considered, and three awards were made. Since 1927 no further award has been made. The obverse of the medal bears the bust of Andrew Carnegie.

Gold Medal of the Blacksmiths' Company, City of London.—An offer by the Court to award annually a gold medal bearing the arms of the Company was accepted in 1919. It was agreed that the council of the Iron and Steel Institute should recommend every year the name of a member for the award, preference being given (other things being equal) to members who were or had been students or apprentices practically engaged in the working or the manufacturing of iron or steel, or had achieved work of merit or importance in connexion with the manufacture of iron and steel. The first award was made in 1920.

London Mathematical Society.

De Morgan Gold Medal.—Following the death of Prof. A. De Morgan, in 1871, it was decided to establish a medal in trust for the advancement of mathematical science, and as a memorial of the Society's first president. The gift is of triennial allocation, open to mathematicians of all countries, and is not restricted to any particular branch of mathematical study. The die was entrusted to Thomas Woolner, R.A., and the bust of De Morgan appears on the obverse of the medal. The first award was made in 1884 to Prof. A. Cayley.

Royal Meteorological Society.

Symons Gold Medal.—Founded in 1901, and awarded biennially for distinguished work done in connexion with meteorological science, irrespective of sex or nationality. The obverse of this memorial medal bears the head of G. J. Symons, F.R.S., founder of the British Rainfall Organization.

Institution of Mining and Metallurgy.

Institution Gold Medal.—Founded in 1902, and awarded annually for conspicuous services in the advancement of the science and practice of mining or metallurgy.

Canadian Institute of Mining and Metallurgy.

Leonard Gold Medal.—Awarded annually, through a fund established by Lieut.-Col. R. W. Leonard, for the best paper on a mining subject, communicated either to the Engineering Institute of Canada or to the Canadian Institute, and open to all classes of members of either body.

Randolph Bruce Gold Medal.—An annual award for the most notable contribution in the field of practical mining, metallurgy, or geology, to the advance of the mining industry of Canada. Provision has been made (1929) by His Honour R. Randolph Bruce, Lieutenant-Governor of British Columbia, for the successive award to members of the Institute of ten gold medals.

North of England Institute of Mining and Mechanical Engineers, Newcastle-on-Tyne.

Greenwell Medal.—Awarded either in gold, silver, or bronze, at the option of the council of the Institute, to the writer of a paper recording the results of experience of interest in mining, and especially where deductions and practical suggestions are made by the writer for the avoidance of accidents in mines. The medal is provided out of a fund of £100 given by the late Mr. G. C. Greenwell in 1900. The head of the donor appears on the obverse of the medal.

Institution of Petroleum Technologists.

Boverton Redwood Medal.—In 1921, Mr. A. Duckham expressed a wish to establish such gift

to commemorate the late Sir Boverton Redwood, founder of the Institution, and its first president. The award is biennial, and for a paper or papers deemed to advance knowledge of the technology of petroleum. The council decided in 1924 that in the first instance papers should be considered from so far back as 1919, the year following the War. Accordingly the first award, as for 1919–21, was made to M. Paul Chambrier, who described the revised method of working the petroleum deposits at Pechelbronn, Alsace. The medal is struck in bronze, and allotted irrespective of nationality. The head of Redwood appears on the obverse.

Manchester Literary and Philosophical Society.

Dalton Medal.—Founded in 1864, but the first award was not made until 1898, the medal being adopted "for presentation on such occasions as the Society may determine". The last recipient (1919) was Sir Ernest Rutherford. The obverse bears the head of John Dalton. The medal is struck in bronze.

Royal Philosophical Society of Glasgow.

Graham Gold Medal.—Founded in 1878. Candidates for the award are required to enter a paper giving an account of an unpublished original research in any branch of chemical science, pure or applied. The medal is allotted for the particular research considered of the highest merit and most likely to aid in the advancement of chemical science. The award may take the form, as desired, of (1) the medal in gold; (2) the medal in bronze and scientific instruments or books; (3) the medal in bronze and the balance of the fund for application in chemical research. The obverse of the medal bears the bust of Thomas Graham, with the date of his birth and death. (This medal has not been allotted for some years. The original fund provided also for special lectures in chemistry, and the whole income is now made available mainly for the purpose of the "Graham Lectures".)

Royal Photographic Society of Great Britain.

Exhibition Medal.—First awarded in 1877, twenty-four years after the Society's Exhibition was inaugurated. The medal is struck in bronze. The obverse bears the head of H.R.H. the Prince Consort.

Progress Medal.—Founded in 1878. Awarded in recognition of any invention, research, publication, or exhibition which, in the opinion of the council, shall have resulted in any important advance in the development of photography. The medal is struck in silver.

John Traill Taylor Memorial Medal.—Instituted in 1898, and struck in bronze, the medal is bestowed in association with a memorial lecture. The obverse bears the bust of Taylor.

Hunter and Driffield Memorial Medal.—Instituted in 1920, and struck in silver, the medal is bestowed in association with a memorial lecture.

Physical Society of London.

Duddell Medal.—Founded in 1922 as a memorial of William Duddell, F.R.S., and awarded annually, irrespective of nationality and sex, for contributions to the advancement of knowledge by the invention or design of scientific instruments, or by the discovery of material used in their construction. The medal is struck in bronze; the obverse bears the bust of Duddell.

Institution of the Rubber Industry.

Colwyn Gold Medal.—Established through a gift made by Lord Colwyn, and first awarded in 1928. It is allotted annually for conspicuous services of a scientific or technical character, bearing on the improvement or development of rubber manufacture or production. The recipient must be a British subject. The obverse of the medal bears the bust of Lord Colwyn.

Royal Statistical Society.

Howard Medal.—Instituted in 1873, and bestowed upon the author of an essay on some branch of social statistics, selected by the council. The medal is struck in bronze, and competition is not limited to fellows of the Society. The obverse bears the bust of John Howard, F.R.S.

Guy Medal.—Instituted in 1891 in honour of Dr. William A. Guy, F.R.S. Awards are confined to fellows of the Society, and to those who are adjudged to merit distinction on account of original contributions to the theory or practical applications of statistics. The medal may be of gold, silver, or bronze. The obverse bears the bust of Guy.

III. Biological Sciences (including Geology and Geography).

Royal Society of London.

Darwin Medal.—Arising from the transfer in 1885 of an International Darwin Memorial Fund, a silver medal is awarded biennially in recognition of work of acknowledged distinction (especially in biology) in the field in which Charles Darwin himself laboured. The obverse bears the bust of Darwin. Bestowal may be made without distinction of nationality or sex. First awarded in 1890.

Buchanan Gold Medal.—Awarded quinquennially in respect of distinguished services to hygienic science or practice in the direction either of original research or of professional, administrative, or constructive work. Bestowal may be made without distinction of nationality or sex. First awarded in 1897. The obverse bears the head of Sir George Buchanan, F.R.S.

See also General and Physical and Mathematical Sciences sections.

Asiatic Society of Bengal.

Barclay Memorial Medal.—Awarded biennially for conspicuously important contributions to medical

or biological science with reference to India. The next award falls due in 1931.

Annandale Memorial Medal.—Awarded triennially for important contributions to the study of anthropology in Asia. The next award falls due in 1931.

Joy Gobind Law Memorial Medal.—Founded in 1929 by Dr. Satya Churn Law, and for triennial award for conspicuously important work on zoology in Asia. The first award was made in February 1930.

Paul Brühl Memorial Medal.—Instituted in 1929 through funds provided by the "Brühl Farewell Committee". To be bestowed triennially for meritorious researches in Indian botany, in commemoration of the life-work of Prof. Paul J. Brühl, a teacher of botany in India, chiefly in Calcutta. The first award will be made in 1932.

See also General section.

Australian Association for the Advancement of Science.

Mueller Memorial Medal.—In 1902 the Association accepted a fund in the hands of the Mueller National Memorial Committee with the view of founding a medal in memory of Baron Sir Ferdinand von Mueller, long identified with research work in natural science in Australia. The interest of the fund is allocated for a bronze medal, awarded biennially to the author of important contributions to anthropological, botanical, geological, or zoological science, published originally within His Majesty's dominions, preference being always given to work having special reference to Australasia. A money gift may be allotted with the medal. Rectangular in shape, the obverse bears a quarter-length presentment of von Mueller.

Royal Society of Edinburgh.

Neill Gold Medal.—Instituted in 1851, and awarded biennially or triennially, together with a sum of money from the fund, for a paper of distinguished merit on a subject of natural history, by a Scottish naturalist, presented to the Society during the period; or it may be awarded for a work or publication by some distinguished Scottish naturalist in some branch of natural history, bearing date within five years of the time of award. The obverse of the medal bears the head of Patrick Neill, LL.D.

Bruce Medal.—Instituted in 1923 to commemorate the work of Dr. W. S. Bruce as an explorer and scientific investigator in polar regions. Open to workers of all nationalities, with a preference for those of Scottish birth or origin. Awarded biennially, in bronze, with a sum of money, for some notable contribution to the natural sciences; to be in the nature of new knowledge, the outcome of a personal visit to polar regions on the part of the recipient. The Royal Physical Society, Edinburgh, and the Royal Scottish Geographical Society assist in the allotment.

See also General section.

Royal Society of New South Wales, Sydney.

Clarke Medal.—The Society was inaugurated in 1867 by the Rev. W. Branwhite Clarke (F.R.S., 1876). On his death in 1878 a medal in his honour was founded, which is awarded annually for researches in natural science, and struck in bronze. The obverse bears the bust of Clarke.

New Zealand Institute, Wellington.

Hutton Memorial Medal.—Founded in 1909 in honour of Capt. Frederick Wollaston Hutton, F.R.S., in association with a Hutton Research Fund. The medal is struck in bronze, and bestowed not oftener than once in every three years upon persons who have made "some noticeable contribution" in connexion with the zoology, botany, or geology of New Zealand. The awards are made only to those who have received the greater part of their education in New Zealand, or who have resided in New Zealand for not less than ten years.

Royal Society of Tasmania.

Johnston Memorial Medal.—In association with a lecture, this medal, struck in bronze, was established by public subscription to commemorate Mr. R. M. Johnston, a pioneer geologist (deceased 1918), author of "The Geology of Tasmania". Awarded at intervals, the first recipient (1923) was Sir T. Edgeworth David, F.R.S. The obverse bears the bust of Johnston.

Royal Anthropological Institute.

Huxley Memorial Medal.—Awarded annually in association with a memorial lecture given by some distinguished anthropologist, either British or foreign. The medal is struck in bronze; the obverse bears the bust of Thomas Henry Huxley.

Rivers Memorial Medal.—Founded in 1923, and awarded for specially meritorious field work in physical or cultural anthropology, preference being given to the claims of British subjects or fellows of the Institute. The medal is struck in bronze; the obverse bears the bust of Dr. W. H. R. Rivers, F.R.S.

British School of Archæology in Egypt.

Petrie Memorial Medal.—Founded in 1923, and awarded every five years for archæological work by English-speaking workers. The obverse bears the bust of Sir Flinders Petrie, F.R.S., long concerned in exploration and research in Egyptian archæology. The medal is struck in bronze.

Society of Apothecaries of London.

Society's Gold Medal.—Instituted in 1925, and awarded, usually annually, for services rendered to the science of therapeutics. The obverse bears the effigy of Galen, by T. H. Paget, after William Wyon, R.A.

Royal Botanical Society of London.

Society's Gold Medal.—Founded in 1840, and awarded for excellence in applied botany or flori-

culture. The Society was incorporated in 1839 for the promotion of botany and its application to manufactures, medicine, and the arts. Silver and bronze medals are also bestowed.

Institute of Brewing.

Horace Brown Gold Medal.—Founded in 1925 and awarded triennially for eminent services on the scientific or technical side of the fermentation industries, there being no disqualification in respect of nationality or sex in bestowal. The obverse of this memorial medal bears a replica of a crayon portrait of H. T. Brown, F.R.S., by Sargent.

Chadwick Trust.

Chadwick Gold Medal.—Founded under the testament of Sir Edwin Chadwick, K.C.B., in association with a prize, and awarded to such officer of the medical services of the Army, Navy, or Air Force as shall during the preceding five years have specially assisted in promoting the health of the men of the force to which he is attached through medical and sanitary work, or other scientific researches.

Royal Geographical Society.

Founder's Gold Medal.—At the foundation of the Society in 1830, its Royal Patron, King William IV., granted an annual premium of fifty guineas for the encouragement and promotion of geographical science and discovery. The fifth recipient received it in the form of a gold medal, and awards have been from that date, though not invariably, medallic. On the accession of Queen Victoria, the annual grant was continued, and it was resolved that for the future two gold medals should be awarded in each year: (*a*) the Founder's medal, to bear on the obverse the portrait of the founder; (*b*) the Patron's medal, to bear the portrait of the reigning sovereign. The two medals are equal in value and in honour.

Patron's Gold Medal.—(See above.)

Victoria Medal.—On the death of Queen Victoria in 1901, the council instituted the Victoria Medal, to be awarded from time to time for conspicuous merit in scientific research in geography. The medal bears on the obverse the portrait of the Queen (as in youth).

Royal Scottish Geographical Society.

Society's Gold Medal.—Instituted in 1890, and conferred by the council on distinguished geographers and travellers, irrespective of nationality, in consideration of special services to geographical science. Awarded at suitable periods, as also silver and bronze replicas in the same type.

Livingstone Gold Medal.—Instituted in 1901 by Mrs. A. L. Bruce in memory of her father, Dr. Livingstone. Awarded annually, irrespective of nationality, for distinguished service to geographical exploration or research. The obverse of the medal bears the bust of David Livingstone.

Bruce Medal.—See Royal Society of Edinburgh, Biological Sciences section.

Geological Society of London.

Wollaston Gold Medal.—First awarded in 1831, and established through the will (1828) of Dr. William Hyde Wollaston, F.R.S. The obverse bears the bust of Wollaston. The medal is bestowed annually.

Murchison Medal.—Founded in 1871, under the conditions of a geological fund established through the will of Sir Roderick I. Murchison, Bart., F.R.S. Awarded annually in bronze. The obverse bears the bust of Murchison.

Lyell Medal.—Founded in 1873 through the will (1875) of Sir Charles Lyell, Bart., F.R.S., and first awarded in 1876. The obverse of the medal, which is struck in bronze, bears the head of Lyell. It is bestowed annually without restriction of country or sex.

Bigsby Gold Medal.—Founded in 1876 by Dr. John J. Bigsby, F.R.S. Awarded biennially, without restriction of country. The obverse bears the bust of Bigsby.

Prestwich Gold Medal.—Founded in 1896 through the will of Sir Joseph Prestwich, F.R.S. Awarded triennially without restriction of country or sex. The obverse bears the bust of Prestwich.

Royal Horticultural Society.

The Society was founded in 1804; it aims at spreading a knowledge of the science of horticulture. Various medals applicable to different branches of the science are awarded. We select those associated with the early history of the Society, and of historic interest.

Banksian Medal.—Instituted in 1820 in commemoration of Sir Joseph Banks, F.R.S., one of the founders of the Society. Struck in bronze, silver, and silver-gilt; the obverse bears the head of Banks.

Knightian Medal.—Instituted in 1836 in commemoration of Thomas Andrew Knight, F.R.S., president 1811-38. Struck in bronze, silver, and silver-gilt; the obverse bears the head of Knight.

Lindley Medal.—Instituted in 1866 in commemoration of Dr. John Lindley, F.R.S., sometime secretary. Struck in bronze, silver, and silver-gilt; the obverse bears the head of Lindley.

Victoria Gold Medal of Honour.—Instituted in 1897 in commemoration of the sixtieth year of reign of Queen Victoria, and awarded to British horticulturists selected as deserving of special honour at the hands of the Society.

Linnean Society of London.

Linnean Gold Medal.—Founded in 1888, and awarded annually to a biologist of eminence, usually to a botanist and zoologist in alternate years. The obverse bears the bust of Linnæus.

Trail Medal.—Founded in 1910 in association with a fund established by Prof. J. W. H. Trail, F.R.S., "to encourage study that throws light upon the substance known as protoplasm, or the physical basis of life". The medal is struck in bronze and bestowed at intervals of not less than five years. The obverse bears the bust of Linnæus.

Crisp Medal.—Founded in 1912 and awarded in

association with a fund established by Sir Frank Crisp, Bart., in recognition of the best paper dealing with microscopical research by a fellow and published by the Society since the previous award. The medal is struck in bronze and bestowed at intervals of not less than five years. The obverse bears the bust of Linnæus.

Medical Society of London.

Fothergill Gold Medal.—Awarded triennially for significant advances in medical science. The Fothergillian medal was first awarded in 1787; in 1803 it was awarded to Edward Jenner. From 1893 the administration of the trust has been in conformity with a scheme of the Charity Commissioners. The most recent award (1929) was to Sir Thomas Lewis, F.R.S. The obverse of the medal bears the bust of Anthony Fothergill, M.D.

Royal Society of Medicine.

Society's Gold Medal.—Awarded triennially to a man of science (or a woman) who has made valuable contributions to the science and art of medicine. Established in 1920 through funds provided by the late Dr. R. Murray Leslie.

Jenner Memorial Medal.—Founded in 1896 by the Epidemiological Society (now merged in the above society) "in recognition of the greatest medical service ever done to man". Awarded, struck in bronze, for services in the prevention and control of epidemic disease. The obverse bears the bust of Jenner.

British Medical Association.

Association Gold Medal.—Founded in 1877 and bestowed annually "For Distinguished Merit". Awards are made to those who shall have conspicuously raised the character of the medical profession by scientific work, by extraordinary professional services, or by special services rendered to the Association.

British Medical Association, Australia Branch.

Association Gold Medal.—The Federal Committee in Australia instituted a medal in 1924 for distinguished service, and for the purpose of "perpetuating the appreciation of the Federal Committee of signal services rendered by members of the British Medical Association in Australia".

British Medical Association, South Africa Branch.

The institution of a medal has been decided on; regulations for award are under consideration.

Liverpool School of Tropical Medicine.

Mary Kingsley Medal.—Commemorates the work of Mary Kingsley in West Africa, and bestowed in recognition of distinguished scientific achievement. There is no restriction as to nationality in the award. The medal is struck in bronze, and the obverse bears the bust of Miss Kingsley.

Pharmaceutical Society of Great Britain.

Hanbury Memorial Gold Medal.—Founded in 1875, and awarded biennially for "high excellence in the prosecution or promotion of original research in the chemistry and natural history of drugs". The medal commemorates Daniel Bell Hanbury, remembered for his researches in materia medica; the obverse bears his head.

Harrison Lectureship Medal.—Founded in 1921, and associated with a biennial lecture on a subject relating to the science and practice of pharmacy. The medal, struck in silver, commemorates Lieut.-Col. E. F. Harrison, deputy controller of the Chemical Warfare Department during the War. The obverse bears the head of Harrison.

The Society also bestows annually the silver Pereira Medal, as the result of examination, to a pharmaceutical chemist. The medal (founded in 1860) commemorates Jonathan Pereira, the classic teacher of materia medica.

Royal College of Physicians, London.

Baly Gold Medal.—Founded in 1866, arising from a trust fund established by Dr. F. D. Dyster, "in memoriam Gulielmi Baly, M.D.". Awarded biennially to the person who shall be deemed to have most distinguished himself in the science of physiology, especially during the two years immediately preceding, and is not restricted to British subjects. The obverse bears the bust of Baly.

Moxon Gold Medal.—Founded in 1886 through a trust fund established as a memorial of Dr. Walter Moxon. Awarded triennially to the person who is deemed to have most distinguished himself by observation and research in clinical medicine. Bestowal is not restricted to British subjects. The obverse bears the bust of Moxon.

Weber-Parkes Medal and Prize.—Provision is made under the terms of a trust established in 1895 by Dr. (afterwards Sir) Hermann Weber in memory of Dr. E. A. Parkes, for a prize of one hundred and fifty guineas, accompanied by a silver medal. The subject scheme of the prize relates to tuberculosis. The allotment is triennial, and is not restricted in nationality. The obverse bears the bust of Weber.

Bisset Hawkins Gold Medal.—Instituted in 1896 as a memorial to Dr. Francis Bisset Hawkins, and bestowed triennially on some duly qualified medical practitioner, who is a British subject, and has, during the preceding ten years, specially advanced sanitary science or promoted public health. The obverse bears the bust of Bisset Hawkins.

Royal Sanitary Institute.

Rogers Field Medal.—Founded in 1901, and awarded in silver for the first time in 1903. It commemorates the work of Mr. Rogers Field, a pioneer of sanitation, and is bestowed in connexion with the annual congress of the Institute for an exhibit of special merit from a hygienic point of view. The obverse bears the head of Field.

Royal College of Surgeons of England.

Honorary (Gold) Medal.—Instituted in 1802, and bestowed at varying intervals. In awarding, the leading considerations are liberal acts or distinguished labours, researches, and discoveries,

eminently conducive to the improvement of natural knowledge and of the healing art.

John Hunter Medal and *Triennial Prize.*—The medal itself, executed in bronze, was founded in 1867, and is allocated with the (older) triennial prize. From 1925 the terms of this joint gift provide for award to some fellow or member of the College who has, during the preceding ten years, done such work in anatomy, physiology, histology, embryology, or pathological anatomy, as deserves special recognition. The obverse bears the bust of Hunter.

Lister Medal.—In 1920 the College became trustees of the Lister Memorial Fund, and the following provision is in operation: That out of the General Fund a sum of £500, together with a bronze medal, be awarded every three years, irrespective of nationality, in recognition of distinguished contributions to surgical science, the recipient being required to give a lecture in London under the auspices of the College. The obverse of the medal bears the head of Lord Lister.

Cartwright Medal.—Awarded quinquennially in bronze, with an honorarium, to the author of the best essay upon a subject relating to dental surgery, and selected by the council upon the recommendation of a committee. The medal was bestowed for the first time in 1911, and bears on the obverse the head of Samuel Cartwright, F.R.C.S.

Royal College of Surgeons of Edinburgh.

Caird Medal.—Founded in 1927, in association with a money gift, as a memorial to Francis Mitchell Caird, Regius professor of clinical surgery, University of Edinburgh, 1908-1919. It is to be awarded triennially in bronze for an essay on a subject in surgery or surgical pathology, based on personal observation and research, and open to graduates of Edinburgh and to licentiates and fellows of the Royal College of Surgeons who have studied in Edinburgh for a period of at least two years, and have been qualified as practitioners for not more than seven years. The precise design of the medal has not yet been settled, but an award under the scheme will be made shortly.

Royal College of Veterinary Surgeons.

Steel Memorial Medal.—Instituted in 1891 in memory of John Henry Steel, Army Veterinary Department, principal of the Bombay Veterinary College, and awarded by the council triennially as a reward for scientific or literary work of merit connected with the veterinary profession. The medal is struck in silver, and fellows and members of the College are alone eligible. The obverse bears the head of Steel.

Zoological Society of London.

Society's Medal.—In 1837 the council decided to "offer six medals annually, by way of premiums, for subjects connected with zoology". In 1847 two medals (the first), struck in silver, were awarded, in 1859 nine. "Silver medals have continued to be awarded at irregular intervals, and for very different reasons, and it may be an important duty of the Council at some future time to revert more to the original intention of the Society and present medals annually for specific contributions to zoology, in the form of the introduction of very rare animals, or for direct contribution to knowledge" ("Centenary History of the Zoological Society of London", 1929). The Society's medal struck in bronze has usually been given to keepers for special services.

Royal Zoological Society of Ireland.

Animal Photography Medals.—The council allots a silver and bronze medal respectively for sets of photographs taken in its gardens by amateurs.

Royal Geological Society of Cornwall.

Bolitho Gold Medal.—Instituted under the will (1895) of Mr. William Bolitho, and awarded annually for such member whose attainments, labour, and discoveries in geology or mineralogy shall best deserve recognition. This, the senior scientific society of Cornwall, was founded in 1814. The first bestowal of the medal (1896) was made to Prof. R. Etheridge, F.R.S.

Royal Institution of Cornwall.

Henwood Gold Medal.—Awarded triennially for the best treatise or paper in the subjects of geology, mineralogy, mining operations, botany, ornithology, ichthyology, conchology, or antiquities of Cornwall. The gift arises under the will of William Jory Henwood, F.R.S., who died in 1875. Bestowal is not confined to members. The obverse bears the head of Henwood.

Printed in Great Britain by R. & R. Clark, Limited, Edinburgh.

Obituary.

DR. W. M. W. HAFFKINE.

THE death of Waldemar Haffkine on Oct. 26 last will recall an era in bacteriology of which few of the active participators still survive.

The discovery in 1880 by Pasteur, that fowl cholera can be prevented by the inoculation of living attenuated cultures, and his success with this disease, as also with swine erysipelas, anthrax, and hydrophobia, seemed to open up a field of endless possibilities. One of the early workers to transfer this activity to human beings was Haffkine, who was enabled to go to India and inoculate vast numbers of people against Asiatic cholera and bubonic plague. Following the Pasteurian tradition, he first used living cultures, as Ferran y Clua (1852–1929) had done before him in Spain. The results were not satisfactory; and later, Haffkine turned to the use of killed cultures, the value of which had previously been shown (1884–1886) by D. E. Salmon and Theobald Smith in America in the case of prophylactic inoculation against hog cholera.

Waldemar Mordecai Wolff Haffkine was born in Odessa on Mar. 16 (3), 1860, the son of Aaron Haffkine. He received a classical education at Berdiansk (South Russia) and studied science in the University of Odessa (1879–83). He afterwards worked at the Zoological Museum in Odessa (1883–88) and then came west as assistant professor of physiology in the Medical School of Geneva. Ultimately, he made his way to Paris in the wake of Metchnikoff, met Pasteur, and was appointed (1889) *préparateur* at the Pasteur Institute, which had been inaugurated the previous year. He remained in this post until 1893, when he went to India full of ideas of stamping out cholera by prophylactic inoculation. Here he found a great field for his efforts and in the midst of his work he turned aside to combat another scourge—bubonic plague—which was beginning to get a firm hold of Bombay. Under his directions vast quantities of the protective vaccines were made and inoculated on a wholesale scale. In the course of his labours he received great publicity and fame, partly on account of the enthusiasm of his personality and partly on account of the uncritical attitude towards some of his results.

Haffkine was regarded as a kind of second Jenner, but when a study of his plague results was made by the English Plague Commission in India, the report was, on the whole, adverse to his claims. None the less, he was regarded as a bacteriological wizard. He retired from the India service in 1915 and returned to Europe, where he lived for a time in Paris and afterwards at Boulogne-sur-Seine. He wrote relatively little of a scientific character in bacteriology. W. B.

WE regret to announce the following deaths:

Dr. J. V. Elsden, joint editor of the *Colliery Guardian* and author or part author of several well-known geological works, and treasurer from 1916 until 1921 of the Geological Society of London, aged seventy-four years.

Mr. C. J. B. Macdonald, an honorary life governor of the Royal Agricultural Society of England and editor since 1927 of the Society's *Journal*, on Nov. 10, aged sixty-six years.

Prof. E. R. Matthews, chief drainage engineer to H.M. Office of Works, and formerly Chadwick professor of municipal engineering in the University of London, on Nov. 6, aged fifty-seven years.

News and Views.

HIS Majesty the King has approved of the following awards this year by the president and council of the Royal Society in respect of the two Royal Medals: Royal Medal to Prof. O. W. Richardson, for his work on thermionics and spectroscopy; Royal Medal to Prof. J. E. Marr, for his pioneer work in the accurate zoning of the palæozoic rocks. The following awards of medals have also been made by the president and council: Copley Medal to Sir William Bragg, for his distinguished contributions to crystallography and radioactivity; Rumford Medal to Prof. Peter Debye, of Leipzig, for his work relating to specific heats and X-ray spectroscopy; Davy Medal to Prof. R. Robinson, for his work on the constitution and synthesis of natural products, and for his contributions to the theory of organic reactions; Darwin Medal to Prof. Johannes Schmidt, of Copenhagen, for his work on extended oceanographical expeditions, and for his genetic studies in animals and plants; Hughes Medal to Sir Venkata Raman, of Calcutta, for his studies on the abnormal scattering of light.

THE following is a list of those recommended by the president and council for election to the council of the Royal Society at the anniversary meeting on Dec. 1: *President*: Sir F. Gowland Hopkins; *Treasurer*: Sir Henry Lyons; *Secretaries*: Dr. H. H. Dale and Dr. F. E. Smith; *Foreign Secretary*: Lord Rayleigh; *Other Members of Council*: Prof. E. V. Appleton, Prof. G. Barger, Prof. A. E. Boycott, Prof. E. P. Cathcart, Sir Alfred Ewing, Prof. E. S. Goodrich, Prof. G. H. Hardy, Sir Harold Hartley, Sir Thomas Lewis, Dr. W. H. Mills, Prof. E. A. Milne, Dr. A. B. Rendle, Prof. R. V. Southwell, Prof. G. I. Taylor, Prof. D. M. S. Watson, and Prof. W. W. Watts.

SIR ARTHUR KEITH was elected Rector of the University of Aberdeen on Nov. 8 in succession to the late Lord Birkenhead. Sir Arthur, who was a non-political candidate, was opposed by Col. John Buchan, M.P. (Unionist), and obtained a majority of votes in each of the 'nations', Mar, Buchan, Angus, and Moray, the total numbers being 310 as against 231. Although not unprecedented, the election of a non-political candidate is rare. Sir Arthur was formerly a student of Aberdeen and as one of the most distinguished of its *alumni* now living had a strong claim on the suffrages of the members of his University. His studies in the comparative morphology of the Simiidæ—in particular of the anthropoids—and

of early types of man have served to support as well as to elucidate the Darwinian hypothesis of the descent of man. His gift of lucid and graceful exposition has won him an unrivalled place as a public lecturer, as is testified by the fact that he has held all the lectureships open to members of the medical profession. By his more popular writings and lectures he has done much to stimulate the interest of the general public in the problems of anthropological science. In his official capacity as Curator and then Director of the Royal College of Surgeons, he has indeed deserved well of the members of the medical profession. Among the many positions of honour to which he has been called, it will suffice to mention the presidential chair of the Anatomical Society, of the Royal Anthropological Institute, and of the British Association at its Leeds meeting in 1927. We offer Sir Arthur our congratulations on this latest and perhaps most welcome of his honours.

THE pamphlet "How to Tackle Unemployment", published last week by the Liberal party, contains no strikingly new ideas. The policy advocated by its authors, Mr. Lloyd George, Lord Lothian, and Mr. Seebohm Rowntree, differs little from that outlined in "Labour and the Nation", which has been the inspiration of the Labour party for the past three years. Neither the analysis of the causes of the present world-depression and the decline of British basic industries, nor the suggested remedies for unemployment, bears the stamp of originality. It is indeed unlikely that the Labour Government's Economic Advisory Council, among the members of which are Sir Daniel Hall, Mr. J. M. Keynes, and Mr. G. D. H. Cole, had not already reached much the same conclusions as to causes and submitted similar remedial schemes in even more detail than those put forward in the pamphlet. Nevertheless, the task of industrial reconstruction will undoubtedly be made easier by the publication of the Liberal leaders' selective synthesis, not the least noteworthy part of which is the recognition given to the part which scientific and technical knowledge should play in the future development of the British Empire.

THE Liberal pamphlet contrasts the position of the scientific and technical experts in Germany with their position in Great Britain. In Germany the Credit Banks are equipped with expert staffs "capable of investigating both the efficiency of going concerns and the soundness of proposed industrial ventures", and in consequence even small concerns have often been enabled to raise necessary capital from the public. In Great Britain the "bankers are masters but have so far not felt it proper to accept responsibility for enforcing reorganisation or greater efficiency" in industry, largely due to the fact that they have not appropriate experts on their staffs or scientific or technical experts on their boards of directors. The pamphlet also deals with the important part which science has to play in the development of those parts of the world where the standard of living is very low, and particularly of the British Colonial Empire. The proper investment of capital would enable agriculture, the basic industry of our colonies, to be developed scientifically and inevitably raise the standards of life of the backward races; this, over a period of time, would play an extremely important part in the solution of the unemployment problem. Both at home and overseas "enterprise . . . will increasingly take the form of the exploitation of new scientific development and new inventions". It is not suggested that it is the business of governments to be responsible for invention, but it is asserted that governments should assist in every way to create the conditions whereby the pursuit of industrial research and the discovering and wise application of invention are encouraged to the utmost.

IN a pamphlet entitled "The Agricultural Crisis and the Way Out" (Messrs. Jarrold and Sons, Ltd., Norwich, 3*d*.), Dr. Cloudesley Brereton points out that agriculture is still the basic industry of Great Britain and still employs the largest number of hands, though a million acres have gone out of cultivation and 100,000 agriculturists have left the land. Since 1922, the great majority of farmers have been losing money year by year and there has been a progressive drop in the prices of wheat, barley, and oats. Prices, indeed, for most kinds of agricultural products are unnaturally low, according to Dr. Brereton, partly because farmers have not organised their marketing and partly because of the unrestricted competition of foreign produce. Traders in meat, bread, and vegetables have become highly organised as a result of the impetus given by War-time organisation for the distribution of food, and they have been able to force a lower price on the producer and to raise prices against the consumer. They have ceased to interest themselves in helping the farmer to get rid of any surplus during a glut, preferring to buy a more or less fixed amount, regardless of the supply available, and to retail it at more or less fixed prices according to the season. Dr. Brereton looks for a solution of the agricultural problem in the development of some form of organised marketing, though he holds that until this is developed nothing but a guaranteed price for wheat, with a duty on foreign malting barley and the prevention of 'dumping', can tide the farmer over the interval. The cost to the Government would gradually decrease as marketing schemes were developed. The German plan of compelling all millers to grind a fixed quota of home-grown wheat might also be adopted.

A USEFUL pamphlet by P. Good describing the organisation of the electrical industry in Great Britain has just been published by the Institution of Electrical Engineers. About sixty organisations are described, beginning with the Institution of Electrical Engineers and finishing with the British National Committee of the World Power Conference. The Electrical Research Association (E.R.A.) co-operates with those responsible for the laboratories in the universities, technical colleges, and schools throughout the country. This forms a valuable link between the colleges and industry. The value of the work done by this Association is known to be far in

excess of the expenditure incurred. The research carried out on overhead transmission lines at a comparatively trifling cost has been shown to represent a saving of 10 per cent on the three million pounds per annum expended on constructing these lines. The Electricity Commissioners Department also, which has been entrusted with supervising the supply of electricity throughout Great Britain, has done an immense amount of work. The country has been divided into eight areas, and very complete statistics regarding the number and nature of the undertakings in these districts have been collected. The Commissioners have paved the way for the centralisation of the supply, which is at present proceeding rapidly. The Institute of Transport is linked up with the electrical industry owing to the many important developments in the application of industry to transport which have recently taken place. It is a little disappointing to read that the total route mileage electrified in England is only 615·8, of which 307·7 miles, or nearly half, has been done by the Southern Railway.

"HEREDITY and Predestination" was the subject of the Lloyd Roberts Lecture delivered by Dr. Barnes, the Bishop of Birmingham, at Manchester Royal Infirmary on Nov. 7. It is an effort to mould upon some of the biological theories of the day an interpretation of the relationship of man to God, or, perhaps more accurately, it may be said to be an attempt to support certain widely held beliefs by particular appeal to the notion of genes as the repositories of unit characters. The general progress of the inorganic and organic worlds, culminating in civilised man, leads Dr. Barnes to a belief in the purpose and intelligent will of God. He does not believe in the inheritance of acquired characters, nor will he risk being called a vitalist, but he is a thorough-going believer in the gene. "Tennyson's words, 'Man is man and master of his fate', must be altered to 'The genes are genes and masters of man's fate'." Now changes in the genes appear to be the raw material of evolution, and through them the creative process works; that is to say, if ethical theism be accepted, that in modifications of the genes the activity of God is expressed. Yet modifications of the genes, expressed in visible mutations, seem to be devoid of any ethical character whatever, so that, as Dr. Barnes sees the matter, good and evil arise with equal frequency in the variations associated with heredity, but the Divinely guided creative process of which we are products is active through the environment. The determinism which is implied in inheritance does not necessarily mean that we have no freedom of choice.

DR. BARNES goes on to say that "the notion that evil is due to a fall, to some act of spiritual rebellion against God, must be abandoned", since we have learned that evil and good are equally likely to arise at every stage of the evolutionary process. The 'evil and good' of his argument are simply adjustment or maladjustment to environment: the good are the survivors, the evil the individuals smothered by circumstances. Man has so modified circumstances that now ill-adjusted individuals of humanity are constrained to survive, and this survival of 'evil' is one of the great problems of social progress. We are entirely with Dr. Barnes in his plea for further research into the inheritance of feeble-mindedness, but we cannot see that his appeal to the gene has furthered the problems with which he deals. If genes are realities, it is impossible to say that they are the ultimate sources of variation; it is equally difficult to believe that the action of environment is less deterministic than the variation of the ultimate units of life; but and this lies at the foundation of the argument—there is no certainty in the statement that mutations are equally good and evil, or in the notion that they are causeless in the sense of being entirely fortuitous.

"SCIENCE and Modern Industry" was the subject taken by Sir William Pope for his Norman Lockyer lecture to the British Science Guild on Nov. 13. Modern man, he said in the course of the lecture, is to no appreciable degree the intellectual superior of his predecessor who lived in the far fringe of historic time. The invention of expressive and flexible languages, the existence of great literatures, the execution of gems of art, and the development of moral philosophy thousands of years ago, when compared with man's powers to-day, suggest that some forms of intellectual expression have long since been worked out to the utmost limit of the capacity of the human intelligence. In the study of the natural sciences, on the other hand, there finds expression a new faculty; the application of deductive reasoning to experimental observations carried out in accordance with a connected scheme and leading to an understanding of the ways of inanimate Nature is a new phase in man's intellectual history. The scientific age has provided us with a liberal supply of creature comforts, with more freedom from toil and more leisure than could have been dreamt of a century ago; moreover, it has seen the foundation of great industries. Modern industry, consisting in the application of science to industry, can serve national or international needs with economy and efficiency only when legislative or other control is exerted scientifically. Sir William Pope developed his argument by reference to the rise, decline, re-birth, and protected development of the coal-tar dyestuff industry in Great Britain, explaining the principal factors controlling the situation and the form of legislative assistance which has been accorded to the industry during the past ten years. The building up of a virile dyestuff industry in Great Britain has necessarily been accompanied by advantage to every branch of chemical industry and science, so that uncertainty whether the Government proposes or not to renew the relevant Act causes widespread embarrassment.

So much information concerning the manufacture and consumption of dyestuffs in Great Britain is available as to afford the practical certainty that the issue of national interest could be decided on questions of fact by a judicial body. "Scientifically-minded people," said Sir William Pope, "whether academic or industrial, have no convictions; they frame their conclusions and actions on the facts." Some of the great

industries of Great Britain, particularly the agricultural industry, are archaic in their methods and outlook; it is significant that in Germany agriculture is by far the largest domestic consumer of chemical products, whilst in England far too little advantage is being taken of artificial manures. Turning to the consideration of preparation for an industrial career, Sir William insisted on the profound distinction between education and instruction. The attainment of a mastery over general principles is a slow process, because it involves education, and the learning of experimental methods calls for long and laborious laboratory training, whilst theoretical organic chemistry, for example, offers an easy task to the youthful trained memory. It is common to find that the young man's handwriting and spelling are execrable, his knowledge of leading facts and ideas imperfect, and his knowledge of foreign languages quite inadequate, while he is stuffed with facts relating to highly specialised branches of science. Sir William Pope did not advocate a return to the classical and mathematical education of former days, but he asked that the schools should provide an education in the broad principles of the natural sciences and methods, supplemented by liberal and simple courses of practical work in the laboratory. Business men who had received a broad scientific education would find themselves capable of assessing at their true value many of the fantastic proposals which are continually being laid before financiers.

THE discovery of an unusual type of implement in the Swanscombe gravel pit at Northfleet, Kent, is announced in the *Times* of Nov. 6. Its interest lies in the fact that this type is unlike anything previously known in England or on the Continent, with the exception of certain implements found at Clacton-on-Sea by Mr. Hazzledine Warren, and others somewhat similar, also found by Mr. Warren, at Stoke Newington. The Abbé Breuil has therefore suggested the name 'Clactonian' for the new industry. The discovery was made by Mr. R. H. Chandler in the bottom gravels of the pit ten feet below the middle gravels in which St. Acheul hand-axes were found in excavations in 1913, of which characteristic examples are now in the British Museum. In these previous excavations some flakes only were found in the bottom gravels. The predominant tool in the present discovery is a species of chopper, of which the cutting edge has been produced by flaking a flint nodule with alternate strokes from right and left. Some of the flints are striated. The tools are associated with a warm fauna, the straight-tusked elephant, rhinoceros, and deer. Hence it is suggested that the striated tools may have been made before the Mindel glaciation, while those without striation and associated with the warm fauna may have belonged to the Mindel-Riss interglaciation. They would thus come between Chellean and Acheulean and might be classified as Early Acheulean.

THE October issue of *Man* is a special number devoted to India, embodying some of the results of the work of the Indian Research Committee of the Royal Anthropological Institute. For some time a special committee has been engaged in the investigation of Indian beads. It was with the assistance of this committee that Miss Caton-Thompson was enabled to arrive at a dating for the Rhodesian ruins at Zimbabwe. The number opens with a brief account of the work of the committee by Prof. J. L. Myres, president of the Royal Anthropological Institute, which is followed by a contribution by Mr. H. C. Beck, "Notes on Sundry Asiatic Beads," illustrated by two plates, of which one is a beautiful reproduction in colours of some of the more striking and important types. Mr Beck deals with beads from burial sites—megalithic, cairn, and urn burials—in India, the Malay Peninsula, and Sarawak. Some of the beads are of considerable antiquity, and Mr. Beck by comparative study traces them to their probable origin. Some of the beads show affinities with Crete, while others are of Roman origin. A series of articles by Mr. L. A. Cammiade describes the excavation of urn burial sites in Southern India, and particularly the Madras Presidency, from which some of the beads described by Mr. Beck were derived. The area of these urn burial sites was sometimes considerable, running to as much as a quarter of an acre. The urns were of various types, and inside the large urns were smaller urns, in one case as many as twenty-two in number. There were no signs of cremation.

THE custom of urn burial revealed by the excavations described by Mr. Cammiade is extremely interesting. In certain cases it is highly artificial, as Mr. Cammiade points out. While some of the large urns contained a body entire, in others—those in which the smaller urns were contained—the small bones, the phalanges and carpals, had been placed in small urns, the skull and some of the other bones were found among the contents of the urn, and the long bones were leaning against the internal sides of the urn. The culture of the cairn and urn burials of Southern India is discussed by Mr. K. de B. Codrington. He is of the opinion that they belong to a single culture complex in Southern India, presenting affinities with Northern India which it is not yet possible to work out. The date approaches somewhere about the borders of the historic period; it may be about 600 A.D. The burial customs appear to link up with modern practice; but the interesting feature is that they appear to be the final stage of the burial rite and to be communal, the bodies having been reserved until the time of interment came. The rich were interred entire; but of the poor, some of the bones only were interred symbolically.

DURING the naval review off Portland on Nov. 1, three battleships, the *Warspite*, *Barham*, and *Malaya*, were engaged from 3 P.M. to 3.20 P.M. in concentration firing from 15-inch guns. According to the *Times* correspondent on board the *Nelson*, which was little more than a mile from the firing ships, the reports did not seem unduly loud. They were heard, however, according to letters in recent issues of that paper, at considerable distances from Portland, the farthest place being Towcester in Northamptonshire (130

miles) and the nearest Littlehampton in Sussex (83 miles)—not unusual distances when a silent zone is developed. When plotted on a map, the 25 places are seen to lie within an oval area 113 miles long from north-west to south-east and 56 miles wide, the centre of the area being about one hundred miles north-east of Portland.

THE British Photographic Research Association has gone into voluntary liquidation; this decision has been reached in full accord between the Department of Scientific and Industrial Research and the manufacturer members of the Association. Two main factors have necessitated this decision. The first is that important changes have taken place in the organisation of the industry itself; manufacturing interests have been consolidated and as a result the number of separate firms interested in the work of the Association has been considerably reduced. The second factor is a very marked increase in the research work carried out in the laboratories of the manufacturing firms themselves—an increase which has, to a large extent, been the outcome of the work of the Association. This widening of the outlook of the industry with regard to research is one of the results which it was hoped the Association would achieve, and the development has been much fostered by the policy of the Director of the Association, Dr. T. Slater Price, in keeping the scientific staffs of the manufacturing firms in close touch with the research work carried out in the laboratories of the Association, and also with the latest scientific developments likely to have direct application to problems of the industry.

DR. PHILIP EGGLETON delivered an address before the Royal Society of Edinburgh on Nov. 3, on recent work in the biochemistry of muscle. In studying the muscular engine, two chemical systems which may prove to be quite distinct—have to be sought. One is responsible for the energy of contraction, an anærobic set of processes, and the other is concerned with the 'recharging' phase, oxidative recovery. The view that the formation of lactic acid from carbohydrate is the core of the former system, and its partial oxidation is the essence of the latter, has had to be seriously modified as a result of several recently reported facts, notably the discovery by Lundsgaard that in certain circumstances work may be done anaerobically by a muscle without the formation of any lactic acid. The newer additions to our knowledge do not weaken the hypothesis that the oxidation of lactic acid provides the energy for recuperation, but they necessitate a fresh search for the chemical contractile mechanism. It has been suggested by Meyerhof that the breakdown of phosphagen (which Lundsgaard observed even in the muscles incapable of lactic acid production) is a reaction capable of supplying the necessary energy for this phase. There are difficulties in the way of this suggestion, but the only alternative at present is to place the responsibility on some reaction, or set of reactions, as yet undiscovered.

THE presidential address of Sir George Humphreys to the members of the Institution of Civil Engineers on Nov. 4 was appropriately devoted to a review of the activities of the London County Council during the period of twenty-eight years in which Sir George has been associated with that body, for the later portion as its Chief Engineer and Administrator of Housing. The population of Greater London has increased from 6,600,000 in 1901 to nearly 8,000,000 at the present day, and the problems presented by its growth and redistribution have been of an extremely interesting character. Sir George reviewed the various spheres of administration and development, including the drainage area of 180 square miles, with its main outfalls at Barking and Crossness, pointing out that within the area surrounding the County (117 square miles) to a radial distance of 25 miles from Charing Cross, there are so many as two hundred separate sewage works, the effluents from which find their way into the Thames. The problem of making comprehensive provision for these and additional areas within the catchment basin is now engaging the attention of the Ministry of Health. As regards water supply, the greater part of the water for the 574 square miles served by the Metropolitan Water Board is drawn from the Thames and the remainder from the Lee and from wells. The Board has to-day available storage reservoirs for 19,657 million gallons, and despite some restriction of use in 1929, it has maintained a supply of about 100,000 million gallons of water per annum for a population of about 7½ millions. The Thames bridges, tunnels, and river protection works were alluded to, and the various public services, including transport, briefly surveyed. The address concluded with a reference to housing accommodation for the working classes, and stated that the contributions of the London County Council and the borough councils, since the War, had amounted to about 40,000 and 11,000 dwellings respectively, the former constituting, in a number of cases, small townships, such as the Becontree estate at Dagenham with 25,000 houses and the St. Helier estate near Morden with 10,000.

IN the recent presidential address to the Society for Psychical Research, delivered by Dr. Walter Prince, of Boston, U.S.A., which is printed in the Society's *Proceedings* for October, the speaker laid stress upon the unsatisfactory methods generally employed for the investigation of the so-called physical phenomena of spiritualism, and outlined a number of conditions which it would be desirable to demand. He compared the nature of the evidence as regards these alleged physical phenomena with that of certain of the mental phenomena, such as scrying and clairvoyance. With respect to these, he maintained that so far from explaining away the phenomena, psychical researchers have brought some of them far on the way to factual establishment. Dr. Prince considers that telepathy is proved, and attempts to dispose of many of the mental phenomena have been met with swift rebuttal. Continuing, Dr. Prince referred to a few cases which seem difficult to explain normally, and in conclusion stated that what is needed is more observation until finally the meaning and significance of the phenomena will become clear.

FROM *Věstník*, the publication of the Museum of Czechoslovakia, we learn that at an auspicious inauguration ceremony on May 4, an Agrarian Museum in Bratislava was thrown open to the people. The building of the museum has taken four years, and now ten rooms are devoted to general exhibits and four to a historical section. The aim of the museum is to inculcate in the peasantry a new interest in their own country, in the development of its agriculture, and in the struggles of their ancestors; and through these to promote further progress in agriculture. The care with which the museum has been planned, both as regards the buildings and the collections which they are to house, speaks well for the foresight of its organisers, and it is not surprising to learn that the Slovak peasants welcome the new cultural institution, which gives a feeling of unity and solidity to their industry. The opening of the museum was celebrated as a holiday by the Slovak peasantry and the whole agricultural population in Czechoslovakia.

"IN these times when our traditional human pairings are being so widely criticised and so boldly relaxed, there is a biological warning—Beware of Reversions." In the course of an article in the *Quarterly Review* for October, Sir J. Arthur Thomson recalls, in the light of recent researches, the trend of the evolution of sex in the animal kingdom. His excellent summary of the many-sided progression of sex structures and sex behaviour leads to conclusions which bear upon human affairs, for he is convinced that man, when willing to use science as his torch, has much to gain from a survey of the sub-human world of life. A wide survey of the evolution of sex throughout the animal kingdom shows the gradual enhancement of sex attraction by the addition of the psychological to the physiological, and by the addition of finer sympathies and synergies to the sensory attraction. Where a prolonged courtship is subtle, as Julian Huxley has shown it to be with the great crested grebe, it forges psychical bonds which last and keep the two birds loyal partners long after the sex-fondness has passed into abeyance. The main lesson of the evolution of sex, Sir Arthur concludes, is that fondness should rise into love, and that the earth-covered roots should feed a stem that bears the flowers of the spirit and the seeds of an evolving race.

AT the ordinary meeting of the Institution of Electrical Engineers to be held at 6 P.M. on Thursday, Nov. 20, an oil painting of Ampère will be presented to the Institution on behalf of Mr. E. Garcke. The portrait is by Mr. Edgard Maxence, Member of the Institute of France.

IT is announced in *Science* that the Abbé Henri Breuil, of the Institut de Paléontologie Humaine, Paris; Sir Arthur Keith, of the Royal College of Surgeons, London, and Prof. G. Elliot Smith, of University College, London, have been elected corresponding members of the Field Museum of Natural History, in recognition of services rendered to the museum.

SCIENCE Service announces that Admiral Watson Taylor, U.S.N., retired, has been awarded the John Fritz Medal for his outstanding achievement in marine architecture, particularly in relation to hull design, as Chief Constructor of the United States Navy during the War. The award is made by the four American societies of civil, mining and metallurgical, mechanical, and electrical engineers.

THE third Liversidge lecture of the Chemical Society, which was to have been delivered by Prof. H. B. Dixon, will be given at 5.30 P.M. on Dec. 11 by Prof. W. A. Bone, at the Imperial College of Science and Technology, South Kensington. Prof. Bone will take as his subject, "Fifty Years' Experimental Research upon the Influence of Steam on the Combustion of Carbonic Oxide (1880–1930)".

THE annual meeting of the Institution of Naval Architects will open on Wednesday, Mar. 25. At the invitation of the Association Technique Maritime et Aeronautique, the summer meeting will be held in Paris early in July 1931. The International Exhibition at Vincennes (near Paris) will add to the interest of the meeting, and it is proposed to visit one of the shipbuilding centres in France.

THE following officers for the session 1930–31 of the Philosophical Society, University of Durham, have been elected: *President*: The Hon. Sir Charles A. Parsons; *Hon. Secretary*: Mr. W. M. Madgin, Armstrong College, Newcastle-upon-Tyne; *Hon. Treasurer*: Mr. J. W. Bullerwell, Armstrong College, Newcastle-upon-Tyne; *Editor of Proceedings*: Prof. G. W. Todd; *Librarian*: Dr. F. Bradshaw.

AT a meeting of the Geological Society of London on Nov. 5, Prof. P. Lemoine, Paris, and Prof. G. A. F. Molengraaff, Delft, were elected foreign members of the Society; and Prof. R. S. Bassler, Washington (D.C.); Prof. O. Mügge, Göttingen; Dr. D. I. Mushketov, Leningrad; Madame M. Pavlov, Moscow; Prof. P. D. Quensel, Stockholm; and Prof. E. Stensiö, Stockholm, were elected foreign correspondents of the Society.

THE following appointments have recently been made by the Secretary of State for the Colonies: Mr. W. G. Higgins, to be agricultural field officer, Federated Malay States. Mr. C. M. Maggs, to be horticultural assistant, Federated Malay States. Mr. V. Liversage, to be agricultural economist, Kenya. Mr. F. B. Notley, to be assistant entomologist, Kenya. Mr. G. M. Roddan, to be provincial superintendent of agriculture, Sierra Leone. Mr. E. Harrison, deputy director of agriculture, Kenya, to be director of agriculture, Tanganyika Territory. Mr. G. W. Lock, to be district agricultural officer, Tanganyika Territory. Mr. R. P. Davidson and Mr. A. J. Kerr, to be agricultural officers, Uganda. Mr. G. Griffith, to be assistant agricultural chemist, Uganda. Mr. W. Small, mycologist, Ceylon, to be director of agriculture, Nyasaland. Mr. E. P. Hodgkin, to be entomologist (Medical Service), Kenya. Mr. M. E. Dommen, to be assistant conservator of forests, Cyprus.

IN the column of "Historic Natural Events" in NATURE of Nov. 8, p. 744, it is stated that Tycho Brahe discovered Nova Cassiopeiæ on Nov. 11, 1572, from Uraniborg. The observation was made, however, at the castle of Herritzvad, near Knudstrup, where Tycho Brahe's maternal uncle, Steno Bolle, had permitted him to instal a laboratory. The first stone of the observatory of Uraniborg was laid on Aug. 8, 1576.

THE *Guide to Current Official Statistics* is a very useful annual publication of H.M. Stationery Office (price 1*s*.). The volume for 1929 has now been issued. There are two main divisions of the guide. The larger part is occupied by a detailed subject index which gives the numbers of the relevant publications. In the second part these are serially listed with titles and contents. This arrangement makes it easy to discover if there is an official publication on any subject.

THE annual report for the year ended Mar. 31 last of the Executive Council of the National Institute for the Blind, 224-6-8 Great Portland Street, London, W.1, has recently been issued. The report gives an account of the work of the Institute, with a general description of its activities. Interesting information is given respecting the reproduction of literature in Braille and in Moon types, with several illustrations. Help is given by voluntary workers in the production of single Braille volumes: for example, a particular text-book for a blind student. It is only by means of an assured income that the splendid work of the Institute can be maintained and extended, and an appeal is made for continuous support, for which purpose the annual subscription is most valuable.

THE eleventh Annual Report of the Ministry of Health, 1929-1930, has recently been issued (London: H.M. Stationery Office. 4*s*. 6*d*. net). The report relates to the year ended on Mar. 31, 1930, and the subjects dealt with come under the main heads of public health, local government and local finance, poor law, national health insurance, and contributory pensions. The report is in the main a record of the more important business transacted by the Ministry during the year, and does not cover matters of routine or detail. In the section dealing with sale of foods and drugs, attention is directed to the considerable contamination by tin that may occur in cheeses wrapped in tin-foil. As in previous years, the Annual Report of the Chief Medical Officer of the Ministry is published separately.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A research student at the Institute of Pathology and Research, St. Mary's Hospital—The Secretary, Institute of Pathology and Research, St. Mary's Hospital, Paddington, W.2 (Nov. 17). A lecturer in dermatology in the University of Liverpool—The Registrar, The University, Liverpool (Nov. 19). An assistant at the Institute of Metals, for technical abstracting—The Secretary, Institute of Metals, 36 Victoria Street, S.W.1 (Nov. 20). An assistant curator in the Royal Botanic Gardens, Kew, in charge of the Herbaceous and Alpine Department—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1 (Nov. 24). A principal of the Stranmillis Training College, Belfast—The Secretary, Committee for the Training of Teachers, Ministry of Education, Parliament Buildings, Belfast (Dec. 1). A director of the Fuel Research Institute of the Union of South Africa—The Secretary, Office of the High Commissioner for the Union of South Africa, 73 Strand, W.C.2 (Dec. 15). An advisory entomologist in the University of Reading, under the scheme of the Ministry of Agriculture and Fisheries for the provision of technical advice to farmers—The Registrar, The University, Reading.

Our Astronomical Column.

Total Solar Eclipse of Oct. 21.—The *Daily Science News Bulletin* of Oct. 24, issued by Science Service, Washington, D.C., gives an account of the results obtained by the American party on the island of Niuafo'ou in the solar eclipse of Oct. 21. There had been rain shortly before totality, but it cleared in time, leaving only a very slight haze, which did not seriously interfere with the coronal photographs: these are stated to be of marvellous beauty; they were taken with the 63-ft. tower telescope and the 65-ft. horizontal one. The corona was of a type intermediate between maximum and minimum; there were streamers both to east and west, and a coronal dome shaped "like a gigantic strawberry" was a prominent feature. Prof. Mitchell secured excellent spectrograms with two concave gratings, extending from λ3200 to λ7800. They show more than thirty hydrogen lines and eight coronal lines. Structure can be traced in the image given by a coronal line in the green; a coronal disturbance is shown that appears to be connected with a prominence. The New Zealand party also secured successful spectrograms with a prismatic camera, but they are on a smaller scale than the American ones.

The Leonid Meteors of 1930.—Mr. W. F. Denning writes: "The shower of November meteors becomes due at the middle of the present month, though no brilliant display is to be anticipated. The group of meteors which originated the abundant exhibition of Nov. 13, 1866, was disturbed by the gravitational influence of the planet Jupiter and apparently drawn outside the earth's orbit, so that in 1899 or 1900 no striking returns were observed. In 1901, however, a somewhat plentiful outburst of meteors was noticed in America, while in 1903 the shower was witnessed in England. The numbers counted, however, fell far below those recorded in 1833 or 1866, and were quite of secondary importance. The part of the stream which may return this year will form the region in advance of the main clusters near the cometary nucleus and should be attentively observed, for it is important to ascertain whether or not the meteors are now more richly distributed along the orbit than in former years. This year the moon will be full nine days before the shower should recur with the greatest activity, and will rise on Nov. 15 at 0.34 A.M. and at 1.59 A.M. on Nov. 16. Observers who will watch the firmament either before or after these times will be certain to see a few fine Leonids, and possibly obtain some valuable data."

Research Items.

The Barren-Land Wolf of Canada.—In a recent instalment of his account of "An Expedition to Sub-arctic Canada" in 1924–25, Capt. J. C. Critchell-Bullock gives a lengthy account of the habits of the barren-land wolf (*Canadian Naturalist*, October 1930). He dismisses as highly exaggerated the stories of the viciousness of these wolves, which, well-fed or starved, always avoid a direct encounter with man. Very few authentic cases are on record of the killing of human beings, and apart from one case of a badly crippled man on the Mackenzie River many years ago, they apply to an occasional Indian or Eskimo child who had become waylaid during a blizzard and had fallen down. In such circumstances, even sleigh dogs at a trading post have been known to maul a woman, with fatal results. The barren-land wolf travels in packs of not more than eight or nine, and it seems reasonable to assume that these packs consist of parent wolves and their own litters. They breed during June, and the pups, generally born in a den amongst loose drift which can be readily tunnelled, are suckled for two months and then fed on meat or partially digested food regurgitated by the mother. At two years they are practically full-grown, and until they take mates, follow their parents. Wolves are not likely to be found breeding in any locality in greater numbers than about one pair to four square miles, and where food was scarcer, dens were found at intervals of about twelve miles. They make great inroads upon the caribou herds, and on the assumption that there are four million caribou in Canada and fifty thousand wolves, the author reckons that the annual kill amounts to some two and a half million caribou.

Control of Moles.—An account of some experiments in the control of moles, carried out by the Department of Agriculture and Horticulture of the University of Bristol, is given in the *Journal of the Ministry of Agriculture*, vol. 37, p. 646. A badly infested area was surrounded by a yard-wide trench, in the inside of which fine wire netting was erected to prevent the escape or re-entry of moles. Certain materials known to be effective in rodent control were used. Baits prepared from red squill, either as a liquid or powder, at the rate of ten parts per hundred of the powder, proved satisfactory, provided that considerable care was taken to avoid handling the soil or disturbing the run, it being found that if the naked hand rubbed the soil of the burrow, or the run was much disturbed, the moles escaped near this point. Gassing with 'cyano-gas' or 'horo-gas' was also effective in driving the moles from the runs; but for satisfactory results the process should also be carried out in the retreats of the moles under banks or in woods, for although the actual runs do not become re-infested after being gassed, the moles will tend to carry on their activities around the treated area. Trapping is considered quite satisfactory in the hands of an experienced person, and is recommended for large estates where there is sufficient work to justify the employment of a professional mole-catcher.

The Butterfly *Pieris rapæ* in New Zealand.—In the *Entomologists' Monthly Magazine* for October (p. 224), Mr. E. S. West records the capture of two examples of this common and destructive butterfly in New Zealand. They were taken in Napier, Hawke's Bay, and the record is one of considerable importance. Under a new and highly favourable environment there is a possibility of the insect establishing itself and becoming as great a pest as in Europe and North America. Doubtlessly the Department of Agriculture and the Cawthron Institute will take any steps desirable to ascertain whether the species has secured a footing or not, and will give advice as to any repression measures, should such prove necessary. The two examples recorded may prove to be merely odd specimens from a small batch that possibly got introduced in the egg stage. It is not unlikely that eggs of this species were present on Cruciferous vegetables in cold store on steamers plying between New Zealand and Honolulu or northern America, where this insect is common. On reaching a New Zealand port, vegetable debris discarded from steamers might provide the means of entry of the insect in question. *Pieris rapæ*, it may be added, has so far been unknown in Australasia. It became established in the Hawaiian Islands less than thirty years ago, where it most likely got introduced from California on cabbages or allied vegetables.

Northern Ostracods.—An account of the Ostracoda of the North Sea and Baltic forms a recent part of "Die Tierwelt der Nord- und Ostsee" (Begründet von G. Grimpe und E. Wagler. Lief. 16, 10 b. Ostracoda von Walter Klie, Bremerhaven. Leipzig: Akademische Verlagsgesellschaft, m.b.H., 1929), numerous species being recorded, but not all differentiated. The systematic part, which takes up rather more than half the memoir, contains diagnoses of the main groups and keys to the genera, with figures, chiefly after G. O. Sars, of representative forms or of their characteristic appendages, 45 genera and 172 species being included. The remaining portion, besides dealing briefly with methods of collecting and technique, is taken up by descriptions of the morphology, physiology, life-histories, and general bionomics of these animals, with notes on habitat and distribution. No mention is made of Prof. H. Graham Cannon's work dealing with important points both of anatomy and feeding mechanisms. Much more is known about freshwater ostracods than of the marine forms, information being very scanty, especially as to the life-histories of the latter. All those in the district described are bottom forms except the Conchœcidæ and *Philomedes globosus* in the Cypridinidæ, which are pelagic. More workers are much wanted to further our knowledge of the marine ostracods, and they would probably be amply repaid by taking up the subject in detail.

Resistance of Statoblasts to Unfavourable Conditions.—In the course of observations on the statoblasts of the largest of the colonial freshwater Polyzoa, *Pectinatella magnifica*, Chandler M. Brooks made several tests to determine their resistance to unfavourable conditions of temperature and of drought (*Proc. Acad. Nat. Sci. Philadelphia*, vol. 81, p. 427, 1930). It has been generally supposed that the statoblasts of freshwater Polyzoa must be frozen or at least go through a considerable period of rest before they will hatch. Specimens kept at 22° C. until about ready to hatch, hatched under normal conditions although the temperature fell to freezing point, while those not kept in the warm room failed to hatch. Even the lowest temperature produced by an ice and salt mixture did not kill statoblasts exposed to it for any length of time, but even at 10° C. they developed very slowly. Heating above 40° C. retarded development, and at 55° C. death resulted. It would appear, therefore, that statoblasts develop steadily from the time they are formed, just as buds do, but the speed of development is greatly influenced by the temperature, and the

retardation due to excessive cold explains the lack of hatching in autumn. As regards drought, undried statoblasts hatched in eight days; dried for one week, in twelve days; for three weeks, in nineteen days; for five weeks (when they could be broken and ground to dust), in twenty-three days. The polypids are much more sensitive, enduring 10° C. for a short time only and dying at once at 45° C., so that the statoblasts clearly have a positive protective function.

Fruit Storage.—The home storage of apples and pears is an all-important question at this time of the year, and much waste can be avoided if attention is paid to a few general rules supplied by the Ministry of Agriculture. Care in choosing the right time for picking is essential if storage is to be successful. The fruit should come away from the tree easily on gently lifting, every precaution being taken to avoid bruising, as the careful storage of damaged fruit is only trouble wasted. A cool cellar or shed with a good roof and earthen, concrete, or brick floor is best, since wooden-floored buildings, especially dwelling-houses, are apt to be too dry. Pears, however, can be kept under slightly drier conditions than apples. The atmosphere should be rather moist, and during the first three weeks, at least, considerable ventilation is essential. A cool, even temperature is desirable, and the fruit should be kept in complete or partial darkness. Before placing in store, the fruit should be allowed to cool off in an airy place. Each sound specimen is then wrapped in a separate piece of clean tissue paper and they can be packed several rows deep on shelves or in boxes. Pears, in particular, need frequent inspection, as their ripe period is so short-lived. They are best stored spread out in shallow boxes. Wrappers for fruit storage, cut to a convenient size, can be obtained from most horticultural sales-

Sugar Beet in England.—The financial results of sugar beet growing in the eastern counties of England have been investigated for the three years 1927–29, and are reported on by C. Burgess and P. E. Graves in Report No. 16, Farm Economics Branch, University of Cambridge, Department of Agriculture. Data have been supplied by one hundred and fifty-two farmers, and more than ten thousand completed forms have been supplied and analysed statistically. The report first gives a statistical rendering of the field data, manuring, yield, sugar content, and soil classes, which provide the theoretical basis for the work. Other factors concerned are the influence of time of delivery upon sugar content, weather conditions during growth, and cost of haulage and transport. After a consideration of the over-all costs and the receipts and profits per acre and per ton, the results are grouped for the different soil types. This leads to the practical aspect of the factors influencing costs and returns, such as manuring, rate of seeding, methods of cultivation, etc., together with the difficulties due to the seasonal distribution of labour required for sugar beet. The second reduction in the rate of subsidy comes into operation with the 1931 crop. There has been a considerable extension in the acreage under sugar beet, but it is considered that it would be unwise to press for too great a reduction on the present price of sugar beet on this score, since maximum production is essential to economic factory operation, and lower prices might entail a reduction of acreage and consequent reduction in supply. It is to the interest of the factory to offer a price which will maintain the acreage of beet at a maximum, and in the interest of the farmer to maintain a high production to enable factories to be run economically, so that the interests of the two parties are in reality identical.

Form of the Japan Arc.—Though the term 'Japan arc' has been used by Naumann and others for nearly fifty years, no attempt seems to have been made to determine its exact form until the task was undertaken by Mr. N. Kumagai, of the Geological Institute, Kyoto Imperial University (*Jap. Jour. Ast. and Geophys.*, vol. 8, pp. 1-28; 1930). The boundaries of the four main islands, Kyusyu, Sikoku, Honsyu, and Hokkaido, are taken to be the bathymetric lines of 200 metres on either side, for at this depth there is an abrupt increase in the slope of the ocean-bed. The central axis of Japan is defined as the locus of points midway between the marginal arcs. The means of every three of the points corresponding to each half-degree were calculated and when plotted on a map were found to lie nearly along the arc of a small circle, the pole of which lies in lat. 42° 37′ N., long. 130° 23′ E., the polar distance of the circle being 8° 46′. In the same way, Mr. Kumagai finds the boundaries of the arc to correspond closely with two parallel small circles, the distance between them being 178 miles, while the total length of the Japan arc, from the west end of Kyusyu to the north end of Hokkaido, is 1300 miles. In a second discussion, the island of Hokkaido is excluded, as its boundaries deviate slightly from the above small circles. It is then found that both boundaries and central axis agree much more closely with parallel small circles, the pole of which is in lat. 41° 0′ N., long. 131° 46′ E., the distance between the marginal arcs being the same as before, and the length of the arc not less than 986 miles.

Granite Intrusions of the Adirondacks.—In the *New York State Museum Bull.* No. 281, 1929, Dr. A. F. Buddington presents the results of five years of field work in the foothills of the north-west Adirondacks, south-east of the St. Lawrence and parallel to it. Here there is a belt of Grenville formations invaded by fourteen elongated granite masses. The latter are interpreted as phacoliths resulting from intrusions of magma in the crests of anticlinal folds with subsequent intense deformation before the complete consolidation of the magma. The granite bodies are restricted to the folds, limbs and noses both presenting conformity with the bedding of the invaded rocks. In one case the base of a phacolith is clearly exposed. On the other hand, there is scarcely a trace of cataclastic structure in the granites and such foliation as occurs is shown to have developed before consolidation. The phenomena to be expected at the surfaces of batholiths are absent. Along much of the contact between granite and limestone there is a narrow zone, up to 150 feet in width, that consists of hornblende- or pyroxene-gneiss, accompanied by sills and lenses of granite and pegmatite and sheets of garnet-sillimanite-gneiss. Metasomatic replacement of limestone by residual solutions carrying volatile compounds thus appears to be indicated.

New Jersey Barnacles.—Mr. Horace G. Richards (*Proceedings of the Academy of Natural Sciences of Philadelphia*, vol. 82, 1930) notes the habitat of several barnacles, particularly *Platylepas hexastylos* on the skull of the green turtle *Chelonia mydas*. This is the first time that this species has been seen *in situ* on a turtle although it was known to live attached to them. The more common turtle barnacle *Chelonibia testudinaria*, which lives attached to the shell of turtles, was found on a large specimen, probably the loggerhead (*Caretta caretta*), taken by a fisherman. The rock barnacle *Balanus balanoides* has recently been found where rock jetties have been built along the sandy shores, although previously absent on account of the uncongenial surroundings. *Balanus eburneus* is the commonest barnacle in these districts.

Mollusca of Jasper Park.—The Jasper National Park, Alberta, Canada, save for the birds and mammals, has been biologically a *terra incognita*, so that advantage was taken of expeditions to the Park in 1925–26 to study as many of the animal groups as possible and Mr. Alan Mozley now reports on the mollusca collected in and around certain of its lakes (*Trans. Roy. Soc. Edinb.*, vol. 56). About forty species and varieties are enumerated and described and some are figured in order to show their typical form and variations in the region, while an account of their habitats and other phases of their ecology is promised in a later communication.

Atmospheric Pollution.—The Report of the Atmospheric Pollution Committee of the Department of Scientific and Industrial Research for the year ending March 1929 was published on Oct. 28. It shows that of the principal towns of Great Britain at which observations of the dust particles which fall to the ground from the air in a month are made, only a few have districts in which the deposit is less than 12·7 tons per square mile per month. These are Bournville and West Heath, Birmingham; Garston, Watford; Headingley, Leeds; Western Park, Leicester; Rothamsted; Hesketh Park, Southport; and Clarence Park, Wakefield. The great majority of the stations, for example, London (including Kew), Cardiff, Edinburgh, Glasgow, Rochdale, Stoke-on-Trent, and the central parts of Leeds, Leicester, Birmingham, and Wakefield have deposits from one to three times, Liverpool, St. Helens, and the centre of Rochdale have from three to five times, while City Road, Newcastle-on-Tyne, has more than five times the above. The average amount of suspended sooty impurity in the air of, for example, London or Stoke-on-Trent on a winter day, is about half a milligram per cubic metre, domestic smoke being 2·5 times as much as industrial smoke in London and 3·5 in Glasgow, while towns like Leeds get about 25 per cent more sunshine in the outskirts than in the centre.

The Boiling Point of Water.—Although the boiling points of water under pressures between 68 cm. and 83 cm. of mercury are generally given to 0·001° C., there are discrepancies of the order of 0·01° C. between the values given by different observers. In order to decide between the alternative values, Messrs. A. Zamaczinsky and A. Bonhoure have made a new series of observations, using the glass hypsometer of M. Swietoslawski, in which the boiling process projects the steam and hot water against the thermometer tube. The temperature is measured by platinum thermometers, the pressure of the atmosphere by a standard barometer, and the deviation from it by a water manometer. To prevent superheating of the water, the inside surface of the hypsometer is covered with powdered glass. The results agree to within 0·002° C. with those given by M. Volet as the result of the observations of Chappuis and referred to in the notice of vol. 18 of the *Travaux et mémoires* of the Bureau International des Poids et Mesures (NATURE, 125, p. 948). The authors agree with M. Volet that a trinomial in the pressure is necessary to express the results. They give a table of boiling points between 68 cm. and 83 cm. mercury pressure by steps of 0·1 cm. in the September issue of the *Journal de Physique*.

Determination of Unsaturated Hydrocarbons.—*Technical Paper on Fuel Research*, No. 28 (Department of Scientific and Industrial Research. London: H.M. Stationery Office, 1930, 4*d*.), by A. B. Manning and F. M. E. Shepherd, on the determination of aromatic, unsaturated, and naphthene hydrocarbons in light oils and motor spirits, deals principally with light oils from the carbonisation and hydrogenation of coal, only two examples of motor spirit being metnioned. The principle of the method is absorption from vapours, similar to ordinary gas analysis. Further investigation of the application of the methods to petroleum products would undoubtedly be of interest.

Critical Constants of Fluorine.—The boiling point of fluorine was given by Moissan and Dewar in 1897 as approximately −187°, but no other measurements of the vapour pressure of this element have been made. In the October number of the *Journal of the American Chemical Society*, Cady and Hildebrand describe the preparation of fluorine in quantity and the measurements of its vapour pressure. They calculate the boiling point as −188·2°, and point out that this is in good agreement with Moissan and Dewar's value corrected to the new values for the vapour pressure of oxygen, which gives −188·0°. The critical temperature and pressure are found by direct experiments to be approximately −129·1° and 55 atm., the latent heat of evaporation at the boiling point being 1540 gm. cal. per mol.

An Electrically Driven Sifting Machine.—In the *Chemiker-Zeitung* for Oct. 15 will be found the description of a new electrically driven sifting machine which is likely to be of great use in chemical factories and laboratories. It is made in various sizes and can be adapted to take sieves of different shapes. It can be suspended from above and may be transported along an overhead rail. The vertical motor is enclosed in a dust-proof casing and both it and the container which moves the sieve are mounted on ball-bearings. Shaking is effected by means of an enclosed excentric device, with a special arrangement to guard against transference of any of the vibration to the motor. Any ordinary hand-sieve up to a diameter of 54 cm. can be fixed to the model and readily interchanged. The machine is made by Messrs. A. C. Fraissinet, of Chemnitz.

Furnace Atmospheres and the Production of Scale.—At a joint meeting of the Yorkshire and Fuel Sections of the Society of Chemical Industry held in Leeds on Oct. 27, a paper on the influence of different furnace atmospheres in the heating of metals, particularly steel, by Dr. W. H. Blackburn and Prof. J. W. Cobb, of the Fuel Department, University of Leeds, was read. Typical furnace atmospheres reproduced in the laboratory show that it is of paramount importance that free oxygen should not reach the surface of the hot metal, indicating the necessity of not using more air than is necessary to complete combustion. A fuel rich in carbon and poor in hydrogen, as, for example, dry coke used in a fire or gas-producer blown with air and no steam, produces definitely less scale than a fuel richer in hydrogen, such as oil or bituminous coal. Special experiments showed that the free carbon suspended in the atmosphere of a furnace working with a smoky flame plays little or no part in making that flame protective against scaling, the protection being due to the reducing gases present. There seems thus to be no ground for the common assumption that a smoky flame from bituminous coal is more effective in minimising scale than a clean reducing flame from coke, which latter would, indeed, tend to be more protective on account of its lower content of water vapour. This contention is important in connexion with the possibility of minimising smoke from industrial furnaces.

Furunculosis in Freshwater Fishes.

THE Interim Report issued in March last (Edinburgh: His Majesty's Stationery Office) of the Furunculosis Committee appointed in July 1929, by the Right Hon. William Adamson and the Right Hon. Noel Buxton, contains a large amount of information on the damage done by this disease and the means of its dissemination, with suggestions for its suppression. The Committee was constituted "to investigate the origin, predisposing causes and mode of dissemination of furunculosis and similar infectious diseases among salmon, trout and other freshwater fish in England and Scotland, and to conduct experiments with a view to ascertaining methods of combating the disease, and to report the results of their proceedings".

Previous to the formation of this Committee, much information and experimental data were collected by a smaller and informal committee between the summer of 1928 and July 1929, certain members of which are on the present committee, and the services of Miss I. J. F. Williamson, who has been the research worker throughout, are retained, with a laboratory placed at the disposal of the committee in the Bacteriological Department of the University of Edinburgh, where recently accommodation for live fish has been arranged.

Furunculosis among freshwater fish had been known on the Continent for at least forty years, almost solely on fish farms, later in Bavarian rivers, and in 1910 in France and Switzerland. A severe outbreak in four rivers in the south-west of England in 1911 directed attention to the disease, which had been known in Great Britain, in a much less severe form, probably among trout in the chalk stream, a few years earlier. In 1911 investigations were carried on, and *Bacillus salmonicida*, the same organism as had been found to be the cause in Germany, was identified. Later the disease was recorded from Ireland, Wales, and Scotland and assumed an important aspect.

Furunculosis in the salmon and other freshwater fish is thus caused by the bacterium *Bacillus salmonicida*, which invades the blood stream and is distributed throughout the body. Lesions forming focal areas of necrosis in the skin and underlying muscles are set up, causing death. The bacillus can be isolated and cultivated artificially. It can be present in outwardly healthy fish, these being 'carriers' of the disease. Gobies were infected in the laboratory by these carriers.

The Salmonidæ are chiefly infected, particularly the genus *Salmo*, both *Salmo salar* (salmon) and *Salmo fario* (brown trout) being frequent victims, also other freshwater species to a less degree, but not purely marine forms. The eel, *Anguilla vulgaris*, has been experimentally infected, as have certain other marine fish.

Healthy fish placed in water with infected individuals may contract the disease. Set free in fresh water, the parasite may survive for a sufficient period to allow of its widespread distribution. Outbreaks usually occur from the end of May to October and there is a relative quiescence during winter and spring, but the disease may persist throughout the year in any given area. Thus it is enzootic but may be epizootic. There is no evidence of the passage of the organism through an intermediate host. It may be assumed that infection is spread by contact of infected and healthy fish or by the discharge of the specific organism from the body of infected fish into the water.

Temperature is an important factor, warm dry weather favouring the disease. Overstocking and overcrowding also helps in spreading it to a large extent. All kinds of rivers and streams may harbour it. So far, river pollution seems to be unimportant in favouring its growth.

It is probable that salmon from the sea become rapidly infected in fresh water and the change of environment may increase susceptibility. All evidence favours the theory that infection is introduced into the area concerned by some means other than natural. When once there it may spread by many methods. Possibly infection may come from the introduction of a fish from a farm known to be infected.

It is of immense economic importance for our fisheries to get rid of this disease. In one river when in the ordinary course every fish would spawn, as many as 700 salmon have been picked up dead in a single season, the average annual loss being 400 fish, and the trout fisheries also suffer to a large extent.

The recommendations of the Committee as to means of control are: the collection of further evidence regarding the distribution of the disease; control of all possible sources of infection; eradication of the disease when present in fish farms by destroying the fish and emptying and disinfecting the tank or pond, and the immediate removal of dead and dying fish from the rivers; amelioration of conditions possibly favouring outbreaks when infection is already present, especially overcrowding; the control or prohibition of the importation of live fish from abroad, and the provision of powers to inspect and examine fish from artificial and natural waters, especially fish farms which are the usual sources of stock fish; finally, the maintenance of a central laboratory where routine examination of fish can be carried out and research prosecuted.

Upper Air Investigations in Egypt.

A PUBLICATION entitled "Upper Winds at Cairo and Khartoum", which constitutes Paper No. 27 of the Physical Department of the Ministry of Public Works, Egypt, has been issued. It summarises the results of many thousands of measurements of upper wind made with the aid of pilot balloons at Helwân (25 km. south of Cairo) and Khartoum, the author being L. J. Sutton, director of the Egyptian Meteorological Service. The bulk of the paper is made up of statistical tables showing the frequency of occurrence of winds from the different directions, and the frequency of different speeds from each of the directions at various heights. There are also figures showing the resultant winds in each month at the surface, 500 metres, 1000 metres, and so on up to about 4000 or 5000 metres; and in the case of Khartoum, mean values for the rainy season (May–October) and the dry season (November–April).

The meteorological value of a work of this kind is largely represented by the extent to which it enables a more accurate picture of the general circulation of the atmosphere to be given in standard works on meteorology such as Shaw's recently completed "Manual of Meteorology". The statistics given in this case in regard to the mean wind at 3000 metres and 5000 metres in January at Helwân, agree with a figure in vol. 2 of that manual (Fig. 164, p. 259), in so far as they confirm the existence of a prevailing

westerly wind in northern Egypt at the 4000 metre level, in spite of the dominance of northerly winds from 500 metres to 2000 metres. The resultant at 4000 metres height is not far from due west in any month, and on an average for the whole year must be almost exactly from west.

At Khartoum conditions aloft are complicated by the complete seasonal change occasioned by the northward and southward movements of the equatorial wind circulations in accordance with the varying declination of the sun. In the rainy season the resultant has an easterly component from 3000 to 5000 metres, and is on an average nearly due east between 4000 metres and 5000 metres from July to September. Shaw's "Manual" does not give the mean pressure distribution at 4000 metres in July for the northern hemisphere, so a similar comparison cannot be made for that level. There is, however, a diagram for 8000 metres. If the latter is correct, one would expect light northerly winds to predominate above the easterlies found by Sutton. It is possible that these exist, but it may be noted that Sutton's resultant direction for July backs from nearly north-east to a little south of east, on passing from 4000 metres to 5000 metres, and it appears more probable that the diagram in question (Fig. 167, p. 162 of vol. 2) requires slight modification in view of Sutton's statistics.

In the dry season at Khartoum it appears that westerly or north-westerly winds prevail at about 3000 to 4000 metres, not winds from between west and south-west, as is implied by the figure in Shaw's "Manual" referred to earlier in this notice, which gives the pressure distribution at 4000 metres in January. It may be noted that Teisserenc de Bort is the authority on which Shaw based his diagrams. It is to be hoped that someone will be willing presently to revise our notions of mean air movement at 4000 metres and 8000 metres over Africa in the light of such valuable papers as this, when more of the younger meteorological services have carried on systematic soundings for a long series of years.

Drift Bottle Experiments in the Gulf of Mannar.

MR. A. H. MALPAS, in his work entitled "Preliminary Account of the Results of Drift Bottle Experiments in the Gulf of Mannar" (*Ceylon Journal of Science*—Section C, Fisheries: Bulletin of the Ceylon Fisheries, vol. 4, April 1930), describes the continuation of the experiments initiated by Mr. James Hornell in 1907. The recent researches have been on a much larger scale, drift bottles being liberated, so far as was practicable, throughout the year from 1913 until 1927 (except for the years 1917–19) and the area extended to include the whole of the portion of the Gulf above the Colombo-Tuticorin line, in order to obtain some idea of the monthly current changes.

In the Gulf of Mannar there is a more or less regular cyclic movement of water controlled by the north-east and south-west monsoons. The effect of the south-west monsoon, which has its maximum in July–August, is to force oceanic water of high salinity and low temperature into the Gulf, whilst with the north-east monsoon with its maximum in December–January the surface water is replaced by water of a low salinity. The oceanic current operates chiefly in the southern portion of the Gulf and rarely penetrates so far north as the pearl banks. There is, however, a definite surface drift over the pearl banks area due to the wind, and the banks lack protection from the violence of the south-west monsoon, which at its height makes the waters at the bottom turbid and may cause silting.

Under favourable conditions of south-west monsoon and current in July and August, the pelagic larvæ liberated at Tuticorin might reach Ceylon and settle as spat, and, conversely, Tuticorin might receive spat from Ceylon in December and January during the north-east monsoon.

In analysing the drift for each month of the year, the direction of drift of each bottle recovered is assumed to be from the point of liberation to the point of recovery, and naturally no allowance is made for the various possible changes in direction of drift between liberation and recovery.

The number of recovered bottles during the period of the north-east monsoon was small and these indicate no marked currents in the Gulf opposed to the prevailing north-east winds which would carry the bottles to either the Indian or Ceylon coasts. Many were probably carried out into the ocean and so lost. The period from March to April is transitional between the two monsoons with an average of south-west winds, the returns indicating a change of drift from south-west to north-north-east. In the pearl banks area and up the Ceylon coast the current was northerly with a slight westerly tendency. The 'little monsoon' sets in at the end of April with wind and rain and a pronounced north-east drift. The south-west monsoon from May to October opens with a burst of rain and wind about the middle of May, through June gradually becoming stronger until its full force is reached towards the end of July and beginning of August, then weakens and dies away in October: average wind south-west in May–July, more westerly in August–October. The bottle returns indicate north to north-east drift, becoming more easterly as we proceed north-west across the Gulf.

On the whole, the results of the bottle returns are in agreement with the Admiralty interpretations.

British Archæology.

AMONG the numerous papers on British archæology read before Section H (Anthropology) of the British Association at the recent Bristol meeting, two are of special interest. (1) Mr. C. W. Phillips, in discussing "Earthworks on Walton Common Down, near Clevedon", pointed out the great importance of air photography. On Walton Common Down, 250 feet above sea-level, is a group of earthworks in the form of a roughly circular enclosure 340 feet in diameter, with an entrance on the south-south-west side. An avenue formed by banks of similar construction projects from it 100 yards to the north-east and ends in a cross bank. A disc barrow stands to the north of the avenue and a partially destroyed rhomboidal earthwork to the south.

Until the site had been examined from the air, it was considered that the circle and avenue might be the remains of an ancient sacred place, but air photography proved a wholesome corrective by showing that outlying portions of one of the groups of Celtic fields underlie the earthworks, which are thus subsequent in date. Both air photography and field work show intensive remains of Celtic cultivation on the Common Down, associated with two groups of proved hut circles. It is suggested that the cross bank and avenue might have been devices for marshal-

ling and sorting sheep, similar works in Ireland being known to be thus associated.

(2) Mrs. E. M. Clifford's paper on prehistoric discoveries at Barnwood, Gloucester, opened up possibilities of decisive evidence as to the physical type of the native British who were living in the district when the Roman legions reached Gloucester (Glevum). The site lies by the side of the Roman road leading from Gloucester to Cirencester, It is an extensive flat field two miles distant from the Severn and 80 feet above the level of that river. The field has been excavated to a depth of 8 feet by the Gloucester Stone Company, and the discoveries reported by Mrs. Clifford were made during operations.

A section shows an upper foot of soil, then 2–3 feet of brick-earth, then bedded gravels, upper and lower. The lower gravels are rich in remains of mid-Pleistocene fauna; in the gravels and brick-earths have been found Acheulean, Mousterian, and Aurignacian stone implements. No human remains of Pleistocene date have been discovered as yet, but burials of a later date—of the early bronze age period (a beaker burial), of La Tène II.—and an extensive Roman cemetery (first and second century A.D.) have been carefully examined. In the Roman cemetery more than 100 inhumations and 50 cremations have been studied.

Sir Arthur Keith visited the site after the British Association meetings and considers it to be of great historical importance. He thinks that the evidence points to the people buried in the cemetery as being native British, thus giving a complete picture of the kind of people who lived in the west of Britain when the Romans reached Glevum. Mrs. Clifford acknowledged expert assistance received from Sir Arthur Keith, Mr. J. W. Gray, Prof. L. S. Palmer, the late Dr. C. W. Andrews, and Mr. Reginald A. Smith.

'Serialism.'

THE work entitled "An Experiment with Time", published in 1927, in which numerous remarkable instances were given of dreams that had occurred prior to the occurrence of the events corresponding to them in waking experience, will be familiar to many readers of NATURE. In order to account for these phenomena, the author of the book, Mr. J. W. Dunne, propounded in it a theory, which he designated 'serialism'; and he has recently been giving broadcast talks in further elucidation of his theory.

Mr. Dunne maintains that, so far from being a fallacy, an infinite regress is traceable not only in the nature of physical existence but also in the nature of our awareness of the physical world. The physical world is, he argues, so constituted that it can be viewed as a series of more and more fundamental worlds; and can, in fact, be understood only when examination of it is carried so far as the second term of the series. The process of scientific investigation consists, he urges, essentially of two steps—the search for the truly 'given', or compulsory, elements in our knowledge, and the description of such given knowledge as knowledge of an existing world. The awareness that some of our knowledge is compulsory is itself second-term knowledge. Thus, knowledge of a real external world and knowledge of the self are correlative—both are given in willed activity, primarily the activity of attention. The ultimate will and the ultimate physical entity that is the opposite will belong to the realm of indefinable 'being', which the defined fields of physical and psychical ence are to be extracted.

The second-term field of physics exhibits entities plainly regressive character; moreover, it does not constitute a closed physical system, but discloses gaps in its continuity, and these gaps indicate where there may be voluntary intervention. If the physical world be described in terms of matter, the regress comes to light when matter is derived from a submatter, called space, and this again from a sub-space, and so on.

The most striking confirmation of the theory is, however, afforded, Mr. Dunne thinks, by an analysis of the time regress. If we say of an event that it is happening 'now', we are adding something to the simple notion of a time-order; and the 'now-mark', which characterises the first-term field of physical existence, must itself travel. When, in the series of events *A B C*, *B* is now and later *C* is now, they are earlier and later in a more fundamental time, in which all that is past and future in the lesser time coexists. In modern physics the importance of the 'now-mark' has, it is contended, become readily apparent; for the probable structure of *B* depends very largely upon *B*'s position with regard to a 'now'. Many paths which a particle may take when *A* is 'now' are no longer open when *C* has become 'now'.

University and Educational Intelligence.

CAMBRIDGE.—The Adam Smith Prize has been awarded to Miss R. L. Cohen, of Newnham College, for an essay entitled "Factors affecting the Price of Potatoes in Great Britain".

At St. John's College the following have been elected into fellowships: W. D. V. Hodge, Wrangler with distinction, Part II. Mathematical Tripos 1925, Smith's Prize 1927; J. G. Semple, Wrangler with distinction, Part II. Mathematical Tripos 1927, Rayleigh Prize 1929; P. E. Vernon, Natural Sciences Tripos Part I., 1926, Class 1, Moral Sciences Tripos Part II., 1927, Class 1, Rockefeller Foundation Fellowship in Social Sciences at Yale University 1929.

The Henry Sidgwick Memorial Lecture at Newnham College will be given by Prof. A. V. Hill, professor of physiology in the University of London, on Saturday, Nov. 22, at 5 P.M. The title of the lecture is "Biology in Education".

LEEDS.—Under the will of the late Lord Brotherton, who died on Oct. 21 last, the University is to receive £100,000 for general purposes. This benefaction will be additional to the gift of the University Library, his collection of books, and an endowment for upkeep.

OXFORD.—At the meeting of Congregation on Nov. 4, a decree was passed providing that £2000 of an anonymous gift to the University of £5000 should be invested and the income used for the purchase of scientific books and periodicals. Another decree was passed giving power to the Vice-Chancellor to make provision for carrying on the duties of the Savilian professorship of astronomy during the vacancy caused by the death of Prof. H. H. Turner.

THE Prince of Wales has consented to become president of the fourth Congress of Universities of the Empire to be held in Edinburgh next summer, and, circumstances permitting, to welcome and address the delegates and representatives in London on July 3.

PROF. L. M. DENNIS, of the Department of Chemistry, Cornell University, informs us that the following have accepted appointment to the George Fisher Baker Non-Resident Lectureship in Chemistry at Cornell University for the next two years: first term, 1930–1931, Prof. G. Hevesy, Freiburg in Breisgau; second

term, 1930–1931, Dr. N. V. Sidgwick, Lincoln College, Oxford; first term, 1931–32, Prof. W. L. Bragg, Manchester; second term, 1931–32, Prof. Alfred Stock, Technische Hochschule, Karlsruhe; first term, 1932–33, Prof. Cecil H. Desch, Sheffield; second term, 1932–33, Prof. Otto Hahn, Kaiser Wilhelm Institut für Chemie, Berlin-Dahlem; first term, 1933–34, Prof. V. M. Goldschmidt, Göttingen; second term, 1933–34, Prof. Robert Robinson, Oxford.

Historic Natural Events.

Nov. 16-18, 1928. Storms over British Isles.—This was a very stormy period over the British Isles and neighbouring parts of Europe. A deep barometric depression lay north of Scotland and a series of intense secondaries crossed England and the southern North Sea, bringing winds of nearly 90 miles per hour in gusts. This storm caused much damage, especially to shipping, in Germany and Holland, with some loss of life. In Holland and Schleswig-Holstein the dykes burst in several places, with flooding.

Nov. 17, 1218. Storm Flood in North Sea.—Several parishes were overwhelmed by the sea, and many thousands of persons lost their lives. This storm broke through the West Frisian Islands, and formed the beginning of the Zuyder Zee.

Nov. 17-18, 1852. "Duke of Wellington's Flood".—During one of the highest Thames floods on record, on the occasion of the Duke of Wellington's funeral, the hearse and horses were upset in the flooded Bath Road at Maidenhead. At Putney the towing path was six feet under water, and the Great Western Railway line was flooded for four miles between Hanwell and Paddington. At Windsor part of the Home Park was four feet under water. Oxford was described as standing in a sea of water, the whole of the surrounding country being flooded, and the Evenlode Valley was for more than a week like an immense lake.

Nov. 17, 1882. Sunspot, Magnetic Storm, and Aurora.—A remarkable sunspot, visible to the naked eye, was reported on Nov. 17 and the following days. It was the largest spot hitherto photographed at Greenwich, its area being 2470 millionths of the sun's visible surface, and was exceptionally brilliant. Simultaneously both Europe and North America were visited by a violent magnetic storm, which began on Nov. 11 and reached its climax between 10 h. 30 m. on Nov. 17 and 5 h. 30 m. on Nov. 18. The magnetic declination oscillated rapidly through almost 2°, and the changes of force were correspondingly great and sudden. The whole telegraphic system was disturbed to an extent far exceeding anything previously recorded. Equally remarkable was the display of aurora on the evening of Nov. 17. As observed at the Royal Observatory, Greenwich, it commenced with a bright glow of red light extending from the north and west beyond the zenith, interspersed with pale green phosphorescent light and streamers. At 18 h. 40 m. a very brilliant streak of greenish light about 20° long appeared in the east-north-east and travelled rapidly towards the west. This streak was very widely observed over the British Isles; it passed from horizon to horizon in about six seconds, its height was of the order of 200 miles, and its velocity over a path of 200 miles about 15 miles per second. In North America the aurora was also very brilliant, and about midnight, in Michigan, all the visible heavens, to within 20° of the southern horizon, were covered by straight streamers extending from all parts of the horizon to the zenith, where they formed a boreal crown of blood-red colour.

Nov. 17, 1910. Heavy Rain in Sicily.—As a result of a violent thunderstorm and 'cloudburst', 18·3 in. of rain fell in 24 hours at Riposto, Sicily. This is the heaviest known fall in a day in Europe.

Nov. 18, 1912. Hurricane in Jamaica.—The western part of Jamaica was devastated by a hurricane of remarkable intensity, especially when the lateness of the season is considered. At Negril Point lighthouse the wind reached 120 miles per hour at 2 A.M., after which the anemometer was destroyed; the storm continued to increase in violence for four hours, but no estimate was made of the highest velocity. The rainfall was very heavy, and, where gullies opened on to the coast, many houses were washed away and a number of lives were lost; elsewhere, as at Savanna-la-Mar, the sea swept over the land and destroyed everything, wrecked ships being stranded in the streets.

Nov. 19, 1421. Storm Flood in North Sea.—An extraordinarily great storm flood in the North Sea affected the coasts of Friesland, Holland, and England. Seventy-two towns were submerged and it is said that 100,000 men were killed. As a result of this storm the Zuyder Zee finally reached its present form.

Nov. 19, 1822. Earthquake in Chile.—By this earthquake the greater part of Valparaiso was ruined, while the shock was felt over an area 1200 miles long from north to south. A large tract of the coast, it is said 100 miles in length, was permanently upraised, at Valparaiso by about 3 feet, at Quintero by about 4 feet. Three weeks later, the old bed of the sea was still bare, with beds of oysters and other shell-fish adhering to the rocks. An old wreck near Quintero that before the earthquake could not be reached was afterwards accessible from the land.

Nov. 19, 1824. Inundation at St. Petersburg.—As a result of a violent westerly wind which heaped up the waters of the Baltic in the Gulf of Finland and impeded the flow of the Neva, St. Petersburg suffered from the greatest inundation since the foundation of the city. The waters of the Neva rose 13 ft. 7 in. above the ordinary level, and the whole city except some suburbs was submerged. The damage was aggravated by a frost which followed the flood.

Nov. 19, 1928. Cloud formed by Aeroplane.—A Swiss aviator reached a height of about 33,000 feet in clear air near a thin sheet of cirrus cloud. A definite streak of cirrus formed behind the aeroplane, and persisted from 3.45 P.M. until 4.15 P.M., gradually being distorted by the wind. It was successfully photographed from the ground.

Nov. 19, 1928. High Solar Prominence.—An eruptive solar prominence, the highest on record, was observed at the Kodaikanal Solar Observatory, India, to reach the height of 20′·9 (that is, two-thirds of the sun's diameter or about 570,000 miles) above the sun's chromosphere, when cloud intervened. The brightness of the prominence at so great a height was also remarkable. Comparison of several spectroheliograms taken in calcium light gave the greatest outward velocity of the prominence as nearly 145 miles a second.

Nov. 20, 1242. Floods in England.—Miss Ormerod quotes that "there happened a marvellous tempest of thunder and lightning, and therewith followed such an exceeding rain (which continued many days together) that rivers rose on marvellous heights, and the Thames itself, which seldom riseth or is increased by land floods, passing over the banks, drowned all the country for the space of six miles about Lambeth, so that none might get into Westminster Hall, except they were set on horseback".

Societies and Academies.

LONDON.

Royal Society, Nov. 6.—**W. A. Bone** and **S. G. Hill**: The slow combustion of ethane. The slow interaction of ethane and oxygen in various proportions at 290°-320° C. and pressures between 420 mm. and 780 mm. involves essentially 'chain reactions', preceded by well marked 'induction periods'. Addition of small amounts of third bodies may materially shorten the induction period. The subsequent oxidation then proceeds in a manner consistent with the 'hydroxylation' theory, at a rate dependent chiefly upon the ethane concentration.—**A. Fage** and **W. H. Falkner**: An experimental determination of the intensity of friction on the surface of an aerofoil. Using small surface tubes of the Stanton type, measurements of velocity were taken at distances of 0·002-0·003 in. from the surface, from which the velocity gradients at the surface and the intensities of the surface friction were determined. On each surface the frictional intensity had two maxima, the first associated with laminar flow, and the second with turbulent flow in the boundary layer.—**A. M. Tyndall** and **C. F. Powell**: The mobility of ions in pure gas. In experiments with nitrogen the negative carriers were in every case electrons, but the results with positive ions were variable. Small traces of impurity have a great effect on the mobility of the positive ions. The results are in accordance with the view that a positive ion can capture an electron from a neutral molecule of lower ionisation potential, with a consequent change in the nature of the ion. At pressures of 100 mm. or more, the amount of foreign impurity must be reduced to the order of one part in a million. At present no significance can be attached to any of the values recorded in the literature.—**S. Chapman** and **A. T. Price**: The electric and magnetic state of the interior of the earth. A detailed examination of the currents induced within the earth by the primary outer fields of the daily magnetic variations, and of the storm-time variations of the earth's field during magnetic storms. The induction is supposed to occur within a uniform conducting core of which the upper surface is at a depth of about 250 km. below the earth's surface; evidence is found for a rapid rate of downward increase of electrical conductivity in the layer below 250 km.—**R. H. Fowler**: Speculations concerning the α-, β- and γ-rays of Ra B, C, C″, I. Replacing the ideal Hertzian oscillator in the nucleus used in Miss Swirles's theory by an actual model nuclear quantum-mechanical system, interacting by Coulomb forces with the electrons of the outer atom, shows that there is no likelihood of any serious modification of her calculations so long as the dipole moment of the two nuclear states concerned in the emission of any γ-ray does not vanish. When it does vanish and the nucleus can, practically speaking, not *radiate* this frequency at all, the more correct interaction integral of the revised theory still does not vanish, but survives, operating ejections of the K-(etc.) electron as a β-particle by collision with the nuclear particle, when the K-electron actually enters the nucleus.—**R. Fort** and **C. N. Hinshelwood**: Further investigation on the kinetics of gaseous oxidation reactions. The substances studied were methane, methyl alcohol, and formaldehyde, the two latter being intermediate products in the oxidation of the former. These characteristics of the reactions are best explained by assuming a 'chain' mechanism, which does not seem to depend upon any particular chemical configuration of the reacting molecules, so long as the necessary energy is available. The part played by the walls of the containing vessel depends not only on the dimensions of the vessel but also on the nature of the surface. It seems probable that the adsorbed layer of oxygen may play an important part in breaking the chains which reach the wall.—**C. N. Hinshelwood** and **K. Clusius**: The displacement by ultra-violet light of the explosive limit in a chain reaction. Mixtures of phosphine and oxygen at ordinary temperatures react negligibly slowly except between two sharply defined limits of pressure. In this region explosion occurs, the passage from the slow reaction to explosion being abrupt. Ultra-violet light of wave-length 2500-2800 A. diminishes the lower pressure limit. This effect is shown to be due to the production from the phosphine of a minute amount of an active substance, which does not decay immediately when the illumination ceases.—**C. D. Ellis** and **G. H. Aston**: The absolute intensities and internal conversion coefficients of the γ-rays of Ra B and Ra C. Measurements of the relative intensities of the natural β-ray groups and those liberated from platinum by the absorption of the γ-rays enable the magnitude of the internal conversion coefficient to be deduced. The results appear to be incompatible with a radiation hypothesis of internal conversion and indicate some other type of coupling between the nucleus and electronic system. The experiments provide a method of measuring the absolute intensities of the stronger γ-rays.—**A. A. Robb**: On a symmetrical analysis of conical order and its relation to time-space theory. The time-space geometry of Minkowski and geometries of larger number of dimensions can be built up on a basis of *before* and *after* relations, and congruence can be defined in purely ordinal terms. The importance of such geometries is disguised by the lack of symmetry in the canonical expression for the square of a linear interval. It is now shown that analytical symmetry may be introduced by taking as the canonical form, not a sum of squares, but a sum of products.—**R. A. Fisher**: The moments of the distribution for normal samples of measures of departure from normality. Two methods are given for discussing the distribution of the ratios of the symmetric functions k_3, k_4, . . . obtained from samples from a normal distribution to the powers of k_2, of the same degree.—**D. H. Bangham** and **N. Fakhoury**: The swelling of charcoal (1). An apparatus is described by which the linear expansion of a charcoal rod can be measured simultaneously with the quantity of adsorbed gas causing it. Expansion seems to result from the pressure exerted by the adsorbed molecules at sharp re-entrant angles in the surface of the adsorbent. The expansion caused by the adsorption of a given quantity of gas increases with the temperature.—**I. Ramakrishna Rao**: The behaviour of water with change of temperature and with addition of electrolytes as studied by the Raman effect. With increasing temperature, the band becomes sharper and shifts towards the short wave-length side, due to changes in the single H_2O, double $(H_2O)_2$, and triple $(H_2O)_3$ molecules. Addition of nitric acid also makes the band narrower. At high concentrations, two sharp, well resolved bands are formed, one attributed to double water molecules and the other to hydrates of the acid.—**E. Rudberg**: Energy losses of electrons in CO and CO_2. Characteristic energy losses suffered by an initially homogeneous beam of electrons sent through the gas at low pressures were determined. The distribution curves for the electrons show several well marked maxima, which are characteristic of the energy levels of the particular kind of molecules under investigation. In the case of carbon monoxide the maxima have been correlated with transitions from the normal state of the molecule to excited states known from the analysis of band spectra belonging to this molecule or to singly ionised

ROYAL SOCIETY OF MEDICINE, at 5.30.—General Meeting.
INSTITUTION OF CIVIL ENGINEERS, at 6.—W. T. Halcrow: The Lochaber Water-Power Scheme.
INSTITUTION OF HEATING AND VENTILATING ENGINEERS (Associate Members and Graduates' Section) (at Borough Polytechnic), at 7.—E. R. Corke: Boiler Efficiencies.
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—G. H. Dannatt: A Londoner's London.
SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section) (at Royal Technical College, Glasgow), at 7.30.—Dr. A. Jaques: Experiences with Blast Furnace Tar.
INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND (at 39 Elmbank Crescent, Glasgow), at 7.30.—J. Holmes: The Turbo Compressor as Supercharger.
SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield), at 7.30.—T. H. Arnold: Technique of the Developments of Microstructures.
PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, at 8.30.—Dr. W. H. Linnell: The Purity, Standards, and Tests of Medicinal Substances (Lecture).
INSTITUTION OF ELECTRICAL ENGINEERS (East Midland Sub-Centre).—G. Rogers: Address.

WEDNESDAY, NOVEMBER 19.

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (at Royal Agricultural Hall), at 11 A.M.—T. P. Francis: Modern Treatment and Disposal of Sewage, especially as affecting Trade Wastes.
ROYAL METEOROLOGICAL SOCIETY, at 5.—J. Edmund Clark, I. D. Margary, R. Marshall, and C. J. P. Cave: Report on the Phenological Observations in the British Isles, December 1928 to November 1929.—A. V. Williamson and K. G. T. Clark: The Variability of the Annual Rainfall of India.—A. Moe: The North Sea as a Link between Climate, Plant Growth, and Migration of Birds, in the British Isles and in Norway. Spring near Yarmouth and at Stavanger.
GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Dr. A. Brammall: A Genetic Study of the Dartmoor Granite, with Analyses by Dr. H. F. Harwood.
ROYAL MICROSCOPICAL SOCIETY (at B.M.A. House, Tavistock Square) at 5.30.—R. J. Bracey: A Universal Tube Length and Cover Glass Correcting Lens System for Use with Microscope Object-Glasses.—Dr. W. E. Cooke and C. F. Hill: Microscopical Studies in Pernicious Anæmia. I. The Hæmoglobiniferous Cell.
INSTITUTION OF CIVIL ENGINEERS (Students' Meeting), at 6.30.—A. T. Black: Address.
INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (jointly with Liverpool Engineering Society) (at the Temple, Liverpool), at 6.30.—J. E. Nelson: Electrification of Runcorn and District.
INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (jointly with Midland Centres of Institutions of Civil and Mechanical Engineers) (at University, Birmingham), at 7.
SOCIETY OF RADIOGRAPHERS (in Reid Knox Hall, 32 Welbeck Street), at 7.—Dr. J. Duncan White: Training in Radiography.
INSTITUTION OF AUTOMOBILE ENGINEERS (North-Eastern Centre) (at Metropole Hotel, Leeds), at 7.15.—A. H. Girling: A New Automobile Braking System.
INSTITUTION OF ELECTRICAL ENGINEERS (Sheffield Sub-Centre) (at Royal Victoria Hotel, Sheffield), at 7.30.—H. Coates and H. J. Norballe: Some Automatic Electric Control Gear Problems.
LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (at Leicester Museum), at 7.30.—G. J. V. Bemrose: Exhibition Evening: Leicestershire Fungi.
ROYAL SOCIETY OF ARTS, at 8.30.—Dr. L. Binyon: Persian Painting.
MEDICAL SOCIETY OF LONDON.—Prof. W. Rothenstein: Painting and the Healing Art (Lloyd Roberts Lecture).

THURSDAY, NOVEMBER 20.

BRITISH WATERWORKS ASSOCIATION (at Agricultural Hall), at 2.30.—R. L. Robinson: The Afforestation of Watersheds.—A. Bobbington: The Land Drainage Act, 1930, in Relation to Rivers Pollution Prevention.—D. F. Worger: The Rural Water Supply Problem.
ROYAL SOCIETY (Special General Meeting), at 4.—At 4.30.—Lord Rayleigh: Iridescent Colours of Birds and Insects.—C. R. Bailey, A. B. D. Cassie, and W. R. Angus: Investigations in the Infra-Red Region of the Spectrum. I., II.—Dr. J. K. Roberts: The Exchange of Energy between Gas Atoms and Solid Surfaces.
LINNEAN SOCIETY OF LONDON, at 5.—R. Gopala Aiyar: An Account of the Development and Breeding Habits of a Brackish-water Polychæt Worm of the genus *Marphysa*.—R. E. Holttum: Malayan Ferns.
ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Dr. L. C. Martin: Colour Vision (1).
INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—G. Bianchi: Some Data concerning Railway Electrification in Italy.
INSTITUTE OF RUBBER INDUSTRY (at Manchester Ltd., Royal Exchange, Manchester), at 7.—G. Martin: The Evaluation of Raw Rubber.
ROYAL AERONAUTICAL SOCIETY (jointly with Institution of Automobile Engineers) (at Royal Society of Arts), at 7.30.—Capt. H. Swan: Recent Developments in Engine Cooling, with Special Reference to Oil Cooling.
NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Tees-Side Branch) (at Cleveland Scientific and Technical Institute, Middlesbrough), at 7.30.—G. T. Edwards: Ship Repairing.
CHEMICAL SOCIETY, at 8.—Prof. J. Read and R. A. Storey: Piperitone. Part XI. Syntheses of Optically Inactive and Active Piperitylamines, Piperitols, and α-phellandrenes.—Prof. J. Read and W. J. Grubb: Researches in the Menthone Series. Part IX. A New Optical Resolution of dl-menthol and of dl-camphor-10 sulphonic Acid.
INSTITUTE OF METALS (London Local Section) (at Royal School of Mines), at 8.—Dr. R. Seligman: Some Non-Ferrous Metals in Chemical Engineering.
ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (Clinical and Laboratory Meeting) (at Hospital for Tropical Diseases, Endsleigh Gardens), at 8.15.—Demonstrations by Sir Aldo Castellani, Sir Thomas Carey Evans and Dr. G. R. Mather Cordiner, Dr. N. H. Fairley, Dr. E. P. Hicks, Col. S. P. James, Dr. G. C. Low, Dr. P. Manson-Bahr, J. F. Marshall, Drs. W. S. Sharpe, H. S. Stannus, Prof. W. Yorke and Dr. D. U. Owen.
BRITISH INSTITUTE OF RADIOLOGY (in Reid-Knox Hall, 32 Welbeck Street), at 8.30.—G. Simon: Diathermy in Pneumonia.—Dr. A. Müller: An X-Ray Generator with a Rotating Water-Cooled Target.

FRIDAY, NOVEMBER 21.

PHYSICAL SOCIETY (at Imperial College of Science and Technology), at 5.—Dr. K. R. Rao: The Spectrum of Doubly-ionised Arsenic.—Dr. E. T. Paris: The Determination of the Acoustical Characteristics of Singly-resonant Hot-wire Microphones.—Dr. H. C. Bowker: The Effect of Temperature on Spark Potential.—Dr. L. F. Bates: The Curie Point.—Demonstration of an Instrument for Compounding Curves, devised by Dr. Haughton.
ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Demonstration of Specimens illustrating the Enlargement of the Prostate, with an Account of the Present State of Knowledge concerning the Etiology of the Condition.
SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (in Muspratt Lecture Theatre, Liverpool University), at 6.—Dr. J. H. Reid: Nicotine.
INSTITUTION OF MECHANICAL ENGINEERS, at 6.—A. Eagle and R. M. Ferguson: The Coefficient of Heat Transfer from Tube to Water in Surface Condensers.
SOCIETY OF DYERS AND COLOURISTS (at Literary and Philosophical Society, Manchester), at 7.—Dr. J. L. Hankey: The Treatment of Aniline Black subsequent to Ageing.
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group) (Informal Meeting), at 7.—W. H. Clark: A Talk on Lantern Slides.
JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7.30.—R. P. H. Graham: Ancient Clocks and Horological Curiosities.
INSTITUTE OF BREWING (at Institution of Electrical Engineers), at 8.15.—Dr. E. S. Beaven: The Culture of Barley for Brewing.
ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section), at 8.30.—Clinical Meeting.
INSTITUTE OF CHEMISTRY (Leeds Area Section) (at Leeds).—Annual General Meeting.
ASSOCIATION OF ECONOMIC BIOLOGISTS.

SATURDAY, NOVEMBER 22.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—H. Plunket Greene: What Schubert did for Song.
BRITISH PSYCHOLOGICAL SOCIETY (at Royal Anthropological Institute), at 3.30.—Extraordinary General Meeting.

PUBLIC LECTURES.

FRIDAY, NOVEMBER 14.

BOROUGH POLYTECHNIC INSTITUTE, at 6.30.—Prof. J. T. MacGregor-Morris: Iron, Nickel, and Highly-Permeable Alloys (Armourers and Brasiers' Company Lectures). (Succeeding Lectures on Nov. 21 and 28.)
ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.15.—J. H. Coste: The Object and Methods of Sewage Treatment, particularly in relation to Inland Towns and Isolated Institutions (Chadwick Lecture).

SATURDAY, NOVEMBER 15.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—H. St. George Gray: The Lake Villages of Somerset.

MONDAY, NOVEMBER 17.

KING'S COLLEGE, LONDON, at 5.30.—Prof. B. P. Haigh: Brittle Fracture in Metals (Armourers' and Brasiers' Company Lectures). (Succeeding Lectures on Nov. 24 and Dec. 1.)

TUESDAY, NOVEMBER 18.

KING'S COLLEGE, LONDON, at 11 A.M.—S. P. Turin: Russian Farming and Agriculture.—At 5.30.—Miss Hilda D. Oakley: The Approach to Reality (1): Through Speculative Thought.
GRESHAM COLLEGE, at 6.—A. R. Hinks: Astronomy in Twelve Chapters: a Summary of Recent Advances. (Succeeding Lectures on Nov. 19, 20, and 21.)
UNIVERSITY COLLEGE, LONDON, at 8.15.—Archbishop of York: The Relations between Philosophy and Religion.

WEDNESDAY, NOVEMBER 19.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Dr. A. Massey: The Prevention of Venereal Disease.
BELFAST MUSEUM AND ART GALLERY, at 8.—Prof. S. P. Mercer: The Romance of a Seed.

THURSDAY, NOVEMBER 20.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Dr. Maude E. Kerslake: Contraceptive Problems of Destitute or Injured Women.
KING'S COLLEGE, LONDON, at 5.15.—Miss Theodora Bosanquet: Auguste Comte and the Positive Philosophers.

FRIDAY, NOVEMBER 21.

TOWN HALL, GATESHEAD, at 7.30.—Dr. M. Ray: The Treatment of Rheumatism (Chadwick Lecture).

SATURDAY, NOVEMBER 22.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—H. Norris: A Survey of Costume from Prehistoric Times to the Elizabethan Era.

SATURDAY, NOVEMBER 22, 1930.

Administration and Research in India.

WHATEVER may be the outcome in the immediate future of the political situation in India, and however it may be affected by the Round Table Conference now sitting in London, it must be remembered that pledges have been given which would result in the exercise of the effective power of government passing in an increasing degree into the hands of the Indian people. This is not the place, even if it were not too late, to enter into argument as to the wisdom of the course that has been adopted in handling Indian affairs; it is the outcome of a policy which was initiated long ago. Enlightened according to the ideas of its day, that policy, nevertheless, failed to appreciate the essential quality of the problem and the conditions which governed its solution.

Under our dominion in India, the administrative, executive, and judicial functions were long solely in the hands of British officials. In the native States with princely rulers, native institutions functioned under the supervision of a British political officer, whose duty it was in case of need to exercise a firm, if tactful, restraining influence over the head of the State. In both cases, control was vested in men trained in the traditions of a great service, men who looked for no material gain from the position they held. Nevertheless, however sympathetically exercised, this control was an alien control, the control of a foreign aristocracy in a conquered land—a condition with which India had been familiar from her earliest historic times.

With the spread of humanitarian and democratic ideals in the nineteenth century, as the Empire expanded, there grew up the conception of a tutelage of the backward races by the white man. To some this meant no more than the preservation of the *Pax Britannica* and an autocratic, if just and benevolent, rule which eliminated the more objectionable features of native custom, but on the whole left it very much where it was. The line of demarcation between the ruler and the ruled was rigorously observed. This was, on the whole, the point of view of Mr. Rudyard Kipling and on broad lines that of the Indian civilian. It did not preclude, and indeed more often than not was accompanied by, a very considerable understanding of native customs and ways of thought, as well as appreciation of their bearing upon the problems of government.

On the other hand, a more widely held, if perhaps less well informed, opinion regarded it as incumbent

upon the white man to raise the status of the native in the scale of civilisation and to train him to a point at which he would be capable of taking a part in the civic life and government of his country. However this aim is to be regarded as an ideal, there can be no two opinions, in the light of experience, as to the means adopted for its attainment. The end in view was to be attained by education—education, that is, on the European model—and a share in representative institutions when the time was ripe and the native had reached the necessary standard of civic responsibility. Hence we find the children of West Africa on their way to this desirable goal reciting in English lists of the capes and rivers of Great Britain!

In India the opportunity was readily grasped by certain classes of the population. Converts—too often solely *ad hoc*—thronged the missionary schools; universities, with curricula framed on English lines, flourished in the various provinces; and Indians were admitted to the Civil Service, the Bar, and the Bench. Gradually representation was introduced in the local and central councils, though tempered by an official British element; "India for the Indians" then became the cry of the political agitator. Home Rule was admitted as a not unreasonable claim.

The peculiar conditions of India have served to disguise the fact, which soon became apparent in dealing with the backward races in our other dependencies, that training upon European lines and through institutions other than those of the people themselves was not suited to their needs. India has a civilisation of her own with a long history behind it. For centuries her culture has attained high development on its own lines in the arts, in literature, in philosophy, and even in a science of its kind. Those of the Indian peoples to whom this culture was native were intellectual, intelligent, and of a singular flexibility of mind. They rapidly assimilated European ideals and methods of education, at least superficially. Their success in law, in medicine, and in some branches of science has been conspicuous both in their own universities and in those of Europe.

The undoubted intellectual ability and adaptability of a certain section of the population and the clamour of agitators who loudly proclaim their hostility to a 'foreign' rule have led many into thinking not only that India is capable of self-government, but also that Indian rule for India will bring peace and an absence of friction in the work of administration. In truth, all that will have been done will be to take the administration from one race and hand it over to another which will not necessarily stand in much closer relation to the population of its jurisdiction than the European. The educated Indian in number represents an exceedingly small percentage of the total population.

The problem of the government of India, the real India, remains unchanged. India is still not one, but many. The lack of unity arising from differences of caste and of race will still be there. The multiplicity of creeds will persist, even though Hinduism may seek by the imposition of an offici[al] pantheon and a common name to mark off i[ts] millions, with their varied beliefs and their loc[al] godlings, from Mohammedan and Parsi. T[he] customs and modes of thought of the peas[ant] population, the wild tribes, the hill men, the noma[ds] and the outcasts may well be as strange to [the] educated Indian as they are to the English civi[lian] fresh from his university. In the recent exami[na]tion for the Indian Civil Service, it would ap[pear] that of the twenty-four successful candidates f[rom] all parts of India, the big majority were Hindu[s]. In a country so vast as India and varying so profoundly in custom and sentiment, in what respect does any one of these when outside his own district, his own race, and his own cree[d] hold the advantage over the English civilian? Differences of caste, of race, of religion, and o[f] culture will still have to be bridged. Sympathy informed by knowledge will be no less an essentia[l] of good and efficient rule.

The mass of the Indian peoples is indifferent t[o] politics; its vital interests are moulded by it[s] religious beliefs. Whatever may be the form of constitution ultimately adopted, in the last resort its efficiency, in view of the peculiar character of Indian conditions, will rest on the relations of the district official with the people under his jurisdiction. It should be unnecessary to labour the point that this depends upon an intimate knowledge of racial character and religious and social customs. Th[is] goes deeper than the broad distinction betw[een] Mohammedan and Hindu, or even the m[any] differences within the latter group.

It has frequently been pointed out that intimate knowledge such as is here held necess[ary] demands intensive study. In the records of [the] Indian census, in the pages of Risley, of Cro[oke] and of the many others who have written on customs and beliefs of the peoples of India, [is] much invaluable material to form the groundw[ork] of such study; but none would deny that in the collection of information bearing on the ethnology

and culture of the Indian peoples much still remains to be done. Whatever change may be brought about in the government of India, this work should be continued.

There can be no question that the Indian university will have an increasingly important charge in the future of the country. With it will lie a great part in educating the administrator and in preparing him for the performance of his function in the government of his country. In the past, it must be admitted, the curricula of the universities have in too great a degree looked to western culture for inspiration. It is true they have not neglected Indian studies; but even in these, specially in earlier days, they have fostered the literary and speculative bias of the native of India, and especially of the native of Bengal. In Indian studies, literary and textual criticism of the Indian classics, philosophy, epigraphy, and the study of literary historical sources have prevailed, to the almost entire exclusion of the problems and conditions of the living India.

In another column we refer to the records of research which have been carried out at the University of Allahabad in recent years. It is there pointed out that great stress is now laid on research in university work. These records indicate the importance which, to-day, is attached to practical work in the natural sciences. On the other hand, in the more specifically Indian side of the work research is almost exclusively literary. Without in any way attempting to minimise the importance of these studies in their bearing upon the history and culture of India, it is permissible to suggest that the universities have a great field for research at their doors. The ethnology, the social anthropology, and the economics of the Indian peoples are matters of vital importance which call for investigation. These are fields to which the natives of India themselves have paid too little attention. Among them it is true there are a few now living who have earned a world-wide reputation by their devotion to anthropological studies; some whose activities have recently turned in this direction it would not be too harsh to say that their theories have been coloured by their political prepossessions. In view of the practical importance of these studies for the future good government of India, the universities would do well to encourage research in the laboratory and in the field. Incidentally, by so doing they would effect a valuable and much-needed contribution to the advancement of anthropological knowledge at large.

Physics and Reality.

The Mysterious Universe. By Sir James Jeans. Pp. ix + 154 + 2 plates. (Cambridge: At the University Press, 1930). 3s. 6d. net.

WHY do we call the universe mysterious? Is it because we know so much about it or so little? The impression left by Sir James Jeans's fascinating book is that it is because the interpretation given appears more fantastic than that which is interpreted. Perhaps the only true mystery is one which is not destroyed by solution.

We exist as the result of an accident to the sun some 2000 million years ago. The stage thus being set, the actors unaccountably appeared and began to interrogate their surroundings. To primitive man simple things were obviously regular, while complex things were apparently capricious. Caprice was more impressive than monotony, and the universe was thought of as anthropomorphic. As time passed, more attentive observation caused a continuous transfer of phenomena from the category of caprice to that of regularity, and the universe was accordingly reinterpreted as a machine. In these last days the machine has broken down, and left a thought-form which is the present physical conception of the ultimate nature of the world and appears to bring us back to caprice, rechristened 'indeterminacy', as the original source of events.

Such is the panorama of scientific history which Sir James Jeans shows us. With a wealth of apt illustration he traces its course, showing in detail how the relativity and quantum theories have led up to the present position, and in conclusion describes his philosophy of the universe as a thought in the mind of a controlling mathematician who has no perceptible emotion, morality, or æsthetic appreciation.

It is admirably done. Despite a few infelicities—the result, apparently, of undue haste—we know of only one book on the same themes which deserves comparison with it. It is difficult to conceive of a more excellent account of the recent developments of physics for the general reader. Most readers, however, will be chiefly interested in the summing-up, and this we find not so admirable. Sir James's review of mankind's successive attitudes towards the universe is too summary to include transition stages, and one of these seems to us, in view of recent developments, to be of the greatest significance. Let us try to indicate it by presenting two different points of view taken in scientific work and thought.

The intellectual habit of the Middle Ages was one of brilliant but unbridled ratiocination based on arbitrary elements of thought. The battle which, in the seventeenth century, was fought and apparently won by the pioneers of modern science was for the exclusion from philosophy of all data which were not directly derived from observation. Galileo and Newton regarded with a not unnatural horror the introduction of hypotheses to correlate observations, and, with as much consistency as is possible to human beings, they preached and practised a philosophy from which hypothetical causes of phenomena were rigorously excluded.

Time passed, and the scientific description of Nature on the new principles went steadily on. But one momentous day something new occurred. The little imp which is always ready to suggest unorthodox devices to the eager investigator whispered in someone's ear: "You want to correlate observations unconfused by arbitrary ideas based on imagination or dead authority? Very good; but the refusal to be dominated by imaginary notions does not require you to abstain from leading them in chains. Why not invent existences—call them 'parameters' if you like, as the mathematicians do—to serve as connecting links between observed phenomena? You may find that one or two such existences will suffice to correlate whole masses of observations which otherwise would remain independent and disconnected, and lead to the discovery of who knows how many new phenomena. You will have sacrificed no principles and betrayed no trust." So it was done. Atoms and an ether were conjured up, and all went as the imp had said, with a success indeed far beyond his boldest insinuations. These conceptions in turn gave place to electrons, protons, photons, probability waves, and what not, as the attack grew more breathless, until to-day the most widely diverse of Nature's secrets, in the heavens or under the sea, are strung together by a few 'quantum numbers'.

It is all very wonderful, but in the meantime what has happened? Just what has occurred so often before: the creature has taken control of the creator. The conceptual scheme of physics is no longer merely an instrument by which observations are correlated; it is the 'reality behind phenomena'—or rather our nearest approach to the reality, for the scheme is not yet complete. So that, to reach reality, we have to strip experience of everything that can be seen and felt and enjoyed, until we come down to the inexpressible thought-essence of a hypothetical skeleton.

That, however, is not the worst. Not only must phenomena hide their diminished heads; but, also, they are not allowed even in obscurity to wear their own expression. We observe a determinism in the physical world. The scheme requires that it is a statistical determinism; therefore it is not determinism. We observe that Nature proceeds by laws. The scheme requires that they are laws of chance; therefore they are not laws. Sir James Jeans does not finally commit himself to this view, but that appears to be only because he is not yet convinced that the behaviour of electrons will not later turn out to be determined. The one thing which emerges clearly from all this, is that, if these ideas are generally adopted, the spoils of victory have passed from Galileo to the Aristotelians. Galileo will not have suffered in vain, it is true, for three centuries have acknowledged his triumph; but the future will belong to his enemies.

Let us make our position clear. We do not wish to exclude hypotheses from science—that would be absurd at this time of day—but they must not be allowed to usurp a position to which they have no title. Their function is to facilitate the correlation of phenomena, not to pose as the sole prophets of God. Science cannot remain bound by restrictions which in the stress of battle the seventeenth century pioneers felt bound to impose. It must move, but it should move forwards and not backwards. We do not want the 'problem picture' in next year's Academy to represent the triumphant Aristotelians raising over the prostrate body of Galileo a banner bearing the inscription, 'The Reality behind phenomena is Pure Thought'. Rather would we see the seed which Galileo planted blossoming into a tree, rich beyond his conception indeed, but still bearing seeds of its own kind.

We can follow Sir James Jeans through the maze of present-day physics, and do so gladly, charmed by the facile mastery of his exposition, which is so obviously the child of clarity and depth of thought. But when he attempts to discuss the status of physical conceptions in the world of realities, in an utterance which will be accepted as the autho the voice of science by thousands who seek guidanc matters of philosophy and religion, we feel strong that he is darkening counsel, not by words witho knowledge, but, much more dangerously, by kno ledge without equivalent balance of judgme Physics has much to say at the present time; the is no need for it to speak for other departments o thought and feeling as well.

HERBERT DINGLE.

Lavoisier and the Study of Combustion.

The Eighteenth Century Revolution in Science—The First Phase. By Dr. Andrew Norman Meldrum. Pp. vii + 60. (London, New York and Toronto: Longmans, Green and Co., Ltd., n.d.) 4*s*. 6*d*.

TWENTY-FIVE years ago the author of this book placed chemical teachers and students under a lasting debt by the publication of an essay on "Avogadro and Dalton"—a very careful historical and critical discussion of the standing in chemistry of their hypothesis. Incidentally it was shown that many inaccurate statements on the subject were current at the time in the literature presented to students of chemistry, and a real service was done by putting matters in a clear light.

Dr. Meldrum now reappears, handling in the same thorough way a topic of no less interest to students of chemical history—the work of Lavoisier during the four years 1772–75. These years he calls "the first phase" of the revolution effected by Lavoisier, for they culminated in his realisation of the individuality of oxygen, of its place in the atmosphere, and of the part it plays in processes of calcination and combustion. This is, of course, one of the turning-points of chemical history that no teacher or student can disregard. It also marks a region where there has been strife on matters of credit and conduct, with the importation at times of uncomfortable patriotic fervour, and it is one where there was good occasion for Dr. Meldrum to exercise his powers of elucidation.

The book is based mainly on an intensive study of (1) Lavoisier's Memoirs and Journals (so far as the Journals are accessible through Berthelot's "La Révolution chimique—Lavoisier") and (2) Bayen's and Priestley's publications. The result is a historical analysis of great interest and value, which gives the feeling that the author, with a mind sternly braced against the access of prejudice, has got down as deeply into the facts as available materials allow. Until the Lavoisier correspondence published, it does not seem likely that we shall more light on the subject.

hat Dr. Meldrum has done is to trace out with ate care the course of Lavoisier's thought, imental work, and publications from the time 2) when he was seized with the idea that was ceforth to dominate him. In the sealed note osited with the Paris Academy of Sciences in November 1773, Lavoisier records his observation of the increase of weight during the combustion of sulphur and phosphorus and the fixation of "an immense quantity of air". He believes that the same will be found to apply generally to processes of combustion and calcination. The discovery he describes as "appearing to me one of the most interesting of those which have been made since the time of Stahl". How Lavoisier had come to begin his experiments Dr. Meldrum has found no indisputable evidence. He does not mention the view, taken by M. Le Chatelier, that Lavoisier was turned to the study of combustion by having competed in 1766 for an Academy prize on the subject of street lighting. Whatever may have been the stimulus, it is clear the Lavoisier conception of the fixation of air as the general cause of the increase of weight in combustion processes flashed into his mind and became a fixed light that no embarrassments from experiment, no errors in deduction, no hostile criticism could dim.

Dr. Meldrum emphasises again and again the importance of recognising this, in following the course of Lavoisier's work and in trying to understand his relation to those who had been working or were working in the same field. Though at a later date, writing to Joseph Black, he describes himself as having been accustomed to regard Black as his master, there seems no reason to doubt that when Lavoisier made his initial discovery he was unaware of the work of Black, and that he shared abundantly the confusion of mind about gases and the gaseous state that then prevailed and was likely to continue as long as phlogiston held the field. Lavoisier comments on the conspicuous neglect in France of the study of gases. His realisation of the possibility of following processes of gas absorption and gas emission during chemical changes by use of the balance now gave him a fixed principle. When he surveyed the existing records he found only "separate pieces of a great chain". "These authors", he says, "have joined only some links of the chain."

In a memorandum, which Dr. Meldrum gives good reason for dating February 1773, Lavoisier enlarged upon his new ideas and the prospects of discovery which they opened. "The Memorandum", says Dr. Meldrum, "has a note of exaltation and even of inspiration. Nothing like it can be found in Hales, Black, Cavendish, Priestley, Scheele." It may be judged from this how far our author is from any tendency to under-estimate Lavoisier.

Following upon these preliminaries, we are taken through the record of Lavoisier's progress as detailed in the "Opuscules physiques et chimiques", published in January 1774. This part of Dr.

Meldrum's book shows him at his best, and it may be strongly commended to those who are concerned with the teaching of the history of science, where the chief difficulty is to get students to orient themselves into the conditions of a past age and the state of earlier thought. The mere reading of the old masterpieces, such as are published in the admirable series of the Alembic Club, does not suffice to free the mind from astonishment that great men should have been so slow to find the way that now seems so plain, and to have made mistakes that now appear so gross. Nothing, perhaps fortunately, is likely to make the student believe that the same sort of thing is happening with the great men of to-day; but the discussion of Lavoisier's progress, as elucidated by Dr. Meldrum, is as illuminating an example as could be desired of the historian's art applied to scientific discovery.

The concluding chapter of the book is entitled "The Effective Discovery of Oxygen", and here the author is compelled to enter upon the ground where so much controversy has taken place on matters of conduct. We say that Dr. Meldrum has been 'compelled' to enter upon this ground, because it should be clearly understood that the purpose of the book is not controversial. It is to record the history in detail of the first phase of Lavoisier's work—that on combustion—"which led to a revolution in chemistry and even in science", but this necessarily involves particularities relating to the discovery of oxygen.

Dr. Meldrum says in the preface that he presents fresh conclusions on this subject. This does not seem to be quite the right expression, for his 'conclusions' are in essence those which have been reached by others. What Dr. Meldrum does that is fresh is to exhibit in clear detail the course of thought of Priestley and Lavoisier, and to show exactly how Priestley's work helped Lavoisier out of his difficulties.

It is perhaps too much to expect that the book will not be challenged upon its accuracy in some details, and possibly upon some of its conclusions, but we may surely hope that it will not hurt any susceptibilities. On the contrary, it gives a faithful picture of the times and of the confusion of thought on matters that are to-day the schoolboy's elements of chemical knowledge. It shows how easily both discoveries and mistakes of capital importance could be disregarded by the participants, and how far the true history of the modern doctrine of combustion is from being a simple tale that he who runs may read, or one where he can easily apportion praise or blame.

High Voltage Cables.

(1) *High Voltage Cables: Theory and Practice of their Design and Operation.* By P. Dunsheath. (The Specialists' Series.) Pp. xii+161. (London: Sir Isaac Pitman and Sons, Ltd., 1929.) 10*s*. 6*d*. net.

(2) *High Voltage Cables.* By L. Emanueli. Pp. vii+107+9 plates. (London: Chapman and Hall, Ltd., 1929.) 8*s*. 6*d*. net.

(1) IT seems quite certain that there will be a great demand for high voltage cable for many years to come. In 1924 the consumption of electric energy per head of the population in Great Britain was 100 units. To-day it is more than 150 units, and it is highly probable that by 1940 it will be three times as large. The saturation point is a long way off, and the effect of reducing the number of the supply stations and increasing their size will be to raise continually the pressure of transmission. The demand for high pressure cables, therefore, will go on increasing.

In the book under review, the author first deals with the economic factors that have to be taken into account in high voltage transmission. He next discusses the properties of the insulating materials used in the cables. The question of how the dielectric withstands the electric stress applied to it is still uncertain, but there is no uncertainty about the effect of intersheaths in raising the factor of safety of cables. The chapter on belted, screened, and S.L. cables will be very helpful to students as these types of cable are not yet described in the ordinary text-books. There is also a useful chapter on the current rating of cables and the stability of their dielectrics. The thermal resistivity of a dielectric is defined as the difference of degrees Centigrade required to be maintained between the opposite faces of a centimetre cube of the material so that an amount of heat equivalent to an electrical watt may be transferred continuously across the cube. This definition or something like it is frequently used by engineering physicists, but it seems to us very clumsy and indefinite. Teachers will doubtless improve it. We prefer Fourier's definition. This book is to be commended.

(2) L. Emanueli is the chief engineer of the Pirelli Cable Works in Italy, and he is well known as one of the leading experts on high voltage cables. He has continued the excellent work done by Jona, one of his predecessors. At the Milan Exhibition, so far back as 1906, Jona exhibited cable which had successfully withstood a pressure of 150,000 volts for an hour.

The author in this book points out that the presence of gaseous films and pockets in the dielectric is a frequent cause of breakdown in cables. The presence of highly ionised gas in the small cavities causes distortion of the electrostatic field and a tangential stress is produced above the surfaces of the paper strips. At high stresses gases can migrate through the paper sheets under the action of the ionic bombardment. Thus an ionised path is built up in the direction of the conducting path and breakdown will ultimately result. In the United States there are oil-filled cables operating at 132,000 volts. There is a central duct in the cable which is filled with oil. There are experimental cables also operating at very high pressures in Germany, England, and Italy. In Italy, an oil-filled cable has been operating for a year at 70,000 volts. This book will be of interest to cable engineers.

Our Bookshelf.

Der adsorbierende Bodenkomplex: und die adsorbierten Bodenkationen als Grundlage der genetischen Bodenklassifikation. Von Prof. K. K. Gedroiz. Nach der 2 Auflage des Originals aus dem Russischen übersetzt von H. Kuron. (Sonderausgabe aus den *Kolloidchemischen Beiheften*, herausgegeben von Prof. Dr. Wo. Ostwald.) Pp. viii + 112. (Dresden und Leipzig: Theodor Steinkopff, 1929.) 5 gold marks.

THE translation from Russian into English of a series of pioneering papers by K. K. Gedroiz was in a large measure responsible for focusing attention on the importance of the cation exchange process and the colloidal complex in the interpretation of the properties of soils. A German translation has now appeared of an important paper in which Gedroiz surveys the more recent work, especially in the U.S. Bureau of Soils, the Sudan, and Russia, on the composition and properties of the inorganic colloidal matter of soils, and then attempts to build up a system of soil classification based on the chemical composition of the adsorbing complex. In the present stage of our ignorance of the nature of the soil organic matter, Gedroiz restricts himself to the inorganic colloidal matter. He raises doubts as to the wisdom of the present tendency to identify this colloidal matter with the clay of mechanical analyses, and would prefer to use $0 \cdot 25\mu$ as the upper limit for particle size of colloidal clay instead of 2μ.

After discussing the exchangeable bases responsible for the development of chernozem (or saline) and solontschak and solonetz (or alkaline) soil types, Prof. Gedroiz proposes a method of distinguishing between the acid unsaturated podsol soil and those acid solodi soils derived by breaking down of alkali soils. The so-called amorphous silica soluble in 50 per cent potassium at 100° is greater in the solodi than in the podsol.

Nature Rambles: an Introduction to Country-Lore. By Edward Step. (The "Come-with-Me" Books.) *Winter to Spring.* Pp. vii + 152 + 31 plates. *Spring to Summer.* Pp. viii + 152 + 31 plates. *Summer to Autumn.* Pp. viii + 152 + 31 plates. *Autumn to Winter.* Pp. viii + 152 + 31 plates. (London and New York: Frederick Warne and Co., Ltd., 1930.) 2*s.* 6*d.* net each.

THIS collection of four volumes, divided, as their titles suggest, into the four natural seasons, fulfil one object in making fascinating reading. The author is also to be congratulated on the many splendid illustrations and especially the photographs. Apart from this, the utility of the book is questionable. From an academic point of view, it is practically useless. Besides, a real lover of Nature would prefer to study her along his own lines, rather than along those set out by another. A guide is useful; but this book can scarcely be recommended as such. Placing observations of this type on an ecological basis demands the consideration of causal relationships between habit and habitat. To know the external morphology of a marsh-marigold and to be able to name it on sight is not so useful as to try to find out why it invariably grows in water-logged soils. The author must plead guilty to omitting this important branch of Nature study.

However, the book justifies itself, in that it will take the town-dweller out into the country-side without even leaving his armchair; but he who finds it possible would be well advised to get hold of a good 'flora' and 'fauna' and tramp the country himself.

Old Age, the Major Involution: the Physiology and Pathology of the Aging Process. By Prof. Aldred Scott Warthin. Pp. xvi + 199 (11 plates). (London: Constable and Co., Ltd., 1929.) 15*s.* net.

Two years ago, Dr. Warthin, professor of pathology in the University of Michigan, delivered a lecture before the New York Academy of Medicine on the subject of old age and the aging process. The lecture attracted so much attention that Dr. Warthin was induced to extend it into the form of this most interesting monograph.

The curve of the individual human life, he says, shows an ascending portion, the period of growth or *evolution*; its apex, a relatively short plateau of *maturity*; and the descending portion, the period of retrogression or *involution*. The involution processes, he contends, are essentially physiological in nature, and old age is to be considered as a normal involution and not as a pathological process. He argues his case as a scientific man addressing scientific men. But he does not disguise his hostility to "modern futilities of life-extension of the individual to extreme limits and of possible rejuvenation", and his hope that on such a scientific foundation as he lays there may be built a working philosophy of life.

We have given a bare indication of the contents of a book which is replete with interest, even to the non-medical reader. The descriptions of the successive stages of human life, down to and including senescence and actual old age, are of value, apart from the main purpose of the book.

Letters to the Editor.

The Ether and Relativity.

THE remarkably eloquent Rede Lecture and subsequent small book on "The Mysterious Universe", in which Sir James Jeans seeks to envisage the trend of modern physics in a philosophical direction, will, as is said in the News and Views columns on page 731 of NATURE of Nov. 8, awaken much thought and some disagreement: a result which the conclusion of his preface seems to desire. Certainly he does not scruple to press his conclusions with the utmost boldness wherever they apply, and to display their bearing in many surprising directions. The fact that his contentions about modern physics go far in a direction which specially appeals to me makes me the more critical of what seem their weak points, and a friendly reference may be made to a few places where I join issue with him. He is not an easy person to disagree with, for his knowledge is profound; but one point concerns the meaning and existence of an ether.

As a standard of rest the ether has failed to give any sign, and no experiment made to determine absolute motion has yielded any result except zero. This has been spoken of as a conspiracy, but it may be due to extreme uniformity; it would follow if one and the same perfect substance fulfilled all the functions, while capable of only one speed of transmission, so that differentiation became impossible. I claim that the suggestion is not absence of qualities but perfection. We have had no previous acquaintance with a medium that was "faultily faultless, icily regular, splendidly null", and we are disconcerted; so that (in 1905) we postulate the dictum "Nature is such that it is impossible to determine absolute motion by any experiment whatever", and are tempted to say that any space-filling medium is imaginary.

Sir James Jeans, in his animadversions on the ether of space as a figment of the imagination, quotes with approval a sentence of mine in which I may seem to have given away too much in the effort to secure a kind of general agreement. The sentence quoted runs thus:

"The ether in its various forms of energy dominates modern physics, though many prefer to avoid the term 'ether' because of its nineteenth century associations, and use the term 'space'. The term used does not matter much."

Jeans's comment is:

"Clearly if it is a matter of indifference whether we speak of the ether or of space, of the existence or non-existence of the ether, then even its most ardent devotees cannot claim much objective reality for it."

This use of my admission seems to contain a kind of unfairness. In one of Bernard Shaw's plays, a Roman captain, reasoning with a Christian captive about her prospective martyrdom for not throwing incense on the altar of a heathen god, says, in answer to the plea that she could not sacrifice to false gods:

"Sacrifice then to the true God. What does his name matter? We call him Jupiter. The Greeks call him Zeus. Call him what you will as you drop the incense on the altar flame: He will understand."

That might be quoted as if it were atheism, but it might also be understood as representing a high faith. I wonder that the Christian depicted in the play was able to withstand the argument.

So when I say that for the sake of peace and agreement I am willing to call the ether 'space', or that the name does not matter, I am not implying any disbelief in it, but rather a secure faith which rises above questions of nomenclature. The fact is I am instinctively unwilling or unable to go all the way with Jeans, and to think that nothing exists but mathematical abstractions. The old idea of some kind of a mechanical explanation still has its hold upon me. I have abandoned the old material ether of Lord Kelvin and the nineteenth century, in favour of some hydrodynamic or other perfect mechanism at present unknown. I want a medium with physical properties which can in due time be ascertained and comprehended. I do not suppose that it can be constituted of any kind of matter, or expounded in terms of engineering, and yet I still am unwilling to leave it as a mere abstraction, without properties that can be ascertained; and those properties I at present seek in terms of something physical, responsible for all the activities that have been found existing in space. I am unwilling to shut the door on future discovery, and say that we deal with nothing but abstractions.

Sir James Jeans eloquently contends that the universe is more like a "thought" than anything else, a product of some mind. I have no quarrel whatever with that, but what we know about thought suggests that it requires some physical mechanism to express itself; and that physical though immaterial mechanism is what I seek to understand.

There is one deep-seated contention in which I find myself totally differing from Sir James Jeans, when he says that the theory of relativity not only enables space and time to be unified and treated together in equations and diagrams, but also when he virtually implies that time really *is* one of the dimensions of space. This doubtless was the contention of Minkowsky, who went so far as to say that "space and time separately have vanished into the merest shadows, and only a sort of combination of the two preserves any reality". But it is not in accord with sense or experience to treat time as an actual dimension of space. In the sentence in which Jeans specifically adopts this unification, on page 110, he virtually renders it nugatory by introducing $\sqrt{-1}$ as a necessary factor; having previously taken the velocity of light to be unity. To turn time into space really requires that time shall be multiplied by some velocity and by $\sqrt{-1}$. This is what the four-dimensional mathematicians do, though they did it so long ago that they may have half-forgotten. It is not t, but ict, that is their fourth dimension. With that I have no sort of quarrel. It is equivalent to saying that time is time and not space, that it can be merged with space in an equation, but that it is always kept separate from space, and can be dissected out at the end; for directly the i is removed it reappears as time. The $\sqrt{-1}$ secures it from admixture or confusion.

Jeans treats this unification of time with space as an essential part of the theory of relativity. It seems to me accidental and subsidiary, a practical device rather than a fundamental theory. As to taking the velocity of light as unity, that is another shorthand device, only dangerous if it is forgotten, for neither ingenuity nor habit can really turn a velocity into a pure number. I am willing to grant that an absolute velocity exists, and that space is affected by it; but that very affection makes space something more than geometrical. Space is thereby endowed with a physical quality.

One way of pouring discredit on the ether is to

speak of many ethers; and Jeans goes on to speak of an ether as belonging to each of us, which is indeed nonsense. He elaborates this absurdity on page 104, likening it to the carrying in a shower of rain, not indeed each his own umbrella, but our own rainbow.

All concrete things, in Jeans's philosophy, seem to vanish in a maze of abstractions. Even the waves of which everything is supposed to consist are thought of as abstractions before he has finished, though he has to admit that, as shown on Plate 2, page 42, they are real enough to be photographed. Needless to say, many of his illustrations are helpful; for example, his illustration of the welding together of different dimensions on page 99. Also his parable of the winding river, on page 147, though the moral is that an explorer ought not to be too confident about the direction in which the river is flowing, merely because it happens to be trending in one direction during his particular epoch. The book is full of happy and interesting applications and illustrations, and throughout is absorbingly interesting.

In so far as Jeans exhibits the tendency of modern physics in an idealistic direction, I have naturally no quarrel and welcome his support. Only I do not feel that his contention, that a mathematician alone can hope to understand the universe, is one that will stand scrutiny or substantiate itself. An artist might make another claim. That the Divine Mind can deal with abstractions more fully than any mathematician may be granted, but an Infinite Being has no limitations. His dealing with the abstract does not prevent His also dealing with concrete realities, or cause Him to abstain from attention to the utmost minutiæ. The absence of causation now postulated for the atoms and electrons, because we can only deal with them with any exactness in a statistical manner, is a sign of human limitation, and is not to be thought of as anything ultimate. The 'principle of uncertainty' is not a thing to pride ourselves on, except as a true representation of the present state of our knowledge. The fact that the quantum h enters into it, means that there is more to be discovered. The Divine Artificer does not work with the calculus of probability. The free will of which we have experience is not to be explained as a result of physical indeterminism, though the present appearance of indeterminacy is a sufficient answer to those dogmatists who would wrest the findings of science to make such a thing as freedom impossible. It is useful in so far as it knocks the ground from under their feet, and leaves them without a leg to stand on.

Finally, on the question of the existence of an ether I appeal to the testimony of a greater even than Sir James Jeans. In his book "Sidelights on Relativity", Einstein says, on pages 16 and 17:

"To deny the ether is ultimately to assume that empty space has no physical qualities whatever. . . . Newton might well have called his absolute space 'Ether'."

And on page 23:

"Recapitulating, we may say that according to the general theory of relativity space is endowed with physical qualities; in this sense, therefore, there exists an ether. According to the general theory of relativity space without ether is unthinkable."

I entirely agree; whenever we leave mathematical abstractions and attempt to contemplate what is really happening, or happening in a physical sense, the discontinuity of matter must be supplemented by a continuous medium full of energy; which medium, I venture to say, is used as the instrument for causing and guiding all perceptible motions.

OLIVER LODGE.

Normanton House, Lake, Salisbury Plain,
Nov. 10.

Genetics, Mathematics, and Natural Selection.

IT is a great honour to an author to have his book reviewed by the principal surviving advocate of the theories he has attacked. The only drawback to this honour is that the faculty of criticism, especially perhaps of impartial criticism, is very unequally developed in mankind, and, with the most honourable intentions, many misstatements or other slighter misrepresentations are likely to result. I should like to confine my remarks to six of these from the review of my book in NATURE of Oct. 18, which, I am sure, Prof. R. C. Punnett will be as glad as I to see decently buried. They can all be easily verified.

(a) "Dr. Fisher deplores the cleavage between the mathematical and the biological mind".

Actually, I deny the existence of such a cleavage; and that although I am well aware that a few of the more conservative geneticists are feeling sore, and even anxious, about the increasing tendency of biologists to use mathematical methods. Such a feeling may be worthy of biological study, but is assuredly not characteristic of the biological mind, as I have exceptionally good reason for knowing.

(b) "the selective value of the mutation is regarded as in arithmetic proportion to its size, a view to which we fancy few biologists will be willing to subscribe."

My book is guiltless of any such assertion as this about mutations; on the contrary, an entire section (pp. 38-41) is given to examining why it is that, with highly adapted organs and organisms, the average selective advantage of mutations *falls off* with increasing magnitude.

As the author of the 'presence and absence hypothesis', it is natural that Prof. Punnett should dislike the theory of dominance I put forward; and as a poultry geneticist, that he should give undue prominence to the guess which, in the light of that theory, I have made as to the dominant genes found in the domesticated races of fowls. Such intensive interest might, however, have been accompanied by a higher level of accuracy:

(c) "Hence we must suppose that the mutational changes which give rise to dominant characteristics in domestic poultry show little or no influence in the wild form, that is, are either recessive or nearly so."

This may be Prof. Punnett's own inference; if it is intended to represent mine, as its context suggests, I must quote (p. 61) "not either completely dominant or completely recessive".

(d) "The mutant gene for crest must be regarded as having been brought in by the wild cock, in which it behaved as recessive to its uncrested allelomorph."

Nothing resembling this strange theory has been put forward by me.

Readers who remember the argument of Prof. Punnett's "Mimicry in Butterflies" will be interested in the following:

(e) "he seems rather uncomfortable about the way he disposes of Marshall, stating that we 'can neither assert that the Müllerian principle will work, nor that it will fail'."

Prof. Punnett must have been reading hurriedly; he has left out "so far as these arguments carry us", from before the passage quoted (p. 153). The arguments in question are Marshall's, and Dixey's answer, which effectively neutralised Marshall's argument.

(f) "He strives hard, we think unsuccessfully, to get round it [Marshall's argument]; for in doing so he has to postulate an intermediate state enjoying the advantages of both."

This is one of the postulates of which I say (p. 153) "both are clearly extreme assumptions; neither can be true generally". Naturally, this postulate does

Passage of an Electric Discharge through Gases.

WHEN an electric glow discharge is passed through a tube containing air at pressures of the order of 5 cm. of mercury, the tube lying in one of the two beams in a Jamin's refractometric arrangement, there is a sudden shift of the interference fringes indicating a decrease of the refractive index of air due to the passage of the discharge. A preliminary announcement of the effect has already been made in the columns of NATURE (vol. 120, p. 880), and a detailed account of the experiments published in the *Indian Journal of Physics*, vol. 3, pp. 425-430.

When the discharge is stopped there is an equally sudden shift of fringes in the opposite direction and of the same extent as before, showing that the air has returned to its original state. The switching on of the discharge also causes a sudden increase in the pressure of the tube as indicated by an attached manometer, the pressure getting back to its original value as soon as the discharge is stopped. There is an exact proportionality between the fringe shift and the pressure change; and since the fringe shift if greater than one fringe width cannot be quantitatively observed on account of the suddenness of the shift, the phenomenon is better studied by observing the changes in pressure.

The investigation, which was confined to air in the above-mentioned paper, has now been extended to hydrogen, oxygen, nitrogen, carbon dioxide, and chlorine with nearly similar results as with air, namely, that for a fixed value of the applied voltage the amount of shift or the increase in pressure varies with the pressure and becomes a maximum for a certain value of the pressure, which is different for different gases and for different voltages. The effect was found to be greatest in carbon dioxide and least in hydrogen. Experiments were also made using ammonia, sulphur dioxide, and helium. In the first two the results were vitiated by the decomposition of the gas taking place under the action of the discharge, whereas in helium the effect was only just noticeable, scarcely measurable.

In all the above investigations, electrodes were, as usual, sealed into the ends of small side-tubes attached to the experimental tube, so that the electrodes were rather far away from the track of the light beam. By pure accident, however, while experimenting with air, it was found that if the electrodes are long, coming up to the periphery of the discharge tube, or rather the light beam, the fringe shift as well as the pressure change could be observed even at atmospheric pressure and when no visible glow discharge was passing. Previously, when the electrodes were fairly far away from the edge of the beam of light, the fringe shift was a maximum at a pressure of about 5 cm. and was not appreciable at pressures below 4 mm. or above 10 cm. Also, in these experiments, a Tesla discharge had no effect upon the fringes. Under the new conditions, however, when the electrodes extend right up to the periphery of the light beam, both the discharge from the induction coil and the Tesla discharge produce a fringe shift even at atmospheric pressure, the effect with the latter being even greater than that with the former. The effect can thus be demonstrated very easily. It is not even necessary to close the ends of the tube to observe the fringe shift.

It is found that at atmospheric pressure the maximum effect is produced when the ends of the electrodes (which are in the form of long, stout wires or needles) are just at the periphery of the beam of light. If the end is moved into the path of the beam itself or moved away from the beam, the effect diminishes, until when it is only a centimetre away the effect disappears. Evidently, although there is no visible discharge, there is an electric field radiating from the tip of the electrode, and the effect is a maximum when the field embraces the greatest possible volume of the air. The conclusion previously arrived at, that the effect is due to a pushing away of the gas from the neighbourhood of the discharge, now receives ocular proof, for if a little lycopodium powder is dusted into the tube, it is seen that as soon as the field is put on, the lycopodium particles fly away from the electrodes.

Government College, Lahore.

Properties of Dielectrics in Electric Fields.

IN NATURE of Oct. 25 is a communication from Mr. J. Mazur, under the heading of: "Change of the Dielectric Constant of Ethyl Ether with Temperature". This appears a suitable opportunity for raising a question to which I have previously alluded in several communications to the *Phil. Mag.* and in a long letter in NATURE of April 5, 1924. This is that of the nomenclature of the effects found in dielectrics in the wide range of alternating electric fields which have now for many years become increasingly available.

Let us take as a pertinent example the data given for ethyl ether in Mr. Mazur's interesting letter. An early attempt to find the dielectric properties of ether was made by Hopkinson. He first dried the ether by shaking it up with quicklime, and, using an induction coil to create the field, found K was 4·75. Although, however, there was only a small surface of the ether exposed to the atmosphere, within a few minutes K became 4·95 and thereafter observation became impossible, showing how very rapidly minute traces of moisture absorbed from the atmosphere alter the dielectric properties of matter. The above figure for K, and a slightly lower one due to Quincke, have long been quoted in leading tables of dielectric constants. The above experiments were at room temperatures.

Using a field of high frequency, Mr. Mazur finds for different temperatures the following results:

Temp.	K.	
+ 30·0° C.	4·18	
− 105·4° C.	12·39	
− 117·2° C.	2·3	(melting point)
− 118·9° C.	2·0	

Below this K is constant and is very near N^2 for ethyl ether, which is 1·84 for the D line.

In my letter mentioned above, I showed that at a range of frequencies between 8 and 2000, K for celluloid varied from about 12 to 6 at room temperature, and again, by intensive drying, K could be made to vary from about 8 to 4·8 at a low frequency. Similar examples could be multiplied.

Is it not time that physicists found better names for these varying effects than calling them dielectric constants? Faraday's name, 'specific inductive capacity', was less self-contradictory. Early in the century the term 'dielectric coefficients' came into use where the property was found liable to variation, but seems to have dropped out again, possibly as being too cumbersome.

Of late years numerous connexions between dielectric and other properties have been found, and Debye's theory of molecular polarity is receiving increasing experimental support. For these reasons and others, the confusion and inappropriateness of the present nomenclature in this field, and the doubt

as to what exactly the terms used mean, impedes progress. New and convenient terms are needed for expressing the quantities themselves and a general agreement as to the conditions under which the terms should apply. G. L. ADDENBROOKE.

Kensington, W.14, Oct. 30.

Ball Lightning.

PROF. R. W. WOOD's letter in NATURE of Nov. 8, p. 723, is a valuable contribution to our knowledge of this type of lightning. His reference to increasing our knowledge by touching the globe perhaps calls for a word of warning. I think that touching the globe would certainly cause a very severe burn and might possibly also kill the experimenter. Many years ago I saw two globes of lightning. They were reddish yellow in colour and appeared to be rotating. One of them struck a building and burst with a loud report, causing the inhabitants to open the windows and look out to see what had happened, but as there was no trace of anything they looked bewildered. The other drifted away.

Prof. Wood quotes an eye-witness who said that the flashes struck in the water, coming nearer and nearer like advancing shell-fire. This reminds me of a typical case published in the *Phil. Trans.* for 1781, p. 42. It is related how the tenant of a large three-story house facing the sea at Eastbourne was standing and looking through the window at an ominous black cloud. He saw several balls of fire drop successively out of the cloud into the sea. Suddenly he was thrown violently backwards by what he described as a flash of fire. Many people outside the house at that instant saw something which in form and flame they all agreed was like an immense 'sky rocket' strike the house. The tenant's clothes were torn, and pieces of metal he had about him were melted. Every pane of glass in the room was completely smashed. On the ground floor the coachman and a footman were killed, and on the top floor a lady and her maid were rendered insensible. All the bell wires in the house were deflagrated.

I have an impression that globular lightning makes a slight noise as it drifts about. It has been compared to the purring of a cat. A. RUSSELL.

Faraday House, W.C.1.

DURING April 1906, a small storm occurred near Piccadilly Circus. There was one ordinary flash; then some little while later, there was an instantaneous globular flash some distance above the roofs of the buildings. The sound was like that of a shell bursting. I did not see any movement of the globe, although I happened to have been looking in the right direction before it appeared. H. SOUTHORN.

Putney, S.W.15, Nov. 8.

Crystal Structure of the β-Phase of Aluminium-Bronze.

IN the *Memoirs* of the Ryojun College of Engineering, **2**, p. 205; 1929, and **3**, p. 87; 1930, I have confirmed that the eutectoid transformation of aluminium-bronze consists of a stepped change: $\alpha+\delta \rightleftarrows \beta' \rightleftarrows \beta$, and just as it is impossible to suppress, by water-quenching, the change of austenite into martensite in steel, so also it is impossible to suppress completely the change of the β-phase into the β'-phase in aluminium bronze.

In order to determine the crystal structure of the β-phase, it is therefore necessary either to take a powder photogram at high temperature or to retard the change, $\beta \rightarrow \beta'$, on quenching, adding a third element which passes into the solid solution of the β-phase. The latter method was successfully employed by Elis Persson, who suggested that the said phase should have a body centred cubic superlattice. Extrapolating from the lattice constants of the ternary β-phase of copper-aluminium-manganese alloys, he gave $5{\cdot}833 \pm 0{\cdot}005$ A. for the parameter of the binary β-phase, which contains 12·5 per cent of aluminium (cf. *Zeitschrift für Physik*, **57**, p. 115; 1929).

Recently, by constructing a high temperature camera, I have succeeded in taking a powder photogram of a fine rod of the binary alloy, containing 12·5 per cent of aluminium, at about 650° C., and determined that it belongs to a body centred cubic super-lattice, the parameter of which was found to be $5{\cdot}88_7$ A. at this temperature.

On the photogram obtained from the same alloy quenched from 850° C. in water, the spectral lines belonging to the β-phase appeared very weakly, while the intense lines were found to correspond to a hexagonal lattice, which may be regarded as of the β'-phase. The following lattice constants were obtained for these two phases:

β'-phase: $a = 11{\cdot}13$ A., $c = 6{\cdot}342$ A., $c/a = 0{\cdot}5698$.
β-phase: $a = 5{\cdot}835$ A.

Details of the work will be published in the *Memoirs* of Ryojun College of Engineering.

Cage for the Study of Sheep Ticks.

WHILE carrying out work on the life-history of *Malophagus ovinus*, the sheep ked, difficulty was experienced in obtaining an effective cage which could be erected on sheep in the open.

Cages were tried by which pressure of the walls on the body of the sheep was depended upon to provide a close enough fit to confine keds. These were untrustworthy. However, a structure was devised, such that it could be sewn to the skin and lie loosely in the wool, thus preserving normal environmental conditions as closely as possible. This was made by sewing together the short edges of a rectangular piece of muslin 12 in. by 8 in. On one end of the cylinder thus formed the selvage had been retained, so as to afford a suitable hold for the horsehair with which it was attached to the sheep.

Sterilised horse-tail hair was used, enough being collected at one time to provide for several cages, and stored in five per cent phenol.

Preparatory to attaching the cage, wool was clipped away, at the selected site, in the form of a circular track two inches wide leaving a clump of wool about three inches in diameter in the centre.

The cylinder of muslin fitted over the central clump of wool and was hemmed to the skin by means of a double thread of hair. A local anæsthetic (cocaine) was used in attaching one cage, but it was found that if stitching be carried out expeditiously no undue discomfort is caused to the sheep. The wool requires to be washed thoroughly with water to remove cocaine, otherwise death may result to keds.

Closing of the cage was effected simply by drawing the outer edge of the cylinder, bag fashion, and tying with tape. To examine contained keds, the muslin is rolled back in the same manner as a stocking would.

It was found that attachment of such a cage in the region of the hind ribs, half-way down the side, ensured its being covered by the fleece and affording sufficient protection, at the same sime providing conditions favourable to the ked. J. H. TETLEY.

Recent Work on Insulin.

CHEMISTRY.

THE purest preparations of insulin so far obtained show the characteristics of a protein and on hydrolysis yield a number of different amino-acids. It is not possible to state that the activity is related to any particular amino-acid or group of acids, although from analogy with other hormones it might be expected that the activity is mediated by a simpler substance than a protein. More recent work on crystalline insulin, first prepared by Abel, has led to the conclusion that the crystals are truly those of the active substance and do not merely contain it adsorbed upon them.

Abel's method of preparing crystalline insulin is laborious and the yield small: C. R. Harington and D. A. Scott therefore sought for a simpler and better method of preparation (*Biochem. Jour.*, vol. 23, p. 384; 1929). They found that the properties of commercial insulin are profoundly modified by the presence in the solution of an active saponin: the saponin appears to sharpen the isoelectric points of the proteins present. If ammonia is added to an acetic acid solution of insulin containing about 1 per cent saponin, a precipitate forms at about pH 4·5 and can be removed: it contains about 30 per cent of the weight but only 15-20 per cent of the activity. Further addition of ammonia does not produce a precipitate until pH 5·6, although the original insulin is precipitated at about 5·0. This precipitate may be already partly crystalline, and if the process is repeated and followed by recrystallisation at the isoelectric point from a phosphate buffer (without saponin), well-defined and large crystals are obtained. The yield is, however, small, 5-15 per cent of the original material. Saponins vary considerably in their suitability, those with a high hæmolytic power being the more satisfactory. Digitonin may also be used.

These results suggested that the function of the brucine-acetate-pyridine mixture used by Abel is not only that of a delicate buffering system, but also that other physical properties of these substances are involved. The authors found that, for successful results, a definite relationship between the volume of the solution and the liquid-glass interfacial area had to be maintained: success was only obtained with a large volume when it was distributed among a number of small containers, or glass rods were introduced to increase the interfacial area. The crystals are small cubes, which usually stand on one corner, giving a hexagonal outline under a low power, as described by Abel: they are quite uniform and analysis shows them to have about the following percentage composition: carbon 49, hydrogen 7, nitrogen 14, and sulphur 3.

As part of the same research, these crystals and Abel's crystals, two samples of each, one of the latter prepared by Prof. Abel himself, were submitted to thorough physiological assay by Scott, K. Culhane, H. P. Marks, and J. W. Trevan (*ibid.*, p. 397). Scott and Trevan used the mouse convulsion method and Culhane and Marks the rabbit 'cross-over' test of Marks, with slight, and different, modifications of the original method. In the latter, the criterion of activity is the average fall of the bloodsugar over five hours after the injection, expressed as a percentage of the initial value: the test is carried out on two days, the animals being divided into two groups, one of which is given a dose of standard and the other a dose of the preparation under test, on the second day the doses of the two groups being reversed. The total percentage reduction of all the animals on the unknown is then compared with the sum of the reductions on the standard. In all tests the same solution of the international standard insulin powder was used.

The results obtained by all four observers agreed closely: thus for the four preparations, values of 23·6, 22·7, 22·9, and 23·9 units per mgm. were obtained, whilst the results of the four observers were 23·7, 24·8, 24·3, and 20·2 units per mgm. The two lower results were given by the rabbit method, but it is not considered certain that this method really gives slightly lower figures than the mouse method, although such a possibility must be borne in mind. It thus appears that crystalline insulin has about three times the activity of the international standard (8 units per mgm.), and the uniform activity of the four batches strongly suggests that the crystals are those of insulin itself and that the activity is not simply adsorbed on to them. Similar values for crystalline insulin have recently been obtained by Abel and by Freudenberg and Dirscherl.

Insulin is destroyed by proteolytic enzymes, strong caustic alkali, etc.: it is inactivated by formaldehyde and acetic anhydride to a certain extent, and the potency can also be partly restored by treatment with weak mineral acid or weak caustic alkali respectively, as shown by Freudenberg. Jensen and Geiling have confirmed the work on acetyl insulin. In a recent paper, F. H. Carr, K. Culhane, A. T. Fuller, and S. W. F. Underhill (*Biochem. Jour.*, vol. 23, p. 1010; 1929) have described another type of reversible inactivation. When insulin is allowed to stand in solution at room temperature in a mixture of 3 parts of anhydrous ethyl alcohol and 1 part of 3 N hydrochloric acid, it slowly loses its activity, complete inactivation occurring in two days. The change in activity might be from 18·0 to less than 0·1 unit per mgm.; it was accompanied by a shift in the isoelectric point towards the alkaline side of that characteristic of insulin hydrochloride (pH 5·0). Both changes were accelerated by increasing the concentration of the acid or the alcohol, or by raising the temperature. Reactivation was carried out by adding to a 1 per cent solution of the inactive insulin an equal volume of 0·0842 N sodium hydroxide, allowing the mixture to stand at 0° for 17 hours and then acidi-

fying to pH 3·5. Complete recovery of potency was obtained and at the same time the isoelectric point returned to about pH 5·0. It was possible to repeat the process with little loss of potency at the second reactivation. Inactivation was obtained with other alcohols, but secondary alcohols were less efficient than primary, and with tertiary little if any change was produced: other mineral acids could replace hydrochloric, but no change was produced with acetic in the same time. The inactivation was accompanied by the shift in the isoelectric point whenever comparative estimates of the two changes were made, but the effect on potency was not always tested owing to the tedious nature of the animal assays.

Reactivation of some of these inactive compounds was successfully attempted. The isoelectric point cannot be used as an indication of the absolute potency: thus the glycerol and butyl compounds obtained after partial inactivation were found to have different potencies but the same isoelectric points. The authors conclude that the inactive compounds are insulin esters and that the activity of insulin is dependent on the presence of one or more free $-COOH$ groups. Formaldehyde inactivation indicates that an $-NH_2$ group is similarly essential for its activity.

A. Krogh and A. M. Hemmingsen (*Biochem. J.*, vol. 22, p. 1231; 1928) have investigated the destruction of insulin by heat at temperatures between 50° and 117°. At a constant temperature the rate of destruction was found to be proportional at any moment to the concentration. The velocity constant at 117° was about a thousand times greater than that at 50°. From the results obtained it was possible to calculate the rate of destruction at temperatures below 50°. Thus at 20°, 5 per cent of the activity might be expected to be lost in 9 months and 10 per cent in $1\frac{1}{2}$ years; these figures confirm the known stability of insulin solutions at pH 3·5-4·0. In this research the potency tests were carried out on mice or rabbits.

PHYSIOLOGICAL ACTION.

Our knowledge of the intimate action of insulin in the body is still very incomplete: it can only be stated that it is concerned with the metabolism of carbohydrates, more especially with the formation of glycogen in the liver, probably aiding its formation from carbohydrate and inhibiting its formation from non-carbohydrate sources, and with the formation of glycogen in muscle and its subsequent oxidation. It tends to shift the metabolism of the body to a predominantly carbohydrate type, but the actual details of its action depend in part upon the conditions prevailing at the moment. Its inadequate functioning appears to be the sole primary deficiency in diabetes mellitus, since Macleod has found that dogs fed on a diet of raw meat, cane sugar, and raw ancreas will live for years when injections of sulin are regularly given (see *Nineteenth Century*, November 1928, p. 674). The raw pancreas the diet is essential and presumably replaces the external secretion which is also lost after pancreatectomy. In human diabetes this function of the pancreas is usually fairly normal.

One of the lines of investigation of the mechanism of insulin action has been suggested by the observation that glucose cures insulin convulsions. Glucal and dihydroxyacetone, mannose and maltose are also effective, but other sugars and related substances are of little or no value. W. O. Kermack, C. G. Lambie, and R. H. Slater (*Biochem. J.*, vol. 23, p. 410; 1929) have recently shown that hydroxymethylglyoxal not only fails to cure the convulsions, but even exerts a toxic action on mice and rabbits, the symptoms observed resembling those of insulin hypoglycæmia. Again, A. Hynd (*ibid.*, vol. 21, p. 1091; 1927) has found that d-glucosimine, d-glucose-ureide, d-glucosamine hydrochloride, and glutose are ineffective in relieving insulin convulsions in mice: the first compound is also toxic. Hence glucose loses its activity when an NH_2- substitutes an $-OH$ group, when the reducing group is substituted or when a second ring structure is introduced into the molecule.

M. W. Goldblatt (*ibid.*, vol. 23, p. 83; 1929) found that in young rabbits starved for 24 hours small doses of insulin increased the liver glycogen, even when death occurred in convulsions: the muscle glycogen either showed no change or might be decreased when convulsions occurred, but was never entirely absent. Adrenaline relieved or prevented hypoglycæmia and convulsions but did not prevent the rise in liver glycogen due to insulin. Ether anæsthesia, however, both relieved convulsions and prevented the rise in liver glycogen. The author concludes that insulin inhibits glycogenolysis from the liver and that the formation of glycogen is a self-limiting process. Thus, in the fed animal, the liver cannot take up any more sugar so that more is available for utilisation and insulin is less effective in producing hypoglycæmia. This may be contrasted with the view that insulin, by causing the withdrawal of sugar from the blood by the tissues, leads indirectly to glycogenolysis from the liver, the degree of hypoglycæmia depending in part upon the amount of this glycogen available for conversion to sugar. If insulin inhibits glycogenolysis, it must also depress glyconeogenesis, otherwise the glycogen store would continue to increase indefinitely.

S. Soskin (*ibid.*, vol. 23, p. 1385; 1929) investigated by a direct method the possibility of glyconeogenesis occurring from fat as well as from protein, and found that in diabetic dogs, 5 days after withdrawal of food and insulin, the administration of olive or cotton seed oil or butter with a pancreatic lipase extract produced in some experiments an excretion of glucose, over and above that occurring during starvation, which was greater than that obtainable from the glycerol of the fat and the protein simultaneously metabolised: since it presumably could not have come from muscle glycogen (which is not converted into glucose) and the liver glycogen store must have been negligible, fatty acid could have been the

only precursor. However, there were many negative results. It may be that positive results are only obtained when the administration of fat coincides with a temporary increase in the capacity of the liver for glyconeogenesis. It was also noticeable that it was impossible to recover animals with insulin when the experiment had been successful.

Whatever the defect in carbohydrate metabolism in diabetes, it does not apparently concern the actual utilisation of carbohydrate in muscle, in spite of the fact that the rate of withdrawal of sugar from the blood by the tissues is less than usual: thus I. L. Chaikoff and J. J. R. Macleod (*Quart. J. Exp. Physiol.*, vol. 19, p. 291; 1929) found that the response of normal and diabetic dogs to shivering was the same so far as the increased respiratory metabolism and rise in the respiratory quotient were concerned: the protein metabolism was not increased. The quotient fell after ½ hour or so, apparently indicating the formation of carbohydrate from fat.

These short summaries indicate the trend of some of the recent work on insulin and must be taken as covering only a small part of the field: they indicate routes, however, by which the problem of the mechanism of the action of insulin is being approached.

Faraday's Diary.

By THOMAS MARTIN, General Secretary of the Royal Institution.

IT has now been announced that, to mark the forthcoming centenary of the discovery of electromagnetic induction, the Managers of the Royal Institution have resolved to publish a document of exceptional scientific interest and importance, Faraday's "Diary". It may therefore be opportune to give some particulars of the manuscript and of how it came to be written. Scientific men have been aware of its existence for upwards of sixty years, and Bence Jones, Silvanus Thompson, and other writers on the life of Faraday have consulted it for material and have quoted passages from it in their writings; but few of the present generation, to whom the name of Faraday has become a household word, can be fully aware of the nature and extent, the scientific and biographical significance, and the extraordinary interest of these hitherto unpublished papers.

The Managers' Minutes of Nov. 4, 1867, record the bequest by Prof. Faraday to the Royal Institution of six folio volumes of "Experimental Notes", two quarto volumes of similar notes, and some unbound MSS. The actual wording of the bequest (1855) is as follows: "Various philosophical notes of experimental investigation on foolscap paper, paged in series, and partly bound in five volumes, a quarto book of Philosophical Notes, a second larger quarto of similar notes. . . ." At the time of Faraday's death the number of bound volumes had evidently increased to six, and after his death the loose papers were bound up, by order of the Managers, in the same style of binding as that previously used, making folio volumes 7 and 8. These eight folio volumes, together with the two quartos, make up the "Diary" as it exists to-day.

The manuscript extends to more than four thousand pages, covering a period of forty-two years, from 1820 to 1862; and provides, indeed, an almost complete and uninterrupted record of the whole of its author's original experimental work. It is written throughout in his own fine, clear hand, with only occasional lapses into illegibility, and with a very few inclusions of matter written by others, but which is nevertheless related to his work.

A very noticeable characteristic, on turning the pages, is the extremely orderly and methodical way in which the notes were kept, very different from the untidiness of the experimental notes of his predecessor at the Royal Institution, Humphry Davy. Every page of Faraday's "Diary" is dated and every paragraph is numbered. No paper is wasted, every sheet being completely filled with writing, and a very large number of the paragraphs are illustrated, always towards the right-hand margin of the sheet, by freehand sketches in ink. These sketches are roughly drawn, with boldness and economy of line, but many of them are very striking, and give an impression of the apparatus they represent which is entirely adequate for the purpose and far more pleasing than that of the more formal diagrams which accompany the published papers.

In the earlier parts of the "Diary" the numbering of the paragraphs is begun afresh in several places, but from the beginning of folio volume 2 an unbroken sequence is preserved almost to the end, the numbered paragraphs in this series running to over 16,000. The numbers are constantly used for reference to earlier observations. It will be recalled that a similar sequence of numbers runs through the published "Experimental Researches in Electricity", although it should be mentioned that there is no correspondence between the numbers in the "Diary" and those of paragraphs in the published works which describe the same observations. Many, perhaps most, of the pages and separate paragraphs have a pencil line drawn through them, vertically down the middle of the page; and it seems to have been Faraday's practice to cross through in this way matter transferred to or made use of in the preparation of his published papers.

The manuscript is not a diary in the commonly accepted sense. It is not a journal or daily record of events, but a laboratory note-book. It was evidently its author's custom to keep it written up from day to day, as his experiments proceeded.

Its contents are entirely scientific, and although it contains observations made outside the laboratory, these are generally such as have a bearing on his work, as when, for example, during the progress of some experiments on the crispations or undulations caused by vibration on the surface of a liquid, he saw one wet day a brewer's dray rumbling over the cobbles, and noticed that the rainwater collected in the tops of the empty butts was thrown up into heaps very like his crispations.

Most of the work was carried out in his laboratory at the Royal Institution, but from time to time observations elsewhere are described, as when in 1831, in the course of the experiments on induced electric currents, he worked "at Mr. Christie's" with the Gowin Knight magnet of the Royal Society, and later, when he obtained leave of the King and stretched a wire across the Round Pond in Kensington Gardens, with plates in the water, to test some ideas on the possibility of induction by the earth's magnetic field, hoping to observe effects due to the diurnal rotation of the earth.

The entries in the "Diary" describe, with every detail of importance or which may conceivably have any bearing on the result, the apparatus he used and the modifications he made in it from time to time as the experiments proceeded. The effects he expected to find and the observations he actually made were set down with the utmost care and precision, and when the results were not in accordance with his anticipations or appeared to be due to defects in the arrangement of the apparatus, they were nevertheless recorded with the same care as when his best expectations were realised. His extraordinary skill and ingenuity as an experimenter and his perseverance in the face of disappointment are constantly brought home to the reader, who may see how he followed, day after day, the same line of thought and tried first this and then that modification until he was satisfied that the effect he was looking for was or was not there and had exhausted every possibility.

Although the "Diary" is a laboratory book containing particulars and sketches of apparatus and numerical and other data to be transcribed, an aid to memory to be drawn upon in the subsequent preparation of his papers, it is more, much more, than a dry record of facts. From its form and from the care with which it was preserved it is evident that he intended it as a personal record of his work to be kept and referred to. The pages are interspersed with little characteristic passages which serve as windows into the mind of the man, and give to the manuscript a personal character and spontaneity which is absent from his formal papers. His enthusiasm for discovery is evident if only from the extent and variety of the work which is recorded and the persistence with which he works at a problem until experiment has given the answer to his speculations. The originality, the fertility and resourcefulness of his scientific imagination are shown at every turn, in the nature of the problems he sets himself to resolve, the apparatus he devises to test his theories, the points he notes down as worthy of further investigation. Frequently the pages describing a particular research will end in two or three paragraphs in which he poses new problems fresh ideas for research which have been suggested by the work that has gone before.

The pages are full of titbits of laboratory information which throw light on the apparatus and methods of a hundred years ago and will delight the heart of the chemist or physicist of to-day. He insulated the wire of the coils he used in his famous experiments on induced electric currents by interposing twine between the turns of bare wire and separating the layers by strips of calico. Many of his galvanometers he made himself, in the roughest and simplest way. He used the tall glass jar from a "guinea and feather fall" in which to construct a delicate instrument for detecting induced currents. "White of egg", he notes down, "is a very good thing for crispations." He constantly remarks on the wonder and beauty of the effects he obtains. He cannot keep the note of elation from his voice as he underlines and doubly underlines the significant observation in some particularly satisfactory trial, and concludes the description with the words "Very good experiment."

The "Diary" shows, as no other document could do, the gradual unfolding in Faraday's mind of the ideas which led him to his great discoveries. In his series of communications to the Royal Society the matter of his notes was rearranged and expanded, the phrasing made more formal, the descriptions amplified, and the conclusions stated. Reference to many of the unsuccessful attempts was omitted. In the "Diary" the experiments are recorded in the order in which they were actually made. Step by step his progress can be traced. The entries are often brief and without regard for grammar, but it is not difficult to supply the deficiencies and to read between the lines. His thoughts, the movement of his ideas towards the conclusions which he reached and published, may be inferred from the nature of his experiments and the order in which he made them. Probably no other man of science of comparable eminence has left a personal record which is at once so complete and so enlightening, so invaluable a key to the development of a great scientific mind.

The first volume of the manuscript is the smaller of the two quartos, a small green-covered notebook. This was used from September 1820 to December 1823. Faraday's scientific work in these early years (he was twenty-nine years of age in September 1820) was largely chemical and analytical, including the investigation of new compounds of chlorine and carbon, but the volume contains also a few important electrical experiments. The entries for September 1821, for example, record his well-known first experiments on electromagnetic rotations, which led to the misunderstanding with Dr. Wollaston. That for Christmas Day 1821 describes how he first succeeded

in making a wire carrying an electric current rotate under the influence of the earth's magnetic field alone. The second, larger, quarto volume covers the period December 1823 to November 1832. Its contents are also largely chemical, and it contains the record, in May 1825, of the discovery and analysis of bicarburet of hydrogen (benzene).

The second quarto is no more than two thirds filled. Evidently in 1831 Faraday decided to keep his notes on loose sheets of foolscap paper, and from that date onwards (there is some overlapping between the second quarto and the first folio) the "Diary" is on sheets of this character which have been afterwards bound up into volumes. The slim folio volume 1 (February 1831 to June 1832) must be one of the most significant, as it is certainly one of the most interesting scientific manuscripts in existence, for besides some experiments of a miscellaneous character, it contains substantially the record of the work communicated to the Royal Society in the first and second series of the experimental researches in electricity, embodying the discovery of electromagnetic induction. The induction of an electric current in a coil of wire was first successfully obtained, by 'make' and 'break' of the current in an adjacent voltaic circuit, in the famous ring experiment on Aug. 29, 1831.

It is impossible, within the limits of a short article, to give even a summary of the contents of the "Diary". Moreover, one at least of the published volumes will be available, it is hoped, in time for the Faraday Celebrations in September 1931. The notes are carried on from 1831, through the eight folio volumes down to the year 1862, when his powers were failing and his experimental work was at an end. An entry for Mar. 12, 1862, records an experiment which seems to be the last he ever made. He was hoping to obtain an effect of magnetism on light. He failed to find it. It was not the first time he had made this experiment unsuccessfully; but his scientific intuition was not at fault, for others have since found the effect that he was seeking.

Obituary.

Prof. Adolf Engler.

THE death of Heinrich Gustav Adolf Engler, aptly described as the *Altmeister* of systematic botanists, on Oct. 10, in his eighty-seventh year, removes a prominent and striking personality from the botanical world. 'Engler's System' is a phrase familiar to all students of the science, and has been in recent years a subject of warm discussion among those interested in phylogeny and more especially in the 'natural' arrangement of the families of flowering plants. In his student days, Engler came under the influence of the great German systematist Eichler, whose 'System' was a definite attempt to arrange plant-families in series advancing from the more primitive to the more highly specialised; the simplest type of flower was regarded as the earliest and advance implied an increase in number of parts and specialisation of structure. Engler's 'Syllabus', which was a modification of Eichler's system, has been widely used in systematic works and a large proportion of Continental and American 'floras' follows his arrangement. The criterion of primitiveness has been challenged by the school which regards the simplest types of flowers to be reduced and not primitive forms, but in the recently published edition of his 'Syllabus' the veteran botanist vigorously defends his position and suggests that the less-known parts of the African continent may conceal forms which will provide links in support of his theory.

The 'Syllabus' was the basis of arrangement of "Die natürlichen Pflanzenfamilien", a systematic description of the families and genera of plants, initiated by Prof. Prantl and Prof. Engler in 1887 and carried to completion by Engler after Prantl's death early in the progress of the work. The "Pflanzenfamilien" had a wider appeal among botanists than the more erudite and more strictly technical "Genera Plantarum" of Bentham and Hooker. The distribution of the work of compilation among a large number of botanists led to a certain inequality of treatment; but it went far beyond any previous production as a revision of the families and genera of all the groups of the vegetable kingdom. A new and enlarged edition is in course of publication, and of two large volumes issued during the present year under his editorship, Engler was also the author of the greater portion of one and of part of the other, a tribute to his remarkable virility and continued power of work.

A still more ambitious production was the "Pflanzenreich", begun, with Engler as editor, in 1900: a series of complete monographs of the families of flowering plants; a large number of volumes have already appeared.

Engler was in the prime of life when in 1889 he went from the University and Garden of Breslau to Berlin, as professor in the University and Director of the Botanic Garden and Museum. His first scientific post was under Prof. Nägeli in Munich, and his earlier work dates from that University and Botanical Museum and Garden.

One of his early interests was the Saxifrages, on which he published a monograph in 1872. He also contributed (1878–82) monographs of several families to Martius's monumental "Flora Brasiliensis"—which was continuing under Eichler's editorship. Among these was the Aroids, a family Engler made specially his own, and monographed in de Candolle's "Monographia Phanerogamarum", where he elaborated an arrangement of the genera on genetical lines. A developmental study of world floras found expression in his "Versuch einer Entwicklungsgeschichte der Pflanzenwelt seit der Tertiärperiode" (1879–82); and the series of volumes entitled "Die Vegetation der Erde" organised by the late Prof. Oscar Drude and himself in 1895 continues to provide authoritative accounts by experts of the

vegetation of specific areas of the earth's surface. German overseas expansion found in Engler a helpful exponent in organising the botanical exploration of the German spheres of influence in tropical Africa and New Guinea, and in the collation and publication of the results.

In 1881 Engler founded his "Botanische Jahrbücher", a medium for the publication of communications on taxonomy, plant-geography, and plant-history. The increasing importance of the Berlin Garden and Museum under his directorship as a centre of taxonomic work was reflected in the growth of the publication, which still appears regularly.

A conspicuous monument of the abundant energy and organising power of Adolf Engler is the fine Botanic Garden and Museum which he planned at Dahlem, outside Berlin, to replace the former restricted quarters in the city. Here in the open country he was able to develop his ideal, and the Berlin-Dahlem establishment holds a high place among the botanical institutions of the world. Here he continued to work after his retirement, and here, we gather from an appreciation by his pupil and successor, Prof. Ludwig Diels, he found his last resting-place. Few men have equalled his output of botanical work or exercised directly or indirectly a greater influence on the development of the branches of botany to which he devoted sixty years of unremitting and fruitful labour.

A. B. R.

MR. B. B. WOODWARD.

BERNARD BARHAM WOODWARD died on Oct. 27, aged seventy-seven years. He was the only son of Bernard Bolingbroke Woodward, Librarian of the Royal Library, Windsor, and of his second wife, Emma, daughter of Mr. George Barham of Witherdale Hall, Suffolk. He was grandson of Samuel Woodward, the Norwich geologist and archæologist, and nephew of S. P. Woodward, the well-known author of "The Manual of the Mollusca", and of Dr. Henry Woodward, Keeper of Geology in the British Museum (Natural History). He was educated at Merchant Taylors' and University College schools, but his education was interrupted by the early death of his father, and he started life as a clerk in Messrs. Robarts, Lubbock and Co.'s bank.

In 1873 Woodward was appointed Curator to the Geological Society, and was responsible for the removal of the Society's collection from Somerset House to Burlington House and its rearrangement in the new premises. In September 1876 he entered the Printed Book Department of the British Museum, and on Oct. 13, 1881, he was transferred to the new Natural History Museum at South Kensington and was placed in charge of the General Library there, being promoted first-class assistant on Aug. 22, 1887. He retired on July 21, 1920, but was further retained until the beginning of 1922 to carry on the work of the Library Catalogue. He was twice married, his second wife dying in 1904, but leaves no children.

With the scientific environment of his youth it is no wonder Woodward formed a collection of shells when he was ten years of age, and though in early manhood an ardent geologist, serving five years as secretary of the Geologists' Association, all through his long life malacology was his favourite study. Apart from a few popular articles, his first serious contribution was on the Pleistocene Mollusca of the Barnwell gravels in 1888, and from then forward, although hampered with ill-health, he was the author or joint author of a very large number of papers dealing with many aspects of malacology, published in the *Annals and Magazine of Natural History*, the *Journal of the Linnean Society*, the *Quarterly Journal of the Geological Society*, the *Proceedings* of the Zoological and Malacological Societies, the *Essex Naturalist*, *Geological Magazine*, and in many scattered reports on archæological excavations.

Woodward was responsible for the Molluscan portion of the "Zoological Record" from 1893 until 1896, whilst the articles on the non-marine mollusca of the various counties in the Victoria County Histories are from his pen. He was author of "The Life of the Mollusca", 1913, "Catalogue of the British Species of Pisidium", 1913, and joint author of "The Synonymy of the British Non-Marine Mollusca", 1926, the two latter being published by the Trustees of the British Museum. In his official capacity, he was responsible for the formation of the finest natural history library in the world, whilst his "Catalogue of the Books, Manuscripts, Maps and Drawings in the British Museum (Natural History)", five volumes, 1903–15, and supplement, 1922, will always remain as a permanent memorial to his knowledge and painstaking accuracy. This scientific knowledge was always at the service of all students, and he contributed many paragraphs upon malacological papers to the columns of Research Items in NATURE. His death is mourned by a large circle of friends.

DR. LUDWIG MOSER, director of the Institute for Analytical Chemistry at the Technical High School in Vienna, and president of the Verein Oesterreichischer Chemiker, died on Sept. 26 after a motor accident in which his wife was also killed. We learn the following particulars from the *Chemiker-Zeitung*: Born at Vienna in 1879, Moser studied under Vortmann at the Technical High School, and after spending some time in industrial work was appointed assistant to Vortmann. In 1920 Vortmann retired and Moser succeeded to the chair. He reorganised the Institute, which was transferred to new premises, and a department was devoted to micro-chemical analysis. Moser was an untiring investigator, and up to the time of his death more than ninety publications had appeared under his name, many of which related to the rare earths. He also published volumes on the estimation of bismuth and on the preparation of pure gases. At the time of his death he was engaged on the manuscript of a "Lehrbuch der analytischen Chemie", which is not more than half completed.

News and Views.

DR. F. G. BANTING, of Toronto, has been made an honorary fellow of the Royal College of Surgeons of England: he is the first member on whom the College has conferred the honorary fellowship. It will be remembered that about nine years ago Dr. Banting, working with C. H. Best, obtained pancreatic extracts which were active in reducing the symptoms of diabetes in depancreatised dogs: their reinvestigation of the problem of the hormone of the pancreas led directly to the preparation, by J. B. Collip, of purified extracts, suitable for the treatment of human diabetes. The modern treatment of diabetes by insulin dates from this work of Banting's, and although insulin cannot be described as a cure for the disease, yet it has brought immense benefit to numerous patients. In fact, the diabetic, whether child or adult, can face the chances of life to-day almost as well as the non-diabetic. Lord Moynihan, at a meeting of the Council of the Royal College of Surgeons on Nov. 13, when the honour was conferred, pointed out that the discovery of insulin was the first piece of really scientific research in the realm of medicine contributed by the British Dominions. The work was of a physiological character bearing on the practice of surgery, though in itself something entirely outside the surgeon's craft; but its value deserved the recognition of surgeons.

H.R.H. THE PRINCE OF WALES, in honouring the recently incorporated Association of Scientific and Technical Institutions by his presence at dinner in the Guildhall on Nov. 13, once again directed timely attention to the national and imperial significance of a policy of co-ordination and co-operation in the exploitation of material and intellectual resources. Eight years ago His Royal Highness gave support and encouragement to the movement of which the present scheme, which involves the establishment of a central building for the use of the constituent and associated societies, is a logical development. A movement had, he said, been inaugurated which, if steadily supported and wisely guided, may confer benefits upon industry as a whole, both in Great Britain and in the Empire, the extent of which we can only dimly foresee. The time has long passed when any one industry, or any one branch of science, can hope to develop to its full stature without an intimate knowledge of what is going on in other departments of human activity; to say that further research is urgently necessary in almost every branch of industry and science is almost a truism. The Prince congratulated the presidents and councils of the constituent bodies on their foresight and wisdom, expressing his confidence that the outcome is bound to have a favourable effect on the course of wages and of industry. Other speakers at the dinner, at which Sir Ernest Rutherford presided, were Sir John Cadman, Sir Robert Horne, Dr. G. C. Clayton, Sir Auckland Geddes, Sir William Larke, and Mr. Eric Macfadyen, and it was announced that Mr. Robert Mond had made a gift of £10,000 to the Association. The registered office of the Association is Burlington House, Piccadilly, London, W.1, whence a copy of the Memorandum and Articles of Association and information concerning the conditions of individual life-membership may be obtained.

THE Imperial Conference which ended last week is the first over which a Labour Prime Minister of Great Britain has had the privilege to preside. It was not unreasonable to hope, therefore, that this Conference might be distinguished from previous ones by a departure from orthodoxy in its approach to the problems of Imperial co-operation in the development of that large portion of the earth's surface which is comprised by the British Commonwealth of Nations. Yet it must be confessed that the only distinctive feature about this Imperial Conference has been the obvious marked cleavage of opinion on most of the subjects under discussion between the representatives of the Dominions on one hand and those of Great Britain on the other. Little that is tangible has emerged from some weeks of labour. It has been suggested that the comparative failure of the Conference was due to lack of preliminary preparation on the part of Great Britain, and that on no subject on the agenda did Great Britain give a clear lead to the Dominions; and it must be confessed that the criticism appears to be justified. The best and most obvious way to stage Imperial economic discussions is to have prepared beforehand a survey of the methods by which the Imperial Government seeks to achieve economic unity. In this connexion it is disappointing to find how little prominence was given to a proposal, which has authoritative adherents in this and other parts of the Empire, for the creation of an Imperial Secretariat with functions similar to those of the League of Nations Secretariat. Such a secretariat would act as the supreme co-ordination body for the various Imperial bureaux already in existence. It would ensure continuity between the four-yearly Imperial Conferences; and it could, if it were properly supported, present to each Conference an adequate survey of the resources, actual and potential, of the Empire as a whole, without which all talk of the rationalisation of Empire industries is vain.

FROM our point of view, however, the most disappointing feature of the Conference has been the scant attention which appears to have been given to the relation between scientific research and the developments of the material resources of the Empire, and education. It may be that the present Government considers that all that is necessary in connexion with scientific research has already been said or done by previous Conferences. But previous Conferences have scarcely ever considered the influence of Great Britain as a cultural centre, and the means by which the various parts of the Empire can take advantage of the facilities available here for higher education and training. It is a fact perhaps not generally

known that the United States deliberately offers attractions to educationists in British Dominions, while Great Britain has hitherto had little to offer them. The incorporation of a scheme of educational studies in the University of London is now an accomplished fact, and it is, therefore, a pity that no attempt was apparently made to arouse any enthusiasm among the Dominion Premiers for this new link in the chain of Imperial co-operation.

A MOST valuable collection of records and publications on amentia has been presented to the Library of the Royal College of Surgeons of England by Dr. Thomas Brushfield, who was formerly Senior Medical Officer of the Fountain Hospital for Imbeciles at Tooting, under the Metropolitan Asylums Board. The records comprise the detailed histories which Dr. Brushfield compiled of all the children who came under his charge from his appointment in 1914 until his retirement in 1927, with photographs of the children taken on admission and after treatment. The histories are classified by the types of amentia—mongolism, cretinism, microcephaly, and so on—and Dr. Brushfield has preserved elaborate details not only of each child's physical condition and family history, but also of the mental tests employed in each case and of the progress of such as were fit to attend school. All these records are fully indexed, and numerous tables have been drawn up summarising and analysing the material from various aspects. These histories and statistics covering so long a period from the time when the particular study of mentally deficient children was only beginning, are all the more valuable because they have not been continued on any such a scale as was undertaken by Dr. Brushfield. He has presented them to the College Library so that they may be readily accessible for any research worker in this subject, for whom they ought to prove of inestimable value, as there is no comparable collection of similar material available.

BESIDES his first hand records, Dr. Brushfield has also presented his very large collection of papers and cuttings on amentia, gathered from all over the world. These will be kept together in connexion with Dr. Brushfield's own records, and the donor has prepared a full index to them. The papers cover not merely the varieties of amentia, but whatever may possibly bear on the subject, and there are numerous entries in the index under such headings as birth, encephalitis, endocrines, skulls, etc. To complete the usefulness of the collection, Dr. Brushfield has compiled a bibliography of books and articles issued up to the present, of which there is no copy in his collection, on all the subjects covered by his index. He further very generously proposes to keep this bibliography up-to-date and to incorporate into the collection whatever publications he may continue to collect. It is most sincerely to be hoped that there may be workers who will be glad to avail themselves of this carefully prepared material, and that some of them will care to continue the collecting of this special literature, which Dr. Brushfield has so industriously and disinterestedly begun.

THE tsetse flies of Africa appear to be immune from all ordinary methods of control, and the problem is being approached from many aspects. Mr. Harris, who is a Government entomologist working in the Zululand Game Reserve, some years ago came to the conclusion that these insects seek their prey entirely by sight. According to the *Times* of Nov. 14, he gave a demonstration of his recently devised tsetse trap before a number of entomologists and provincial authorities. The trap takes advantage of the fact that the insect is attracted to roughly shaped dummy animals, that it usually attaches itself to the abdomen, and reacts to contrasts of light and shade. It consists of a wooden frame supported on legs and covered with hessian, except at the bottom, and has a gauze panel at the top. Its rough resemblance to an animal appears sufficient to attract the insects in considerable numbers. They settle on the lower part of the trap, and coming within the hessian walls, they are attracted by the light showing through the gauze above, and so enter the trap proper. In the demonstration 18 of these traps were set up, and at the end of a day they were found to contain 1393 flies, of which 912 were females. The fact that such a trap will remain in good order for 18 months, and requires little supervision, suggests that the method is one of sufficient promise to merit its being tested out for a prolonged period.

LEAFLET No. 31 of the Astronomical Society of the Pacific deals with the near approach of Eros, which will be the closest recorded approach to the earth of any planet. The asteroid or minor planet Eros, although normally more remote than Mars, has such a large eccentricity (0·223) that on Jan. 30 next it will approach within 16,000,000 miles of the earth. This will give astronomers the best opportunity they have ever had of measuring the actual distance of a planet, and for several years preparations have been made for the campaign that has now begun. The scale of the solar system is accurately known from mathematical considerations and the observed periods of the planets, so that a knowledge of the distance of any one of these bodies furnishes the distances of all of them. The sun, Venus, and Mars, which are our closest neighbours, are so large and bright that sufficiently accurate measures of their positions are not possible. Eros combines the double advantage of a closer approach than any other body, and of presenting a beautiful stellar image that can be accurately measured on a photograph. During the forthcoming close approach Eros will suffer large perturbations by our system. From these it will be possible to improve our knowledge of the mass both of the earth and of the moon; in fact, the value that will be obtained for the latter will probably be more accurate than any now available. Even at its brightest, Eros is only of the seventh magnitude, so is not visible to the naked eye, although it can easily be seen in a small telescope.

THE elm disease, which is now known to be caused by the fungus, *Graphium ulmi*, first appeared in Holland and Belgium in 1919 and has since spread over most of western Europe. The first definite case recorded in England was at Totteridge, Herts, in the

autumn of 1927, but there is little doubt that the disease was present in the Isle of Wight and probably also in other districts some years prior to that date. From 1928 onwards the Forestry Commissioners have carried out annual surveys, the main findings from which are as follows. The disease has increased steadily each year both as regards rate of spread and intensity of attack and now occurs over the greater part of England. The disease varies greatly in intensity in different districts, but, as a whole, the proportion of trees attacked is quite small and usually less than 5 per cent of the diseased trees have been actually killed. Locally, however, the death-rate may be quite considerable and the disease assume an epidemic character. The rate of attack also is very variable and apparent recovery may take place, for certain trees in which the disease was found in 1928 recovered the following year and are still quite healthy. There appears to be a close connexion between the disease and the elm bark beetle, *Scolytus destructor*. There can be little doubt that the beetle helps to spread the disease by boring infected trees, and the only control measure suggested is that dead elm trees should be removed as promptly as possible, as they provide breeding ground for the bark beetle.

PROF. C. C. J. WEBB'S Hertz Lecture before the British Academy (from the *Proceedings of the British Academy*, vol. 16. London: Oxford University Press, 1930. 1*s*. 6*d*.) is a consideration of the thesis that our knowledge of one another, that is, our recognition of one another as 'selves' or 'persons', is a primary and fundamental form of knowledge, not derivable from or subordinate to our recognition of selfhood in ourselves, or our perception of an external world of things. The lecture falls into two parts. First it is shown that knowledge of others cannot be reduced to an inference from knowledge of self and knowledge of things since all such inferential accounts presuppose the mutual recognition which they are designed to explain. Moreover, it is held that the development both of self-consciousness and of external perception involves the implicit recognition of the distinction between self and others; so that indeed, of these three forms of knowledge, the apprehension of other selves is "in all probability the first to predominate in human experience". Prof. Webb, therefore, is disposed to hold that however intimately all three forms of cognition may be interconnected in the mode and order of their psychological development, each is logically independent, and that no one of them could be derived from any combination of the others.

THE second part of Prof. Webb's lecture draws out the implications of this result especially in the sphere of religious experience. For that experience, though it may arise through any of the three forms of awareness, is always essentially an *intercourse*—a 'social' experience—and may therefore be held to claim the authenticity which has been shown to belong to our recognition of others as 'socii'. Our knowledge of the object of religious experience differs, of course, profoundly from our knowledge of other selves: but Prof. Webb holds—supporting his argument by a comparison of his own view with Prof. Alexander's that these differences are not such as to invalidate the claim here advanced. This bare synopsis indicates only the course of a brilliant lecture. Both parts of it raise difficulties. But suggestion is the business of the lecture form: and this certainly is an admirable example of philosophical thinking and expression.

WE have received from the authorities of the University of Allahabad the first four volumes of "Allahabad University Studies", in which are published the results of research work carried out by members of the various departments of the University in the period 1925–1929. In a prefatory note to the first volume the Vice-Chancellor, Dr. Ganganatha Jha, explains that although research work has been carried on at Allahabad since the seventies of the last century, no attempt has previously been made to place the results on record or to assist in their publication, excepting only in *Indian Thought*, a quarterly journal of Oriental research conducted for a time by the late Dr. Thibaut and himself. With the recent reorganisation of the University on a unitary basis, and in view of the stress now laid on research, the authorities have thought it desirable that members of the University should have a vehicle of publication of their own. This object is eminently praiseworthy, provided the editorial board ensures that the standard maintained is worthy of an institution of university rank.

IT is unfortunately the case that too many educational institutions in outlying parts of the world are prone to issue publications which swell the already overwhelming volume of scientific literature with contributions which are little more than academic exercises. Some of the contributions to the Allahabad volumes are not above criticism in this respect. It is a danger to which the study of English in India is particularly exposed. This must be inevitable in a subject which looks to European rather than Indian culture for its inspiration. On the other hand, Mr. F. J. Fletcher, Principal of Agra College, has written an excellent study of George Bernard Shaw and the place of his writings in the development of modern English society, which is admirable as an analysis and to the Indian student should be an illuminating introduction to certain aspects of English culture. It might, however, have appeared more fittingly in a 'Review'. Although, taking the four volumes as a whole, the various departments of university studies, science, law, philosophy, history, and so forth, are well represented, it is to be noted that while it is as a record of research bearing upon specifically Indian studies that these volumes should have a special interest, these subjects, well represented in the first two volumes, dwindle sadly in numbe in the twc later.

DR. A. P. LAURIE delivered a lecture on photomicrography applied to the work of Rembrandt and his school, at the Royal Academy of Arts, on Nov. 12. Painters such as Rembrandt, who showed their brushwork, had each their own 'hand-writing' with the brush, and can thus be identified. By taking prints,

cutting them up, and placing them one on another, it is possible to make a very close and accurate study of such individual characteristics. Another purpose served is the revelation of weakness in drawing. A magnification of two diameters has been found to be best for Rembrandt and his school. Long experience and special skill are required to obtain photographs which are strictly comparable. It is also necessary to have records from undoubted pictures of the painter's work throughout his career, and also that of members of his school, as a dossier for testing the authenticity of a given picture. Dr. Laurie illustrated Rembrandt's brushwork throughout his career, and the brushwork of his school, by means of a series of lantern slides. While putting forward his opinion with due caution and diffidence, Dr. Laurie said he believes that pictures painted by Carel Fabritius, Flinck, Bol, and possibly Drost, will be found among 'accepted' Rembrandts; that there was a period during Rembrandt's successful time at Amsterdam when he was turning out pictures with the help of his pupils; and that in the first half of the eighteenth century there was a very skilful forger of 'Rembrandts' in his later style. On the other hand, probably no painter of his time has left so many examples as Rembrandt of his personal individual handiwork.

IN *World Power* for October it is pointed out that France is now divided approximately into fifty regions each one of which is surrounded by a triangular or a quadrangular grid of wires at very high pressures, fed by about fifty steam or hydroelectric stations. It is noteworthy that the Paris area is connected only to Caen and the Massif Central. During the War, it was considered advisable to equip Paris with powerful steam stations situated on the Seine and supplemented by a supply from the Massif Central hydroelectric stations. Now that the coal mines in the north have been practically reconstructed, interconnexion will very shortly be made between them and Paris. Future increases in the electric demand will be met by stations near the northern pit-heads. The western regions, and Brittany in particular, have a very poor electric supply. It has been suggested that this might be remedied by the installation of powerful tidal power stations. Another suggestion is to plunge tubes in the sea near Brest which will utilise, in the method proposed by Claude and Boucherot, the temperature difference between surface water and deep water for the generation of electric energy.

ONE of the tallest concrete buildings in the world, A Noite, has been erected in Rio de Janeiro. It has 25 floors and is more than 410 feet in height. The *Westinghouse International Journal* for October calls it a beautiful building in a beautiful city and says that it rivals the famous Sugar Loaf Mountain on the other side of the bay on which Rio is situated. Judging from the photograph shown of this beautiful city, taken from the air, we can scarcely endorse the praise given to the building. For a building of this height, a very elaborate lift installation was a necessity, as a very speedy, efficient, and accurate service has to be maintained. The Westinghouse Electric International Co. has installed its inductor control system, the operation of which is almost entirely mechanical. Stops from outside the lift are registered on a signal panel. When a car approaches within 25 feet of a landing stage where a call has been registered, both an audible and visible signal warns the operator to centre the switch. The lift-car is thus placed under the control of the inductor and automatically slows down, making a level, even stop at the floor with a minimum time lost in deceleration. If the lift-car happens to be fully loaded, the operator simply passes the floor and the call is automatically transferred to the next car. The speed of the cars is 700 feet per minute and each can carry a load of 2500 lb. There are four entrances to the lifts and they have now been working for several months very satisfactorily under heavy traffic conditions.

IN Germany the protection of birds is generally controlled by the Imperial Law of 1888, which details in a schedule, not the birds to be protected, as does British law, but the harmful species which may be destroyed. In Prussia, however, there have existed old codes in the various provinces of the State, often at variance with each other. The announcement is now made from Berlin (by Science Service, of Washington, D.C.) that new and uniform laws for birds and wild flowers have been enacted by Prussia. During the proper open seasons the following birds may now be hunted in Prussia: wild ducks, wild geese, most of the quail family, sandpiper, curlew, snipe, gulls, terns, and pigeons. Thirteen 'outlaw' species are listed which may be killed without restriction at any time, including several hawks, all crows, sparrows, grebes, and herons. All the remainder of the birds are given the benefit of an absolute closed season, although certain, like ospreys and kingfishers, that are given protection generally, may still be shot if necessary for the protection of fish ponds. No more bounties will be paid for the destruction of predaceous birds; bird-lime and traps for catching or injuring birds are prohibited; and birds must not be hunted by the aid of artificial lights. Further, certain wild animals which destroy birds but also prey upon rodents to an even greater extent, notably the wild cat, pine marten, and mink, are given absolute protection. The new list of prohibited plants contains thirty names, mostly of species which have been subjected to destructive collecting by dealers.

SEVERE winters in Great Britain are not common, but when they do come, havoc usually results in many domestic water-supply systems. A public service has therefore been rendered by the Royal Institute of British Architects by the production of a small pamphlet entitled "Report on Damage to Plumbing Work caused by Frost" (R.I.B.A., 9 Conduit Street, W., 1930. 3*d*.) which shows those who have interests in property what should be arranged to prevent damage. Initiated by the Science Committee of the R.I.B.A., the suggestions are the result of the deliberations of a conference which included representatives from the Ministry of Health, the L.C.C., and a number of other bodies representing various interests. These

suggestions include plumbing matters dealing with the location of pipes and provision of stop-cocks, instructions to householders upon precautions to prevent freezing in water systems, and hints upon hot-water boilers in connexion with frost stoppages.

THE next annual Congress of the Royal Institute of Public Health will be held in the City of Frankfurt-on-Main on May 19–24 (Whitsuntide), at the invitation of the German Government, the Municipality, and the University of Frankfurt. The Congress will be presided over by the Marquess of Reading. The inaugural meeting will be held on the morning of May 19, and the scientific work of the Congress will be conducted in English in the following sections: Section I., State medicine and municipal hygiene; Section II., architecture, housing, and town planning; Section III., industrial hygiene: Section IV., women and children and the public health; Section V., tuberculosis; Section VI., pathology, bacteriology, and biochemistry. Educational visits will be paid to the chief places of interest in the city of Frankfurt, including the new housing developments. Some of the chief spas and health resorts of the Rhine and adjacent districts will be visited, including Wiesbaden, Homburg, Nauheim, Kreuznach, and Munster-am-Stein. On May 23, a whole day's visit will be made to Heidelberg. Delegates are being invited from the governments, municipalities, universities, and other public bodies of Great Britain and Ireland and the British Dominions, as well as from continental and foreign countries.

AT the anniversary meeting of the Mineralogical Society, held on Nov. 4, the following officers were elected: *President*, Sir John S. Flett; *Vice-Presidents*, Dr. G. F. Herbert Smith, Prof. C. Gilbert Cullis; *Treasurer*, Mr. F. N. Ashcroft; *General Secretary*, Mr. W. Campbell Smith; *Foreign Secretary*, Dr. J. W. Evans; *Editor of the Journal*, Dr. L. J. Spencer.

SIR VENKATA RAMAN, Palit professor of physics in the University of Calcutta, has been awarded the Nobel Prize for Physics for 1930, for his work on the scattering of light and the discovery of the Raman effect; and Prof. Hans Fischer, director of the Institute for Organic Chemistry of the Technical High School, Munich, has been awarded the Nobel Prize for Chemistry for 1930.

THE July–September number of *The World's Health* (Vol. 11, No. 3), the organ of the League of Red Cross Societies, is a British Empire number, and contains a history of the Red Cross in Great Britain by Sir Arthur Stanley, a review of Red Cross problems in India by Norah Hill, and a description of the Red Cross clinic for rheumatism in Peto Place, Regent's Park, London, by R. H. P. Orde.

MESSRS. Dulau and Co., Ltd., 32 Old Bond Street, W.1, have just issued Catalogue No. 178 of nearly 1500 second-hand works relating to botany and gardening, many formerly the property of the late Sir George Watt; also Catalogue No. 179 giving the titles of upwards of 1100 works on the subjects of conchology, entomology, geology, ornithology, and general zoology. Both catalogues can be had free upon application to the publishers.

A NEW part—No. 3—of "An Illustrated Catalogue of a Valuable Country Library" has just been published by Messrs. Henry Sotheran, Ltd., 43 Piccadilly, forming No. 820 of "Sotheran's Price Current of Literature". Nearly 3000 works are listed, many of which relate to science and travel. As is usual with the catalogue of which this forms a part, the list is enriched by numerous bibliographic notes which should be of interest and value to collectors and librarians.

THE Bulletin of the Royal Academy of Denmark for 1929–1930 (*Oversigt Kgl. Danske Videnskabernes Selskabs Forhandl.*) contains a complete list of the Academy's publications from its foundation in 1742 to June 1930. This, which is compiled by Asger Lomholt, is arranged under authors and then chronologically. Most of the papers can still be purchased in separate form or in the relatively small parts of the *Oversigt*; the price of each is quoted. The List should therefore be of value to librarians, bibliographers, and booksellers. This part of the *Oversigt* costs 4 kroner (about 4*s*. 6*d*.).

IN the annual report for 1929 of the South African Institute for Medical Research, Johannesburg, recently issued, the director, Sir Spencer Lister, summarises the routine and research work of the Institute. It has been ascertained that in pneumonia and pneumococcic meningitis the strains of the pneumococcus causing these diseases are constantly changing; also, that some of the pneumonic infections occurring among the native mine labourers of the Witwatersrand goldfields seem to be caused primarily by a filterable virus followed by a secondary pneumonic infection. As a result of experimental work, it has been found that nine species of fleas are capable of transmitting plague under laboratory conditions. Dr. Pirie has prepared a pathological report on 600 cases of tuberculosis occurring among native miners, and Dr. des Ligneris has continued his investigations upon cancer, employing Rous's fowl sarcoma for the experimental work.

WE have received the first number of the second volume (March 1930) of the "Index to the Literature of Food Investigation", compiled by A. E. Glennie for the Department of Scientific and Industrial Research (H.M. Stationery Office, 1930). The arrangement is similar to that in the previous numbers, each title being accompanied by a few lines indicating the nature of the work reported and the conclusions reached. The index is preceded by a brief review of noteworthy developments during 1928–29, which is provided with its own bibliography of 79 references. It is proposed to give such a review with the first number of each volume. This summary is useful as a means of keeping in touch with the more important advances in the subject, on which a large number of papers are published annually: thus, upwards of 800 papers are summarised in the present half yearly list. The review deals with the freezing or chilling of meat, the smoking of fish, disease in fruit, corrosion in tins, and some engineering problems; to some of

these subjects reference has already been made in our columns.

DURING the last few years Messrs. Thomas Murby and Co. have become known as publishers of books on geological subjects. Their geological supplies department, or at least the extent of its resources, is perhaps less familiar. A catalogue which they have recently issued can be consulted with profit by teachers and students who may from time to time desire to purchase apparatus and materials for geological work in the field or laboratory. Hammers, collecting bags, map cases, and clinometers are represented in great variety. Collections of rocks, minerals, ores, crystals, thin sections, and fossils are available, specially selected in several cases to illustrate standard text-books on mineralogy, petrology, and palaeontology, together with card trays, cabinets, and slide boxes suitable for the storage or display of specimens. Petrological microscopes by well-known makers are supplied, and all the accessory apparatus required for petrographic methods. Crystal models and structural models of considerable interest for teaching purposes have recently been introduced. Intending purchasers of geological materials and accessories such as those mentioned should consult Messrs. Murby's catalogue.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned :- An assistant lecturer in geography at University College, Nottingham The Registrar, University College, Nottingham (Nov. 26). A lecturer in elementary general chemistry at the National Bakery School, Borough Polytechnic The Principal, Borough Polytechnic, S.E.1 (Nov 28). A resident clinical pathologist at the Manchester Royal Infirmary -The Chairman of the Medical Board, Royal Infirmary, Manchester (Nov. 29). An assistant lecturer in geography at the University College of Hull—The Registrar, University College, Hull (Nov. 30). A whole-time head of the Aristotle Road, Clapham, Junior Commercial and Junior Technical Evening Institute The Education Officer (T 7), The County Hall, Westminster Bridge, S.E.1 (Dec 1). An assistant anatomist in the University of Cape Town The Secretary, Office of the High Commissioner for the Union of South Africa, 72 Strand, W.C.2 (Dec. 17). A full-time pathologist at Napier Hospital, New Zealand The Managing Secretary, Hawkes Bay Hospital Board, Napier, New Zealand (Jan. 10). A male assistant in the sheep department of the Rowett Research Institute Experimental Stock Farm -The Secretary, Rowett Research Institute, Bucksburn, Aberdeen.

Our Astronomical Column.

A Study of Spectroheliograms. An important contribution to the study of the sun's atmosphere by means of spectroheliograms, which record the sun's surface in monochromatic light at different levels from the photosphere to the top of the chromosphere, is given by L. D'Azambuja in *Annales de l'Observatoire de Paris*, Section d'Astrophysique, à Meudon, Tome 8, Fas. 2. Hitherto most spectroheliograms have been obtained in the hydrogen light ($H\alpha$) and in that of ionised calcium (H and K), though Deslandres in 1894, Hale and Ellerman in 1903, and Fox in 1905 first respectively recorded the sun's surface in the light of other elements. D'Azambuja's present research is concerned chiefly with such elements as magnesium, iron, calcium (neutral), sodium, and strontium, that are characteristic of the lower chromosphere or reversing layer. For this work a powerful spectroheliograph such as that at Meudon is essential, and it was possible to study the changes as the narrow selecting slit was set respectively at the middle and at the edge of the spectral line used. As is well known, there are significant differences (explicable as being mainly due to difference of level in the sun's atmosphere) between spectroheliograms taken in the light which comes from the narrow central portion of the $H\alpha$, H, or K lines and those obtained when the edges of the lines are likewise isolated. A comparison of these established differences with those observable in the case of the lines due to lower-lying elements, together with a knowledge of the curves of intensity of the lines, forms the basis of the present discussion.

The memoir also contains results relating to the infra-red lines, $\lambda 8498$ and $\lambda 8542$, of ionised calcium. The possibility of obtaining spectroheliograms with these lines was indicated by C. R. Davidson at Greenwich in 1927, when he measured their intensities relative to those of H and K in the spectrum of the chromosphere. Using hypersensitised neocyanin plates, D'Azambuja has successfully obtained spectroheliograms in these radiations. The memoir, which contains excellent illustrations, whilst presenting new results, is a valuable book of reference to the work of others in this line of solar research.

Identity of a Minor Planet. M. Delporte detected an interesting object at the Uccle Observatory on Sept. 29. He was doubtful whether it was a comet or minor planet, but there is now little or no doubt of its planetary nature. The following orbit is given in *Circular* 364 of the Berlin Recheninstitut by A. Kahrstedt.

M	327°·21	
ω	57·92	1930·0
Ω	1·01	1930·0
i	22·29	1930·0
e	0·2975	
Period	3·538 years	
q	1·631	

It seems very probable that the object is identical with 330 Adalberta, discovered at Heidelberg in 1892, but not seen since that year.

The following observations were then obtained (*Astr. Nach.* 3319):

Heidelberg M.T.	Apparent R.A.	Apparent Decl.
1892 Mar 18ᵈ 11ʰ 23·0ᵐ	11ʰ 57ᵐ 2·90ˢ	0° 6′ 19·6″ N.
„ 20 11 40·0	11 51 28·30	0 8 31·3 S.

It was only by a curious chance that this object received a number and a name. Another planet discovered on 1892 Mar. 19 received the designation 330 Ilmatar; this was afterwards found to be identical with 298 Baptistina, and the planet of Mar. 18 was given the number 330 in order to fill the gap.

If the new object is Adalberta, the period must be about 3·613 years, if 11 revolutions were completed between 1891 and 1931; or 3·31 years if 12 revolutions were completed. Prof. J. Comas Sola announces the discovery at Barcelona of a planet of mag. 10·7 in Pisces, but gives no position: it may be the Delporte object.

Research Items.

Burial Customs of the Akaju, Southern Nigeria. Burial customs of the Akaju tribe, Ogoja division, Southern Nigeria, are described by Mr. C. B. G. Watson in *Man* for November. Guns are fired to announce the death, and for the next two days relatives spend their time collecting food and palm wine. On the third day the corpse is dressed in a new loin-cloth, woollen cap, and shirt or singlet, and is hung in a hammock in the yard of the house. A fire is lit beneath it, the smoke serving in some degree as a preservative. The fire is tended by the wife, or in the case of a woman by women of the same age grade or by her fellow-wives. A man is kept thus for from fifteen days to thirty days according to his wealth, a woman for ten days. On one day a man of the same age grade wearing a special cap dances round the corpse. In the grave, which is oblong with a special recess for the head, the body is placed in a sleeping posture on its side, looking westward if a man, eastward if a woman. Money may be placed in the grave, a hoe is placed on a man's head, a machete may be placed on his chest, and a gun with the trigger removed by his side. No pottery or eating utensils are buried in the grave or broken at its side. After interment, no further ceremonies take place.

Price of Potatoes.—In "Factors Affecting the Price of Potatoes in Great Britain" (University of Cambridge, Department of Agriculture, Farm Economics Branch, Report No. 15), R. L. Cohen attempts to explain the fluctuation in potato prices during the forty-five years for which data are available. Total production tended to fall until 1898, and has since risen, on the average, until the present time. The more recent increases may largely be attributed to higher acreage being put under potatoes on account of the unprofitable nature of other crops, but the interests of neither producer nor consumer would appear to have been served by this heavier production. The analysis of data shows that, generally speaking, imports move in the same direction as prices, and are consequently a result more than a cause of price changes. The chief cause of fluctuation in home production is the variability of yield per acre. Variations in yield are so irregular that farmers cannot contrive to alter their acreage in compensation in order to attempt to stabilise yields, which would have a steadying effect upon prices. It is very desirable that correct information as to the season's production should be spread among British farmers with the view of price adjustment, to prevent foreign producers getting the benefit of high prices at times of shortage, while home growers are still receiving the lower rates of times of plenty. Further benefit would be derived if the fluctuations in growers' prices could be rendered more comparable with those of retail prices, as this would not only tend to stabilise rates from year to year, but also would result in a larger aggregate sum being received by the farmer for his potatoes.

Surface Precipitation Reaction of Living Protoplasm.—In the *Proceedings of the American Philosophical Society*, vol. 69, 1930, L. L. V. Heilbrunn has a very concise statement of his suggested explanation of the astonishing increase in viscosity in living protoplasm that may take place under various conditions, and which is so closely associated with the phenomenon of its 'stimulation' by various external agents. He shows that the films which immediately form at the surface of the extruded protoplasm, when a living cell is burst open in water, only form in the presence of calcium, and that, under certain conditions, similar small films, around vacuoles, form in the protoplasmic mass. This suggests an analogy with the clotting of blood; in the first stage of this process, calcium reacts with blood platelets, thrombin is produced, and this substance can produce clotting even in the absence of calcium. Similarly in the surface precipitation of the protoplasm exuding from a burst egg of the sea urchin, in the first stage an interaction occurs between pigment and calcium and a substance is produced which can bring about the precipitation in the absence of calcium. In the protoplasm, as in the case of the blood, one problem is to explain why this precipitation does not occur until external conditions alter. The reason appears to be, in part, that the calcium inside the living cell is not free, but is bound chemically. Immediately it is freed, on 'stimulation', the precipitation reaction occurs throughout the mass and a great increase in viscosity occurs.

Haploid Plants and Animals.—Prof. R. Ruggles Gates and Miss K. M. Goodwin publish a very valuable review of this subject, with comprehensive bibliography, in the *Journal of Genetics*, vol. 23, 1930. In the plant, the sporophyte generation is occasionally produced with the number of chromosomes characteristic of the sexual cells prior to fertilisation. The authors describe a new case of such a haploid plant in *Œnothera* and pass in review other cases previously described in this genus and in seven other genera of flowering plants. The haploids are smaller than the normal diploids, with smaller cells, and are almost completely sterile. Such plants have appeared (*a*) after crossing, especially with a distantly related species; (*b*) after subjection to cold at the time of fertilisation; and (*c*) (in the tomato) "spontaneously". In the case of animals, many more experimental methods appear to have been employed to bring into being such haploid organisms, but such animals usually either fail to reach maturity or double their chromosomes during development. In certain species of animals, of course, haploid males are the rule, and the authors discuss the theoretical difficulty thus created, as, from the known facts as to the part played by chromosomes in the determination of sex, one set of chromosomes with one '*x*' body might be expected to carry female characters.

Tung Oil.—Tung oil is an essential raw material of present-day varnish manufacture, and its unique properties as a drying oil render it indispensable for certain types of varnish. [It] is also now widely used [a]s an ingredient of certain types of paint media and in the manufacture of electrical insulating varnishes. The demand for tung oil, the possible extension of this demand, and the increasing areas being planted with the seed of *A. Fordii* both in the United States and in the British Dominions, Protectorates, and Colonies has led to the Imperial Institute preparing a memorandum on "The Production of Tung Oil in the Empire", with the co-operation of the Tung Oil Sub-Committee of its Advisory Committee on Oils and Oil Seeds, which is issued by the Empire Marketing Board. The memorandum sums up the history of tung oil under sources of production, its cultivation in the Empire and in the United States, and comments upon the further developments in the Empire. It then deals with methods of cultivation, growth of trees and yield, plantation costs, and utilisation of the nuts. Tabular statements show the exports (amounts and prices) of tung oil from China for the years 1924–28, roughly averaging £3,000,000 per year; the imports into the United States of America for the same years, which reached the £3,000,000 mark in 1929; and the

imports into Great Britain for the same period, the amount in 1929 amounting to a value of £273,350. On the subject of the future outlook, the memorandum states that the increased production will naturally tend to reduce the price, but the reduction should not be so great as to render the cultivation unprofitable. There will always be a demand for tung oil, as it is a raw material essential in some industries, and should always command a higher price than linseed oil.

An Amœba Growing in Cultures of a Yeast. Aldo Castellani has observed the presence of an amœba in glucose-agar cultures of a yeast-like fungus, *Cryptococcus pararoseus* Cast. (*Jour. Trop. Med. and Hyg.*, June 2, July 1, Aug. 1 and 15, 1930). The amœbæ appeared as large, delicate, roundish or oval bodies, which from time to time slowly emit blunt pseudopodia of clear ectoplasm, usually singly. A single round nucleus is present in the protoplasm, which often contains yeast cells. The diameter without pseudopodia varied from $13 \cdot 5\mu$ to $22 \cdot 5\mu$. Movements of translation were observed only in preparations made with Ringer's solution. Cysts occur, 9μ to 12μ in diameter, with a somewhat coarse granular protoplasm and well defined double-contoured membrane. The organism develops only in association with fungi or bacteria: for example, typhoid bacilli, alive or dead. When inoculated into cultures of various bacteria, alive or dead, zones of clearing or lysis were observed. The systematic position of this amœba is discussed by M. Douglas, who concludes that it is an undescribed species belonging to the genus *Hartmannella*, for which he proposes the name *Hartmannella castellanii* (*Jour. Trop. Med. and Hyg.*, Sept. 1).

Reversal of Cilia on the Gill of Mytilus. D. Atkins (*Jour. Mar. Biol. Assoc.*, **16**, 1930) found that nearly one third of the mussels obtained from the Fal Estuary during October and November 1927 presented abnormalities in their gills "doubtless correlated with some factor in the environment". Mussels from other localities were occasionally found with abnormal gills, perhaps in the majority of cases due to the presence of a large female pea-crab (*Pinnotheres pisum*), but the percentage of pea-crabs in the mussels from the Fal was so low (4·8 per cent) that their presence could not account for the large number of abnormal cases observed. The most interesting abnormality is the occurrence of supernumerary food grooves on the surface of the gill, accompanied in most cases by a permanent reversal of the beat of the frontal cilia on that part of the lamella between the main and secondary grooves. Particles drawn on to that part of the gill over which the cilia beat in a reversed direction are carried dorsally into the secondary groove and along it until they reach a filament with normal ciliation, along which they are passed into the main groove. While the author considers that the evidence points to a reversal of the effective beat of the cilia, she has not overlooked the possibility that the epithelium bearing these cilia may be partly formed anew after the production of the secondary groove, and the cilia may from their first formation have acted in the reverse direction.

Absorption of Fats and Lipoids in the Plaice. Mr. B. Dawes (*Jour. Mar. Biol. Ass.*, vol. 17, No. 1, pp. 75-102; 1930) gives an account of his investigations on fat and lipoid absorption in plaice. He found fat to occur in all three types of cell composing the gastric epithelium of the plaice, at the end of a fasting period extending over six or seven days, but to be completely absent from the mucosa of all post-pyloric regions of the alimentary canal at such times. He found a marked increase in the fat content of the superficial epithelium of the stomach after thirty hours and fifty hours of gastric digestion, the stomach thus being shown to be an effective organ of fat absorption. Considerable quantities of fat are present in the duodenal and intestinal epithelia after fat-containing meals have been digested. The rectum also is capable of slight fat absorption. The author suggests that there is a transference of the function of fat absorption from the stomach to the post-pyloric intestine when the frequency with which meals are taken is increased. Globules of true fat are not typically observed in the areolar tissue layer of the alimentary canal, though lipoid granules may occur in abundance. It is concluded that resynthesis of the cleavage products of fat does not occur in this layer.

***Atlantobellerophon*, a New Rhætic Gastropod.** Under the name *Atlantobellerophon zealandicus*, n. gen. et sp., Dr. C. Trechmann describes a *Bellerophon*-like mollusc from the Upper Trias, or Rhætic, of New Zealand (*Trans. N.Z. Inst.*, vol. 61). That its affinities are with *Bellerophon* and its allied forms, here discussed by the author, is evident. That it was presumably a Heteropod mollusc and allied to the modern *Atlanta*, as the author is inclined to infer, is a suggestion which malacologists are scarcely likely to accept without much stronger evidence, seeing how widely apart *Atlanta* and *Bellerophon* have always been ranked in the molluscan phylum.

Raman Effect. A valuable analysis of the literature of the Raman effect published up to the end of June of this year is given by S. Bhagavantam in the September number of the *Indian Journal of Physics*. Some three hundred and fifty references are dealt with—a large increase on the 150 listed by Dr. Ganesan last year in the same journal—and have been grouped under twenty-six heads, the first three of which contain book references and articles of a general character, and the remainder papers on special aspects of the effect. These are followed by an author index and an alphabetical list of the substances which have been studied, and there is a further list of almost a hundred other papers on light scattering which have been published by Indian authors since 1919.

Radioactivity of the Alkali Metals. Investigation of the radioactivity of potassium and rubidium, which is a matter of considerable difficulty when attempted by the usual methods, has been much facilitated by the introduction of the new sensitive particle counter of Geiger and Muller, and the radioactive constants for these elements found in this way by W. Mühlhoff (*Annalen der Physik*, vol. 7, p. 205) are probably as accurate as any yet published. Mühlhoff has confirmed the existence of a hard γ-radiation from potassium, and, from comparative measurements with radium-C and thorium-C, finds for the value of its absorption coefficient in lead, $\mu = 0 \cdot 59$ cm.$^{-1}$: the absorption was followed up to a thickness of more than 8 cm. Measurement of γ radiation from rubidium could not be undertaken for lack of material, but the β-ray activity was found to be 14·2 times that of potassium, and it was confirmed that many of the rubidium β-rays are relatively very slow, their absorption coefficient in aluminium approaching 10^3 cm.$^{-1}$. The half-period for decay of rubidium is given as $4 \cdot 3 \times 10^{11}$ years, and the half-period for potassium $1 \cdot 5 \times 10^{13}$ years, but the latter number must be reduced to $7 \cdot 5 \times 10^{11}$ years if, as is probable, radioactivity is confined to the heavier isotope (41), which is present to the extent of some 5 per cent in ordinary potassium. In any event, the average life of a potassium or rubidium atom is not less than about 100 times that of an atom of uranium.

Band Spectra of Carbon Isotopes.—The July issue of the *Astrophysical Journal* contains an article by A. S. King and R. T. Birge, in which they review the work which has been done up to the present on the isotope bands of carbon. The evidence for the existence of the heavier isotope, of atomic mass 13, is now conclusive, bands due to the molecules $C^{12}C^{13}$, $N^{14}C^{13}$, and $O^{16}C^{13}$ being known to accompany the more intense bands of $C^{12}C^{12}$, $N^{14}C^{12}$, and $O^{16}C^{12}$, and from a study of the isotopic bands of C_2 at 1737 A. ($C^{12}C^{12}$) and 4744·5 A. ($C^{12}C^{13}$) it has now been shown that the mass ratio of the isotopes is 12 to 13, with an accuracy of one part in ten thousand. The most surprising result of this investigation is, however, that the relative intensity of two related isotope bands depends upon the conditions of excitation, making it impossible to estimate their relative abundance with certainty. There is some evidence that the controlling factor may be the effective temperature of the source; when the degree of excitation is low, as in a furnace or in the *N* type stars, the spectra associated with the heavier isotope are prominent. With more intense excitation, such as that of the arc, bands due to the heavier isotope are less strong, the only evidence for the existence of C^{13} from this particular source being a group of lines in the cyanogen band at 3883 A. It is not easy to see how such differences can arise, and after a discussion of the most probable influences (true differences in relative abundance, excitation difference, and dependence on the optical path), the authors practically leave the question open with the remark that the abundance of the isotope of mass 13 and the dependence of its spectrum upon excitation conditions will require much additional evidence. [See in this connexion NATURE, Oct. 25, p. 649.]

The Schütz Law of Enzyme Action.—According to the Schütz law, if x is the quantity decomposed, E the quantity of enzyme, and t the time, then $x/\sqrt{Et} = K$, a constant. In the *Journal of the Faculty of Agriculture*, Hokkaido Imperial University, Sapporo, Japan, vol. 28, part 3, K. Nakajima describes experiments by many previous investigators, and in a critical discussion arrives at the conclusion that the so-called law has no validity in the kinetics of enzymes except in the form $x/\sqrt{E} = K$ for dilute pepsin solutions. He also criticises the Arrhenius law and the Northrop theory, which are held to confirm the Schütz law. A bibliography is provided.

Solubilities of Salts in Ethyl Alcohol.—In the October number of the *Journal of the American Chemical Society*, some experiments on the effect of one salt on the solubility of another without a common ion, ethyl alcohol being the solvent, are described by Seward and Schumb. An increase in solubility (as in other solvents) was found. In agreement with results of previous experimenters, it was found that the solubility curves show considerable deviations from the theoretical curve given by Debye and Hückel's equation, but they are considered to be in qualitative agreement with the extensions of that equation which take account of ionic size.

Reactivity of Coke.—The reactivity of a coke, which measures its capacity for reacting with steam and carbon dioxide, has usually been expressed as the percentage of each gas decomposed under defined conditions. This method of expression does not allow of a quantitative comparison of different cokes, or of the application of values determined under one set of conditions of temperature, gas velocity, etc., to another set of conditions. These shortcomings are avoided by a method described at a meeting of the Society of Chemical Industry, at Leeds on Oct. 28, by Dr. A. Key and Prof. J. W. Cobb, who express reactivity as the reciprocal of the weight of coke required to decompose a definite percentage of gas under specified conditions. It is not necessary to find this weight experimentally, since it is related to the percentage of gas decomposed by a standard weight of coke. This relation has been found and expressed on a reactivity curve which covers all known kinds of coke. It was also shown that the reaction between carbon and carbon dioxide is unimolecular with respect to the gas, while that with steam deviates from this because of complications. The uses of cokes are very largely dependent on their reactivity, and a method of comparison which can be applied generally should prove of great value in the study of carbonised fuels.

Synthesis of Creatine and Alacreatine.—A method worked out by Wheeler and Jamieson in 1908 for the preparation of alkylated guanidines is applied by H. King in the October number of the *Journal of the Chemical Society* to the synthesis of creatine. Sarcosine hydrochloride is treated with alkali and methyl isothiocarbamide hydriodide, with production of a 40 per cent yield of crude creatine. From alanine, the base alacreatine was similarly obtained. The substances were analysed as the crystalline picrates.

Sulphonation of Hydrocarbons.—Although it is generally supposed that saturated hydrocarbons are more or less inert to powerful sulphonating reagents, there have been references in recent technical literature which indicate that this is not the case, and in a paper in the October number of the *Journal of the Chemical Society*, G. N. Burkhardt shows that when an excess of *n*-hexane, cyclohexane, or methylcyclohexane is stirred vigorously with fuming sulphuric acid (35-65 per cent SO_3) at 0°-10° for four to five hours, practically all the sulphuric anhydride is used up. About 1 mol. of sulphur dioxide is formed per mol. of hydrocarbon, and oxidation of some of the hydrogen of the hydrocarbon is an important part of the reaction, perhaps after sulphonation has occurred. The product contained sulphato-sulphonic acids, such as are formed by the action of fuming sulphuric acid on unsaturated compounds; the barium salts, however, were not crystallisable, and special methods were used for the identification of the products of reaction.

Bionomics of Marine Algæ.—In *Bulletin* 67 of the Bernice P. Bishop Museum, "Hawaiian Marine Algæ", Miss Marie C. Neal investigates the seaweeds of the Hawaiian reefs by studying certain small areas throughout the year. The iron stakes which marked out the areas proved very satisfactory for algal growth, also concrete slabs and blocks. Most of the algæ are at their lowest state in December and January, the largest kinds old and dying out. Young plants appear usually in February, when temperatures are slightly higher. Many of the seaweeds have regular life cycles, maturing once, twice, or three times in a year. The succession of plants on an originally clean surface was approximately uniform, diatoms appearing first, then *Ectocarpus*, sometimes *Colpomenia sinuosa* third, or *Padina*, minute green, blue-green, or red algae occurring at the same time. The succession was rather different on a scraped concrete block which was nearer shore and exposed to the air at very low tides, and was thus subjected to some drying and to strong light, the surrounding shallow water being often warmer than the deeper area. The best base for algæ is apparently an immovable one, raised above the sea floor so that sand and stones do not collect on it. Many of the larger seaweeds grew fastest before maturity. The work is illustrated by many text figures.

Colour Vision.*

By Prof. H. E. ROAF

THE physiological problem in colour vision is to determine the varieties of receptors which are present in the retina. An experimental investigation of some aspects of this problem is summarised below.

The best starting point is the result of some investigations on hypochromats (colour blind individuals).[1] The object was to find out if there was any particular region of the spectrum in which they differed from the 'normal'. They were asked to copy geometrical designs in colour, and the copies were compared with the originals in the light of a recombined spectrum from which any specified region could be eliminated. It was found that agreement could be obtained only if the long wave-length end of the spectrum was eliminated. The cases varied in the extent to which the spectrum must be cut down, but it is not certain whether this was due to differences in the degree of the defect or to mere chance; that is, they might make different mistakes in making another copy. At the same time, there is not necessarily any diminution in sensitivity to light (rise in threshold) even to those parts that they fail to discriminate.[2] This is one of the main objections to the Young-Helmholtz hypothesis.

The graph relating wave-length to change in wave-length necessary to produce a visible difference in colour shows two minima (maxima of discriminating power), one about 5800 A. and the other about 4900 A.[3] In hypochromats the former is absent, whilst the latter is as well marked as in 'normals'. This is further evidence that there is a failure to discriminate between the long wave-length and neighbouring parts of the spectrum. It can be said that the hypochromat fails to discriminate what affects the normal as a red element; thus a yellow by loss of red value is matched with green.

To explain the phenomena revealed by the preceding series of experiments, we have to imagine some system whereby the differences between 'red' and 'green' are diminished or abolished without an alteration in the threshold to light from the long wave-length end of the spectrum. On the other hand, the difference between 'green' and 'blue' (neutral region of hypochromats) is as great as with normal individuals.

A type of experiment which ought to show to what extent separate receptors are stimulated by different regions of the spectrum is to shine two lights on the same area of the retina and to measure to what extent they interfere with each other. Quite different results were found for central and peripheral vision.[4]

For central vision, long wave-lengths raise the threshold for all regions of the spectrum, whilst shorter wave-lengths have comparatively little effect on longer ones. Fig. 1 shows an experiment of this sort with three different backgrounds. The ordinates show the multiple of the absolute threshold which is necessary in order to produce a noticeable difference against the background. It is clear that a background of 6214 A. interferes with the visibility of all parts of the spectrum, whilst backgrounds of 5404 A. and 4708 A. have comparatively little effect on the 'red' end of the spectrum. An additional point is that the curves are horizontal down to about 6000 A., which suggests that this part of the spectrum varies only in brightness, and not in colour, with alteration in the wave-length.

With peripheral vision, short wave-lengths raise the threshold for the whole spectrum.

These experiments suggest that there is some common underlying factor in all sensations of light: a fact which is recognised by Hering's assumption that there is a black-white substance and by the spreading out and overlapping of the sensation curves in the Young-Helmholtz hypothesis.

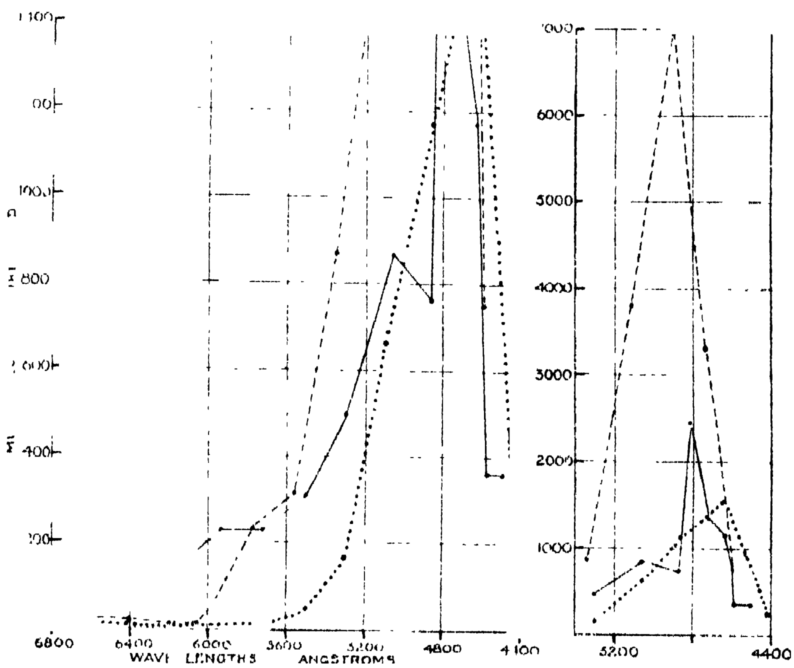

FIG. 1.—Ordinates, multiples of absolute threshold; abscissæ, wave-lengths in A. In order to show the higher values a part of the range is reproduced in one-fifth of the scale. Continuous line, background of 6214 A.; interrupted line, background of 5404 A.; dotted line, background of 4708 A.

It is possible to explain the facts of colour vision on the assumption that there are three sets of receptors (see Fig. 2):

(a) One which is stimulated by the whole of the visible spectrum and this may correspond with the sensation curve of the dark adapted eye;

(b) One which is stimulated by long and medium wave-lengths from the extreme 'red' end to about 4900 A.;

(c) One which is stimulated by long wave-lengths from the extreme 'red' end to about 5800 A.

As shown by the diagrams in Fig. 2, the long wave-length end of the spectrum stimulates all three sets of receptors and the short wave-length end stimulates only one set. That the short wave-length end of the spectrum stimulates a special mechanism is shown by measurements of visual acuity.[5] Wave-lengths less than 4900 A. have a low ratio of intensity to brightness and to visual acuity. Additional evidence that the 'blue' mechanism is stimulated by the whole spectrum is that blue is seen when a pure long wave-length stimulus is looked at slightly eccentrically.[6]

* Substance of a contribution to a joint discussion—"In what Sense can we speak of Primary Colours?"—of Section I (Physiology) and Section J (Psychology) of the British Association at Bristol on Sept. 8.

The three sets of receptors might be explained on the basis of three photochemical substances or that there is one photochemical substance with coloured filters in front of the receptors. The second suggestion receives support from comparative anatomy, as amphibians, reptiles, birds, and marsupials all have

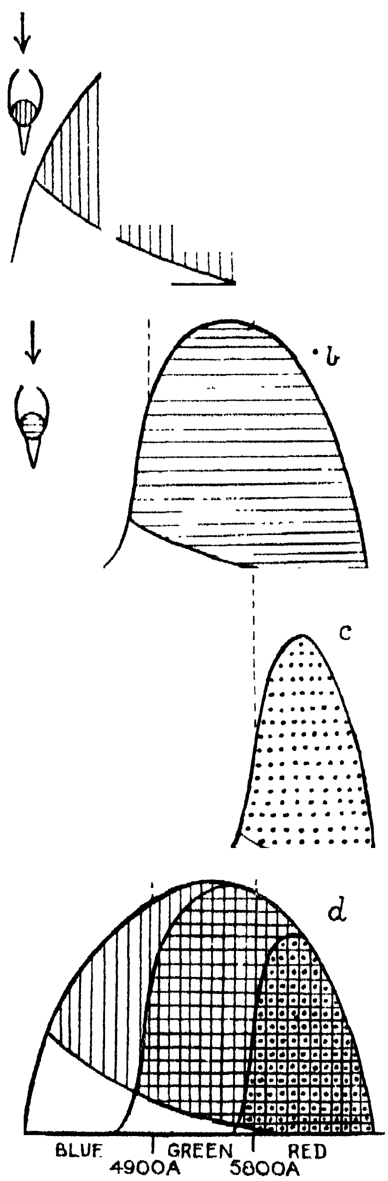

FIG. 2.—(*a*) Sensation curve for receptors sensitive to the whole of the visible spectrum.
(*b*) Sensation curve for receptors which fall off rapidly in sensitivity about 4900 A.
(*c*) Sensation curve for receptors which fall off rapidly in sensitivity about 5800 A.
(*d*) Superposition of the three sensation curves. The clear area indicates the photochromatic interval. The shift of maximum brightness with increase in intensity may be due to the effect of stimulating more than one set of receptors at the long wavelength end of the spectrum. For the hypochromat the dots would be deleted, leaving the other two sets of receptors active as in the 'green' area.
Insets: cones from hen's retina with corresponding coloured globules. The arrows show the direction of light.

coloured globules in front of the cones. As shown by the insets on the diagrams, those for the hen (red, yellow, and almost colourless) agree with the sensation curves deduced from experiments on human vision.[7] If such coloured globules should be discovered in the fovea of the human retina, the facts of colour vision would be explained. Perhaps, instead of cones with almost colourless globules, the rods may be the structures stimulated by the whole of the visible spectrum in the peripheral part of the eye. That cases of *retinitis pigmentosa* are blue blind is in favour of the blue sensation being the result of stimulation of rods.

This view is as sound from the photochemical point of view as the Young-Helmholtz hypothesis. It does not require quite so much unsupported speculation and it agrees better with the facts.

Preservation of Fish at Sea.*

FISH, even when kept in ice, soon show signs of deterioration which gives rise to 'staleness'. There are degrees of staleness, and a stale fish is not necessarily unfit for human consumption, but it is nevertheless of poor quality in the eyes of the market buyer and fetches a correspondingly lower price. If, therefore, means could be found to bring fish to market in a fresher condition after voyages of several days, the fish would sell at a better price, and the consumer enjoy a better article.

The deterioration of the fish may be caused either by intrinsic changes or by the effects of bacteria; it was one of the first aims, then, of the research to find to what degree either of these two causes was responsible for the staleness of fish. Research was carried out on board two steam trawlers specially fitted for the purpose. It has been shown that by far the more important factor in the staling of the fish is bacterial action, and that aseptic methods go far to keep the fish in good condition while at sea. This finding gives much satisfaction, as it shows at the start that results which may be of economic value to the fishermen can be obtained.

Cooling with ice does not stop bacterial action; it merely slows it down. It is therefore of importance that the fish should be thoroughly washed, after gutting, under aseptic conditions so far as possible. This, although it by no means sterilises the fish, reduces the initial contamination to a minimum and tends to keep the fish from rapid deterioration when stowed under suitable conditions. Full details and suggestions are given in the report for the equipment of trawlers with the necessary plant, and it is estimated that a capital expenditure of about £500 would be entailed and the running costs increased by about £400 a year. It remains to be seen whether the fishing trade will consider this outlay a financial proposition.

Since the introduction of the aseptic method would only extend the period during which a fish will keep fresh from 6-7 days to 10-12 days, it follows that it will only be of real value to short-distance vessels. While it would help towards keeping a larger proportion of the catches of long-distance vessels fresh, there would still be a large amount of fish caught early during the voyage that would inevitably become stale, or even bad. For the vessels making long voyages the possibilities of brine-freezing are being explored. The possible commercial advantages of this method are, however, not so sure, because, although the good flavour of the fish is preserved, the fish itself loses much in appearance; it can therefore only be taken by the salt-curers and smoke-curers.

Problems of Cotton Growing.

A RECENT publication of the Empire Cotton Growing Corporation is a detailed report of the Conference on Cotton Growing Problems which was held in August last at the Shirley Institute, Didsbury, the station of the British Cotton Industry Research Association. The conference was attended by officers of the Corporation and of the Institute, by representatives of the cotton growing countries of the Empire, Egypt, and the Research Stations of Trinidad and Amani, as well as by other workers directly engaged on problems bearing on cotton. The sixteen papers presented, with the discussions thereon, covered much ground and included in their survey problems of manufacture in the factory as well as problems of production in the field.

The main problem, around which all others orientate, is the nature of the characters which go to produce quality in cotton, the raw material of the industry. This subject was introduced, appropriately at the commencement of the conference, by Mr. Peirce. Here is raised a problem which carries back at once to field conditions, the cause of immaturity, that 'curse of Lancashire'—neps. The evidence given by Mr. Bailey from the Sudan indicates a definite relation between nepiness and drought. The discussion ranged over the effect of gins in producing neps, as well as their behaviour in the processes of spinning; and it showed how much there is still to learn with regard to the origin of neps. The subject of quality in cotton was carried a step further by two papers from the Shirley Institute: on uniformity of cotton, by Mr. Underwood, and on the methods of correlating the strength of yarn with hair properties, by Messrs. Foster and J. Gregory.

On the agricultural side many problems were reviewed. The organisation of a seed supply which will retain purity in the crop when grown, as it is in Uganda and Nigeria, by a host of small cultivators, formed the subject of a paper by Mr. Lewin, of Nigeria: the practicability of limiting the number of varieties, in view of the variations of soil and climate found in any single territory, was raised on a reference from the Uganda Government and provided an interesting discussion—not unconnected with the subject of 'new place effect', introduced by Mr. Hutchinson, of the E.C.G.C. Research Station, Trinidad; while the discussion of the efficiency of cotton picking machines, raised by the Tanganyika Government and of interest to so many cotton areas owing to the acuteness of the labour problem, indicates that at the present time there is little hope of any practical solution.

The application of more fundamental research to cotton growing problems was also discussed. Two papers, one by Dr. Maskell, formerly of the E.C.G.C. Research Station, Trinidad, and the other by Dr. Gregory, of the Imperial College of Science and Technology, and Messrs. Crowther and Lambert, of the Sudan, dealt with the application of Dr. Fisher's recent methods of plot technique and analysis of field experiments. The former dealt more particularly with the possibility of securing a co-ordinated series of experiments in the different cotton growing territories, a subject to which reference was made in an editorial article in NATURE of April 12 last; the latter recorded some interesting results obtained in the Sudan by the application of these methods. The discussion on both papers illustrated the practical limitations by which such lines of investigation are rigidly bound.

The work at Rothamsted on the investigations, under controlled conditions, bearing on that widely distributed and elusive disease 'black-arm' (*Bacterium malvacearum*) was described by Dr. Stoughton, and the discussion revealed a critical attitude by many to the value of results obtained under such abnormal conditions of growth of the host plant. Finally, Prof. Weiss introduced a discussion of the subject of grafting and chimæra formation in its application to cotton.

On Oct. 21 a meeting of the Administrative Council of the Empire Cotton Growing Corporation was held, and in presenting the quarterly report of the Executive Committee, the director referred to the fact that the Sudan Government is about to reorganise its work on agricultural research, and with the view of effecting closer co-ordination between the different research workers, a Research Policy Committee is to be set up, of which the financial secretary will be chairman. In addition, an officer will be appointed to control the whole of the agricultural research work and to be the official channel of communication between the Research Farm in the Gezira and the Sudan Plantations Syndicate. With the consent of the Corporation, this post has been offered to, and accepted by, Mr. M. A. Bailey, the Corporation's plant breeder in the Sudan.

Reference was also made at the meeting to the success which has attended the use of steel ploughs at the Corporation's Seed Farm in Nigeria, and to the gratifying fact that neighbouring farmers, who are cultivating the land adjoining the Seed Farm on a co-operative basis, intend to purchase steel ploughs from the Corporation to replace their wooden ploughs, as they appreciate the superiority of the work which they are capable of doing. It is hoped that this movement will extend, with a consequent improvement in the standard of native agriculture in the district.

In Nyasaland a programme of seed control and distribution has been carefully prepared. The variety of cotton known as *U*.4, first bred at the Corporation's Experiment Station at Barberton in the Transvaal, is giving promising results in various parts of Nyasaland under widely different climatic conditions. It is believed that it may be possible by selection to obtain both an early and a late strain of *U*.4 that will between them meet the requirements of the different parts of the Protectorate in which cotton is cultivated.

University and Educational Intelligence.

BIRMINGHAM.—Leave of absence has been granted to Profs. Brash (Dean of the Faculty of Medicine), Haswell Wilson, and Daly, to visit the United States as guests of the Rockefeller Foundation to inspect the buildings and equipment of medical schools in that country in view of the building and development of the new medical school of the University of Birmingham.

There is a considerable increase in the entry of medical students to the University this session, but the number of entries to the University as a whole shows only a slight increase.

CAMBRIDGE.—The Appointments Committee of the Faculty of Agriculture and Forestry has appointed Dr. H. G. Sanders, of St. John's College, to be University lecturer in agriculture.

The Regent House has approved the recommendations contained in the report of the Council of the Senate on Mr. Montague Burton's benefaction for the endowment of a professorship of industrial relations, with a stipend of £1200 a year. If after the payment of this stipend and the appropriate pension contribution there is still a surplus in the fund in any year, it

is provided that it shall go into a separate fund from which may be paid the expenses of the professor in visiting Geneva, in order to keep in touch with the International Labour Office, or in investigating at first hand industrial relations in America. The new chair is to be called the Montague Burton Professorship of Industrial Relations and will be primarily assigned to the Faculty of Economics and Politics.

OXFORD.—At a meeting of Congregation held on Nov. 11, a decree was passed establishing regulations for the Joint Coal Mining Diploma of the Universities of Oxford and Birmingham. The decree provides that candidates for the diploma who are graduates of the University of Oxford must have obtained a class in the final honour school of engineering science, and must have attained a satisfactory standard in geology as a special subject. They must also present certificates of at least four months' practical experience in mining, and must attend the diploma course in mining at the University of Birmingham, extending over one session.

On Nov. 13, Prof. Pannekoek, of the University of Amsterdam, delivered, on behalf of Prof. Milne, a lecture on "Researches in the Intensities of Absorption Lines in Solar and Stellar Spectra". By means of certain formulæ and substitutions, which he employed with great fluency and readiness, he showed how the investigation of these intensities is capable of throwing light on the chemical constitution of solar and stellar atmospheres. Certain discrepancies between the calculated and observed results require further research. They may possibly indicate (as suggested by Prof. Milne) that some physical data need reconsideration in the light of astrophysics.

NOTICE is given by the Institution of Chemical Engineers, that application forms, particulars of the 1931 associate membership examination of the Institution, and a memorandum on "The Training of a Chemical Engineer" are obtainable from the Hon. Registrar, Institution of Chemical Engineers, Abbey House, Westminster, S.W.1. The latest date for the return of application forms is Dec. 22.

Historic Natural Events.

Nov. 24, 1639. Transit of Venus.—The rare occurrence of a transit of the planet Venus across the sun's disc was first predicted and then observed on this date (old reckoning) by Jeremiah Horrocks and also by his friend Wm. Crabtree to whom he had communicated his prediction. "I then beheld a most agreeable spectacle, the object of my sanguine wishes, a spot of unusual magnitude and of a perfectly circular shape, which had already fully entered upon the sun's disc on the left, so that the limbs of the Sun and Venus precisely coincided, forming an angle of contact. Not doubting that this was really the shadow of the planet, I immediately applied myself sedulously to observe it." Only four other such transits have been seen, those of 1761, 1769, 1874, and 1882. The next is due in 2004.

Nov. 23-24, 1926. Rock Fall at Roquebillière.—Following heavy rains, a crevasse opened on the steep flank of the Maritime Alps above Roquebillière on Nov. 22. Suddenly on the night of Nov. 23-24 a great mass of rock broke away and fell on the village, destroying a dozen houses and killing 25 persons. The catastrophe was due to the saturation of the ground above a sloping bed of clay, down which the whole mass slipped.

Nov. 26-27, 1703. Defoe's Great Storm.—On the night of Nov. 26-27 the southern half of England was visited by a storm unequalled for at least 300 years and possibly for far longer. Daniel Defoe, the author of "Robinson Crusoe", compiled a detailed and graphic account of the disaster, with the help of correspondents in all parts of the country. The greatest intensity of the storm was experienced to the south of a line from Pembroke to Yarmouth, and here the damage was so great that masses of lead from the roofs were rolled up and carried considerable distances. Houses were blown down, unroofed, or otherwise damaged, and the cost of building materials rose to three or four times the normal level. Eddystone lighthouse was destroyed, with Winstanley, its designer; and according to Defoe's account there was great loss of shipping. The loss was greatest on the south and south-east coasts of England and even in the Port of London many ships were driven aground. On the shores of the Severn the damage was accentuated by an abnormally high tide. At Bristol the water rose eight feet above the previous highest level. In south-west England the winds began from south-west and veered to north-west; in south-east England they began from south-south west and veered to west. There were several interesting peculiarities: the storm was generally accompanied by lightning, though the wind drowned the noise of the thunder. A 'spout' or tornado was observed at 4 P.M. on Nov. 26 near Oxford, and possibly elsewhere; and among the buildings of London the wind produced remarkable eddies, the damage to the roofs taking place on the eastern or leeward sides of the houses. In Kent the trees and grass were covered by a deposit of salt 25 miles from the sea. On Nov. 28 there was a very high tide in the Thames, which added to the confusion by flooding riverside London. The st[orm] ravaged Holland on Nov. 27, struck Hanov[er] and Copenhagen on the night of Nov. 27-28, while severe gales which may have been due to the same storm were afterwards reported from the Baltic, Sweden, Finland, and northern Russia. These led Defoe to conjecture that the storm, originating in North America, may have travelled entirely round the globe, losing force in the Arctic and dying out near its birthplace.

Nov. 26-27, 1898. "Portland Storm". A violent storm traversed the coast of New England, accompanied by a heavy fall of snow. One hundred and forty-two ships were wrecked, with a loss of 455 lives, including the steamship *Portland*, which left Boston in spite of a storm-warning from the Weather Bureau, and foundered off Cape Cod, this disaster costing 175 lives.

Nov. 26-29, 1921. Glazed Frost.—During a period of strong northerly and north-easterly winds, snow and freezing rain fell steadily for more than three days in Massachusetts, forming thick coatings of ice on all trees and telegraph wires. Wires one quarter of an inch in diameter carried ice two inches in thickness, and weighed $1\frac{1}{4}$ lb. per foot, and whole rows of telegraph and trolley-car poles were snapped off at the base, while almost every tree lost at least one good-sized branch. Communications and electric supply were interrupted for days, several people were injured and a number of horses killed.

Nov. 27, 1909. Hurricane. A violent hurricane struck the Cocos Islands (Keeling Group) soon after 7.30 P.M.; the wind and high seas did considerable damage. At 8.15 P.M. cable communication was interrupted owing to the vibration of the instruments. The centre of the storm passed over about 10 P.M., the barometer reading being 947 mb. (27·96 in.).

Societies and Academies.

LONDON.

Society of Public Analysts, Nov. 5.—**G. M. Moir**: The determination of the milk proteins. By mixing definite quantities of milk with a suitable acetic acid and sodium acetate buffer, maximum casein values are obtained between *p*H 4·5 and 4·7. Casein thus precipitated is identical with the substance precipitated by acetic acid alone at *p*H 4·2. For the combined determination of albumin and globulin the filtrate obtained from the iso-electric precipitation of the casein is treated with trichloroacetic acid to give a concentration of about 4 per cent, and the nitrogen the resulting precipitate determined by Kjeldahl's ethod. Casein and globulin are determined by pre-pitation with neutral saturated magnesium sulphate r sodium sulphate, and the individual proteins calcu-ated by difference. **S. G. Clarke**: The lead reduction ethod for the volumetric determination of tin, and he interference of copper and antimony. Tin is etermined by Powell's method of reduction from e stannic condition by means of lead, and direct tration with iodine, in an atmosphere of carbon oxide. Copper causes the results for tin to be too w in direct proportion to the amount of copper esent. Antimony also interferes, a considerable nount of tin being removed from the solution by precipitation of the antimony; this reacts with iodine during the titration. **W. J. Agnew**: A w method for determining traces of chromium in el. Chromium is oxidised with potassium per-anganate, excess permanganate being reduced by hydrochloric acid. The iron is then precipitated with sodium carbonate, and the dichromate determined by Evans's colorimetric method based on the purple coloration which it gives with diphenylcarbazide.

Linnean Society, Nov. 6. **J. G. de Man**: On a new species of the genus *Hoplophorus* (*Oplophorus*) H. M. Edw. A new species of deep-sea prawn belonging to the genus *Hoplophorus*. The specimens were taken from the stomach of a groper, *Polyprion prognathus*, captured in 2 fm. of water off the east coast of the South Island of New Zealand, at a place where deep water comes to within a short distance of the shore. **Isabella Gordon**: Brachyura from the coasts of China. In the endeavour to find satisfactory systematic characters for the discrimination of species and genera, particularly in the families Xanthidæ and Portunidæ, attention was given to the form of the abdominal appendages in the male sex. These appendages appear to afford a ready and reliable means of distinguishing males of the species discussed here and also in other species. **H. H. Allan**: Some remarks on wild hybrids in the New Zealand flora. Wild hybrids are very prevalent in the New Zealand flora, and those hybrids occur, for the most part, as highly polymorphic swarms, often between extremely diverse species, and showing a high degree of fertility. Where a species occurs alone it shows no 'variability', apart from environmentally induced modifications, and reproduces itself truly. The many so-called 'variable' species of the flora are really artificial groups compounded of true-breeding forms along with various hybrids. These artificial groups are now being studied by means of artificial hybridisation.

PARIS.

Academy of Sciences, Oct. 20. The president announced the death of Adolf Engler, *correspondant* for the Section of Botany.—**Ernest Esclangon**: New observations of the trans-Neptunian planet and a new determination of its orbit.—**Georges Perrier**: The fourth general assembly of the International Geodesic and Geophysical Union; Stockholm, August 1930.—**Serge Bernstein**: An interpolation formula.—**P. Vincensini**: Surfaces of constant total curvature.—**Paul Delens**: Representations of complex elements and conformal transformations on the sphere.—**S. Diary of Societies.

FRIDAY, NOVEMBER 21.

ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botany Department, Imperial College of Science), at 2.30.—Dr. H. I. Barin: The Specific Resistance of Willows to Insect Attack.

DIESEL ENGINE USERS' ASSOCIATION (at Caxton Hall), at 3.30.—Major W. H. Goddard: The Application of Diesel Engines to Road Transport.

ROYAL SOCIETY OF MEDICINE (Balneology and Climatology Section), at 5.—Dr. E. G. Thomson: The Role of Hydrology in Preventive Medicine.

PHYSICAL SOCIETY (at Imperial College of Science and Technology), at 5.—Dr. E. T. Paris: The Determination of the Acoustic Characteristics of Sharply-resonant Hot-wire Microphones.—Dr. K. R. Rao: The Spectrum of Doubly Ionised Arsenic.—Dr. H. C. Bowker: The Effect of Temperature on Spark Potential.—Dr. F. L. Bates: The Curie Points.—Demonstration of an Instrument for Compounding Curves designed by Dr. Haugh.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Demonstration of Specimens illustrating the Enlargement of the Prostate, with an Account of the Present State of Knowledge concerning the Etiology of the Condition.

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (in Muspratt Lecture Theatre, Liverpool University), at 6.—Dr. J. H. Reid : Nicotine.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—A. Eagle and R. M. Ferguson : The Coefficients of Heat Transfer from Tube to Water.

SOCIETY OF DYERS AND COLOURISTS (at Literary and Philosophical Society, Manchester), at 7.—Dr. J. L. Hankey : The Treatment of Aniline Black subsequent to Ageing.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group) (Informal Meeting), at 7.—W. H. Clark : A Talk on Lantern Slides.

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7.30.—R. P. H. Graham : Ancient Clocks and Horological Curiosities.

INSTITUTION OF STRUCTURAL ENGINEERS (at Merchant Venturers' Technical College, Bristol), at 7.30.—G. F. C. Caswell : The Erection of Steelwork.

INSTITUTE OF CHEMISTRY, at 8.—B. F. Howard : Some Notes on the Cinchona Industry (Streatfeild Memorial Lecture).

ROYAL SOCIETY OF MEDICINE (Obstetrics and Gynæcology Section), at 8.—Dr. T. W. Eden, Dr. J. S. Fairbairn, and others : Discussion on the Interim Report of the Departmental Committee on Maternal Mortality and Morbidity.

INSTITUTE OF BREWING (at Institution of Electrical Engineers), at 8.15.—Dr. E. S. Beaven : The Culture of Barley for Brewing (Horace Brown Memorial Lecture).

ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section), at 8.30.—Clinical Meeting.

INSTITUTE OF CHEMISTRY (Leeds Area Section) (at Leeds).—Annual General Meeting.

SOCIETY OF DYERS AND COLOURISTS (London Section).—Prof. F. M. Rowe : Properties of Insoluble Azo Colours on the Fibre.

SATURDAY, NOVEMBER 22.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—H. Plunket Greene : What Schubert did for Song.

BRITISH PSYCHOLOGICAL SOCIETY (at Royal Anthropological Institute), at 3.30.—Extraordinary General Meeting.

MONDAY, NOVEMBER 24.

INSTITUTE OF ACTUARIES, at 5.—Sir Alfred Watson : The Analy Sickness Experience.

INSTITUTION OF MECHANICAL ENGINEERS (Graduates' Section, London), at 6.45.—C. H. Russell : Machine Tools.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—J. Paley Yorke and others : Discussion on The Syllabuses of Day and Evening Courses in Electrical Engineering—Do they meet Commercial Requirements?

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Birmingham University), at 7.—G. Bianchi : Some Data concerning Railway Electrification in Italy.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—J. H. Reynolds : Slides and Films in the Exhibition of the Society.

INSTITUTION OF AUTOMOBILE ENGINEERS (Glasgow Centre) (at 39 Elmbank Crescent, Glasgow), at 7.30.—J. Bradley and S. A. Wood : Some Experiments on the Factors affecting the Motion of a Four-wheeled Vehicle when some of its Wheels are locked.—J. Bradley and R. F. Allen : Factors affecting the Behaviour of Rubber Tyred Wheels on Road Surfaces.

ROYAL SOCIETY OF ARTS, at 8.—Prof. C. R. Darling : Modern Domestic Scientific Appliances (Cantor Lectures) (1).

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8.—J. L. Payne : A Case of Re-plantation and the Result after Nine Years.—Dr. A. F. Hurst : The Teeth and the Stomach.

MEDICAL SOCIETY OF LONDON.—Clinical Evening.

TUESDAY, NOVEMBER 25.

ROYAL SOCIETY OF ARTS (Dominions and Colonies Section), at 4.30.—G. E. Woods Humphrey : The Development of Air Communication in Africa.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Sir W. H. Bragg : Two Old Friends of the Royal Institution (2) : Warren de la Rue.

EUGENICS SOCIETY (at Linnean Society), at 5.30.—W. T. J. Gun : The Heredity and Environment of our Empire Builders.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Western Centre) (at Engineers' Club, Manchester), at 7.—G. Bianchi : Some Data concerning Railway Electrification in Italy.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—O. Bloch : How it Works in Photography (3) : The Emulsion Maker's Point of View.

SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield), at 7.30.—G. C. Waite : Preparation of Standard Steels.

DESIGN AND INDUSTRIES ASSOCIATION (at Institution of Electrical Engineers), at 8.—R. D. Best and R. McGrath : Discussion on Modern Electric Lighting and Lighting Fixtures.

WEDNESDAY, NOVEMBER 26.

BRITISH ASTRONOMICAL ASSOCIATION (at Sion College), at 5.

NEWCOMEN SOCIETY FOR THE STUDY OF THE HISTORY OF ENGINEERING AND TECHNOLOGY (Annual General Meeting) (at Caxton Hall), at 5.30.—Rhys Jenkins : Early Fire Extinguishing Engines.

INSTITUTION OF ENGINEERS IN CHARGE (jointly with Association of Supervising Electrical Engineers) (at Magnet House, Kingsway), at 7.15.—H. J. Eley : Ventilation by Air Movement.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Tees-side Branch—Graduate Section) (at Cleveland Scientific and Technical Institution, Middlesbrough), at 7.30.—O. E. Fletcher : Further Aspects of Boiler Design.

ROYAL SOCIETY OF ARTS, at 8.—Prof. W. A. Bone : The Chemical Constitution of Coal.

THURSDAY, NOVEMBER 27.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Dr. L. C. Martin : Colour Vision (2).

INSTITUTE OF METALS (Birmingham Local Section) (at Chamber of Commerce, Birmingham), at 7.—Dr. O. F. Hudson : Solders.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Kinematograph Group), at 7.—Projection of Films.

INSTITUTE OF CHEMISTRY (Leeds Area Section) (at Great Northern Hotel, Leeds), at 7.15.—Annual General Meeting.

INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre—Dublin) (at Trinity College, Dublin), at 7.45.—L. J. Kettle and W. Tatlow : Progress in the Electrical Industry.

MEDICO-LEGAL SOCIETY (at 11 Chandos Street, W.1), at 8.30.—Dr. F. C. Martley : The Importance of Blood-grouping Tests in Paternity Cases.

FRIDAY, NOVEMBER 28.

GENETICAL SOCIETY (at Linnean Society), at 3.—A. E. Gairdner and Dr. C. D. Darlington : The Theory of Ring-formation exemplified by *Campanula persicifolia*.—J. Philp : An Explanation of the Inheritance of Double Flowers in *Matthiola incana R.Br.* based on Cytological Evidence.—At 3.45.—Prof. A. H. R. Buller : Sexual Phenomena in the Higher Fungi.—C. Diver : Studies in the Genetics of the Common Garden Snail, *Helix aspersa*.—A. A. Moffett : Cytology of Pomoideæ.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle-upon-Tyne), at 6.—W. S. Hinde : The Ocean-going Tramp Steamer from the Owner's Point of View.

INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section), at 6.15.—Lt.-Col. H. E. O'Brien : Electric Traction (Students' Lecture).

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—E. Batten and others : Discussion on Export Trade Emancipation.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—G. H. Willett : Photography applied to Science.

INSTITUTION OF CHEMICAL ENGINEERS.—S. Mayne : The Sources of Published Technical Data and how they should be used.

SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section) (jointly with Society of Dyers and Colourists) (at Glasgow).—F. W. Lake : Dyeing and Dry Cleaning.

SATURDAY, NOVEMBER 29.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—H. Plunket Greene : Ver. in Song.

PUBLIC LECTURES.

FRIDAY, NOVEMBER 21.

INSTITUTION OF PROFESSIONAL CIVIL SERVANTS (at Surveyors' Institution), at 5.30.—Col. C. H. Bressey : Some of our Road Problems.

TOWN HALL, GATESHEAD, at 7.30.—Dr. M. Ray : The Treatment of Rheumatism (Chadwick Lecture).

SATURDAY, NOVEMBER 22.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—H. Nairs : A Survey of Costume from Prehistoric Times to the Elizabethan Era.

UNIVERSITY OF CAMBRIDGE (at Newnham College), at 5.—Prof. A. V. Hill : Biology in Education (Henry Sidgwick Memorial Lecture).

MONDAY, NOVEMBER 24.

UNIVERSITY OF LEEDS, at 5.15.—Prof. R. Robinson : The Colouring Matters of Red and Blue Flowers, Fruits and Blossoms.

TUESDAY, NOVEMBER 25.

KING'S COLLEGE, LONDON, at 11 A.M.—S. P. Turin : Russian Farming and Agriculture.—At 5.30.—Miss Hilda D. Oakeley : The Approach to Reality Through History and Practice.

WEDNESDAY, NOVEMBER 26.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—L. Ward : The Prevention of Accidents in Factories and Workshops.

KING'S COLLEGE, LONDON, at 5.30.—H. T. Tizard : Scientific Industry.

UNIVERSITY COLLEGE, LONDON, at 5.30.—A. M. Wijk : Stockholm and Environs. (Succeeding Lectures on Dec. 3 and 10.)

BELFAST MUSEUM AND ART GALLERY, at 8.—J. Taylor : Venetian Art.

UNIVERSITY OF READING, at 8.15.—J. H. Coste : The Object and Method of Sewage Treatment (Chadwick Lecture).

THURSDAY, NOVEMBER 27.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Dr. H. Chapple : Contraceptive Responsibilities of the Medical Practitioner.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 5.—Dr. J. S. Owens : Atmospheric Pollution.

FRIDAY, NOVEMBER 28.

ROYAL SOCIETY OF ARTS, at 5.30.—Sir Robert Philip : The Outlook on Tuberculosis : Changing Orientation (Malcolm Morris Memorial Lecture).

SATURDAY, NOVEMBER 29.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss I. D. Thornley : Some Mediæval Beasts, Real and Otherwise.

CONGRESS.

FRIDAY, NOVEMBER 21.

PUBLIC HEALTH CONGRESS (at Royal Agricultural Hall).

At 10.30 A.M.—Discussion on Sterilisation of the Unfit.

At 11 A.M.—Meeting of Institute of Public Cleansing.

H. Cook : The Future of Public Cleansing Work.

At 3.—Prof. C. S. Myers : Industrial Psychology and Public Health.

Meeting of Association of Superintendents of Parks and Botanic Gardens.

W. W. Pettigrew : Public Parks in Relation to Public Health.

Meeting of British Red Cross Society Hospital Library.

State Research in Chemistry.

IF Prof. G. T. Morgan's presidential address to the Chemistry Section of the British Association, at the recent meeting at Bristol, was not of the kind that provides arresting headlines for the daily Press, the reason is to be sought rather in deliberate choice of treatment than in lack of material, for we live in times—to many of us it still seems strangely novel—when State experiments and chemical research are both regarded as good copy, and fair game for the alliterative caption. The British Association exists primarily for the advancement of science as an element of culture; the addresses are designed to provide a bridge between the minds of two groups of thoughtful people, of whom one group is formed of pioneers engaged in the search for a particular kind of knowledge, whilst the other includes those similarly engaged elsewhere, as well as members of the general public who are interested to know something of the habits of this thing called scientific research which seems to touch their lives at every turn.

Instead of providing a critical survey of selected problems or an account of experimental advance along some well-defined path, Prof. Morgan offered a contribution to the study—in which, from various points of view, every member of his audience could participate—of a certain phenomenon, namely, the application, under the direct control of the State, of centralised and co-ordinated team-work to promote the more rapid advance of a science. Just as in the early stages of an investigation into natural effects it is most appropriate to record observations with accuracy and to determine what relations exist between the new and the old, so in this instance it was appropriate that the director of the Chemical Research Laboratory should avoid prophecy and special advocacy, but should confine his address chiefly to statements of fact and observations. His address forms a valuable basis to which, as time passes, there will be added the results of experience and of thoughtful suggestion and criticism; we of strong faith in the great future which lies in the path of this still new adventure welcome the convincing proof of vitality with its promise of robust growth.

The national value of such research as is being carried on at Teddington is, of course, no longer in question; no longer—in the abstract, at any rate—is it even ignored. Should it be asked how distinctively *national* in its significance is the technical work performed there, the reply might quote an example of the highest importance offered by the

studies on low temperature tar. The abatement of the smoke nuisance has long been a matter of popular discussion, but complaints have for the most part 'ended in smoke', so indissolubly wedded is the Briton to the coal fire which turns his house into a home. The new process of low temperature carbonisation of coal has at length given him a fuel which, while preserving his domestic amenities, contributes in no small measure to a solution of the problem of diminishing atmospheric pollution. If the price of this smokeless fuel could be made more attractive, there is no doubt that its use would quickly become widespread, and in time perhaps universal, to the great content of the guardians of the public health and to the convenience of aeronauts and astronomers. The price of the fuel depends not only on the output but also on the opportunities which exist for the exploitation of the by-products- aqueous liquor and tar. Now this tar differs markedly in its composition and characteristics from that hitherto produced, and its exhaustive examination, necessarily the first step in its exploitation, is pioneering work of first importance. It is self-evident that such an investigation is not only one which will be lengthy and will demand co-operative effort in a high degree, but also one which when developed along industrial lines can scarcely fail to lead to definite economic advantage, no less than to noteworthy contributions to chemical and possibly geological science.

It would be difficult at the present stage to estimate the full extent of the advantage to be anticipated from the development of low temperature carbonisation; it is sufficient to indicate that a general stimulation of industry following the return of coal to its former economic status is not to be excluded from view. Apart, however, from such mundane, if vital, considerations, is the impetus which the work will give to the world-wide advance of organic chemistry by providing (as did that on its elder brother, 'coal tar') starting-points for synthesis and relationships for elucidation. Already the presence of a substantial proportion of pyrocatechol has been demonstrated, a coloured hydrocarbon has been separated, and it has been observed that, speaking generally, the products tend to be the methyl derivatives of their high temperature tar analogues.

Surely no better example of the unreality of division of chemistry into 'pure' and 'applied' sciences is needed. Application can never precede discovery but often promotes it; and leaders of the chemical profession, whether their outlook be from a chair or from a board room, see the same fundamental knowledge supporting their endeavours and the same fundamental difficulties obstructing them. Work of this calibre can be represented in the museum of the laboratory only by a few shelves of bottles and specimens; their neighbours are no less significant in their relation to the development of a science, for they are early examples of pure substances which have been prepared by simplified processes rendered possible by the application of moderate pressure, whilst the series of primary alcohols (including ethyl), aldehydes, and acids derived from the catalytic interaction of carbon monoxide and hydrogen, offers both an intriguing contribution to the study of catalysis and a material success capable of industrial expansion. Each glass case that is opened discloses the steady progress of pioneering exploration where practice has outrun perception, as with synthetic resins; where the engineer has solved problems of a new technique (our thoughts return to the first air-pump and its contribution to chemical advance); in the new iatro-chemistry, where therapy and the 'architecture of molecules' move forward with mutual aid, not disdaining to strew their path with substances of curious behaviour and with incidental contributions to the study of valency. So essentially practical a matter as the corrosion of metals is not without its surprises and its puzzles; who would have thought that the green patina on copper roofs is not verdigris but basic copper sulphate eventually corresponding in composition with the mineral brochantite? And why does iron not rust so quickly when confined in a muslin cage as when not so confined?

This is the type of work which engages the attention of a staff of twenty-five chemists and thirty-two others, housed in a building adjacent to the National Physical Laboratory, and it is fully worthy of the attention of a State organisation. Like the German Reichsanstalt, the Chemical Research Laboratory owes its parentage to conditions evolved from war, although the former institution has now arrived at years of maturity. Neither can the Laboratory claim seniority in Great Britain as a public institution devoted to the prosecution of scientific research and its application to industrial needs, for its immediate neighbour has during the past thirty years discharged that duty. An essential difference in the nature of the work undertaken by the two institutions is to be found in the fact that whilst that of the Chemical Research Laboratory consists exclusively of original research, that of the National Physical Laboratory

includes testing, and hence provides substantial opportunities for fee-earning. That this should be so does not, of course, detract *ipso facto* in any way from the quality of the research carried on concurrently with the routine testing, which constitutes an essential public service. Nevertheless, it was doubtless wise not to burden a chemical laboratory, created specifically for exploration, with duties of a like nature. Should the usual facilities for obtaining such service prove inadequate or non-existent, there would presumably be little technical difficulty associated with a modification of the present policy.

We have already remarked that the Chemical Research Laboratory is the home of centralised and co-ordinated team-work. The unit is not the individual worker, whose efforts are likely to be discounted—not always by his own fault—through lack of adequate co-operation with others, but the 'working party'. As a coherent team the working party receives from the director its mandate to operate in a certain field: as a team it collects information and gathers experience. Not least among the national services rendered by the Laboratory must be counted the training, both in method and in spirit, of leaders in chemical research, particularly of those who will carry the habit of co-operation with them into the industrial world. It must not be forgotten that such 'key' problems as have been entrusted to the Laboratory require for their solution not only skill, knowledge, and strategy of a high order, but also substantial resources, expanding facilities, and the application of sustained forces.

Prof. Morgan refers to the undertaking as "a State experiment"; it is from one point of view an experiment, but not one of the result of which there need be much doubt. When Francis Bacon gave his opinion that States should not try experiments, he added the qualification "except the necessity be urgent or the utility evident", advising that it would be "well to beware that it be the reformation that draweth on the change, and not the desire of change that pretendeth the reformation". Reformation in our national attitude towards research (particularly chemical research, in which the material returns are often subject to but little delay) and towards chemical industry there has indeed been, and changes in our institutions have occurred in consequence—all too slowly and timidly, as some think who should be in a position to judge. These harbour no doubts concerning the utility or the urgency of the necessity. There may, of course, still be those who regard the 'experiment' as a novelty to be suspect: merely an innovation in tune with modern custom, a fashionable enterprise of which some indefinite good may come. Others, and we may hope the majority, see in it an effective new tool at the service of an industrial nation; some indeed, perhaps those who most clearly read the signs of the times, think of such a development as this in terms of future employment, of the standard of living, and of human happiness and well-being. *Scientia imperii decus et tutamen.*

Kepler's Letters.

Johannes Kepler in seinen Briefen. Herausgegeben von Max Caspar und Walther von Dyck. 2 Bande. Band 1. Pp. xxviii + 396. Band 2. Pp. xvi + 348. (München und Berlin: R. Oldenbourg, 1930.) 20 gold marks.

THE present year is the three-hundredth anniversary of the death of Kepler. The volumes before us mark the occasion. All that remains of Kepler, and it is a great deal, is already available in Frisch's edition. But Frisch is frankly unreadable. He had all the faults that sometimes accompany German thoroughness. In particular, as the editors of the volumes now before us remark, the letters come off very badly, being cut up and distributed here and there according to the subject treated of.

Max Caspar and Walther von Dyck have prepared a book for German readers which has the intention of bringing the man rather than the scientific ideas of three centuries ago before us; in fact, many of the scientific passages are omitted or compressed. Kepler's life was passed in evil times. A great deal of it was passed in penury and family distress. The counter-Reformation, with the vindictiveness of those who had come back to what they regarded as their own, framed the early part. When he went to the service of the Emperor Rudolph in Austria, an endless war with the Turk surged on the confines of the country and crippled civilised efforts. The Thirty Years' War wrapped the end in spectral gloom—though by that time Kepler himself was very tough. Messrs. von Dyck think that the present times are evil times, too, and that these letters will fortify Germans and do them good. The letters are a selection of those by Kepler and to him. They exist mostly in Latin, and these have been translated and make pretty easy reading, very different from those in the German of his time, where prolixity, long involved sentences, bad spelling, and the exasperating

practice of mixing Latin phrases with his vernacular make heavy going.

The book is a scholarly book and well done, though not intended as a prime authority. It is meant for current reading and has only a brief index. It includes a bibliography of sources where originals may be found, though each letter is not ascribed to its source. It includes also a brief list of dates and facts for all the persons referred to, and a certain number of portraits and other illustrations, well reproduced from interesting originals.

Taking the book, then, as we are meant to take it, what impression do we form of Kepler? Certainly the editors have banished a good deal of fog, but what we see is still not clear. Kepler was not one of those men of genius who can turn each matter that they touch into gold for all time by a single phrase. One reads his letters about religion, and of the refusal of the sacrament to him, and again of how he declines the proposal of his friend the Jesuit Guldin that he should join the Church of Rome, only to be led deeper and deeper into details that are long since dead and better forgotten. The same is true of the letters dealing with the case when some spiteful neighbour prosecuted his mother for witchcraft, and although the charge seems to have been entirely baseless, actually succeeded in spinning it out from year to year and incarcerating the old lady and threatening her with torture, in spite of Kepler's many letters to the Grand Duke of Württemberg urging that it should be brought to an issue. Perhaps of necessity they are detail, detail, detail.

Be that as it may, it is to be feared that Kepler, before he discovered Kepler's Laws and became famous, must have seemed, to those of his contemporaries who had enough contrivance to dodge the lesser troubles of this world, a formidable bore, always in poverty and domestic embarrassment, an able man without a spark of humour, writing immense letters about himself or any other subject, ticking off each with level emphasis and immense prolixity of detail. He had an unhappy life. Perhaps he expected people to have unhappy lives. He mentions the burning of Giordano Bruno, and that he was said to have shown a firm face in his trials, but expresses no horror of the deed. One of the portraits of him shows a face of fearful intensity, and energy, and frustration. It was not his fault that the world ill-treated him. The Emperor Rudolph II. wrote a rescript to his treasury to pay his pension, and the treasury did not pay it. His wife's relatives disapproved of his marriage and did not pay. Still, what have we to do with all that? He is dead long since, and we have our own bothers, of which he knew nothing.

There are, however, other personal features in Kepler's story that one would read these letters very ill if one did not see. There was no subtlety in Kepler. Fate bludgeoned him, but he did not bow his head. *Hier steh' ich, ich kann nicht anders*, might have been said by him, if he had had any instinct for a vital phrase. He sent Galileo his book "Mysterium Cosmographicum", and Galileo replied politely with guarded words this was thirteen years before he used a telescope—that perhaps he believed the Copernican theory more than circumstances allowed him to say. Kepler answered with the insistence of a man who sees one truth and sees it only. He had the kind of courage that a bull has he made straight for his object. Besides that, he had a warm and generous heart. He cherished his old and true friends, and he had some, though they were not able to help him much. The great event of his life was his meeting with Tycho Brahe. Tycho, when established under the protection of Rudolph, after his exile from Denmark, asked Kepler to be his guest. Kepler went, and stayed with him for six months; and Tycho, like the great gentleman he was, placed his castle and family and servants, as well as his scientific stores, at Kepler's service. In the end something went wrong, and Kepler lost his temper and behaved outrageously; and there is a letter, full of noble remorse, to Tycho, taking all the blame Tycho again behaved like a great gentleman and bore no grudge; and from that association we have the planetary laws, and how much more that is later history.

Kepler's scientific ideas do not really enter into these volumes, but they cannot be kept out. If the essence of mathematics is form, he had no mathematical genius. Number was what interested him. He had an intense conviction that the secret relations of things would be found in the relations of number. It led him elaborately astray twice—in relating the musical intervals with the distances of the planets, and in relating the latter with the dimensions of the five regular solids. Only later was his persistence in calculating rewarded in finding the planetary laws.

Great pains and labour must have gone in producing this book, and the editors have made the circle that is interested in such things their debtors by rendering the material so available. It is to be hoped that that circle will not be a small one.

R. A. S.

The South Atlantic Islands.

British Museum (Natural History). Report on the Geological Collections made during the Voyage of the Quest *on the Shackleton-Rowett Expedition to the South Atlantic and Weddell Sea in 1921-1922.* Pp. ix + 161 + 3 plates. (London: British Museum (Natural History), 1930.) 12*s.* 6*d.*

THE voyage of the *Quest* in 1921-22, in spite of the change of plans after the tragic death of Sir Ernest Shackleton, has thrown important light on the geology of the South Atlantic islands owing to the energy of the geologist, Mr. G. Vibert Douglas, and the use that has been made of his collections by Mr. Campbell Smith. The specimens were presented by Mr. Rowett to the Mineral Department of the British Museum (Natural History), and an authoritative account of them, with several new analyses, has been prepared by Mr. Campbell Smith and other experts.

The volume includes twelve reports, including descriptions by Mr. Vibert Douglas of South Georgia and Tristan da Cunha and an account, in conjunction with Mr. Campbell Smith, of the rocks of Zavodovskii Island and of rock fragments, sedimentary, metamorphic, and plutonic, dredged from the Weddell Sea. Mr. Campbell Smith, the editor of the volume, describes the petrography of Tristan da Cunha, Gough Island, St. Helena, and Ascension; Dr. G. W. Tyrrell, the geology and petrography of South Georgia; Mr. G. H. Part, the rocks of St. Vincent; Dr. H. S. Washington, those of the St. Paul's Rocks; Dr. C. E. Tilley, the basalts of Elephant Island, South Shetlands; Miss A. Vibert Douglas, the deep-sea deposits, and Prof. Gordon, fossil wood from South Georgia.

The contributions which throw most light on the history of the South Atlantic are those on South Georgia, regarding which there are two theories. Suess interpreted the island as a fragment of an arc that once connected the main Andean chain with its extension in Grahamland. This view is supported by the claims that South Georgia consists of a series of overfolded and faulted Mesozoic rocks and that its igneous rocks are represented in the Andes of the Argentine. According to the alternative view, which is based mainly on the observations and collections of Mr. D. Ferguson, South Georgia is a remnant of an old South Atlantic land and the connexion of the Andes and Grahamland passed to the west of it. This view rests on the conclusions that South Georgia consists of three series of rocks, of which one is Lower Palaeozoic, the second Mesozoic, and the third includes igneous rocks of the Atlantic type, which are also found in the pre-Andean foundation of Argentina, while the typical Andean igneous rocks are unknown in South Georgia.

The new evidence is consistent with the latter theory. The only new fossil found is a piece of fossil wood; it is referred to that indefinite genus *Dadoxylon* (*Araucarioxylon*), by Prof. Gordon, who regards its age as more likely to be Mesozoic than Palaeozoic. This identification is consistent with the age assigned to the Upper and Middle parts of the Cumberland Bay Series. The claim that the whole of the sedimentary rocks belong to one Mesozoic series is not supported either by Mr. Douglas, who argues in favour of the separation of the two sedimentary series by an unconformity, or by Dr. Tyrrell, who points out the difference in composition between the older and newer sediments. The main change that seems not unlikely in Ferguson's classification is that the beds which yielded his older fossils may be more closely associated with the underlying Cape George Harbour series than with the Cumberland Bay series as now restricted by Dr. Tyrrell.

The structure and relations of South Georgia can only be settled by the collection of more fossils, which will establish horizons which are at present provisional. Fortunately, further fossils have been discovered by Dr. Holtedahl and are being investigated by Prof. Wilckens. It is to be hoped that these fossils will solve the South Georgia problem.

The contribution to the petrography of the St. Paul's Rocks, by Dr. H. S. Washington, has also an important bearing upon the history of the South Atlantic. He shows that the rock is a wehrlite-dunite, which has undergone change by pressure, and includes such characteristic metamorphic mineral species as jadeite and actinolite. Dr. Washington nevertheless hesitated before accepting the rock as non-volcanic because of its geographic position, and he considers the possibility of its being a submarine lava. He concludes, however (p. 134), that "the rock is almost undoubtedly metamorphosed or shows signs of pressure", also (p. 136) that jadeite "is generally regarded as being characteristically, if not exclusively, of metamorphic origin". He concludes, "if it were not known whence the specimens came, the microtexture, with the mineral and chemical composition, would lead unhesitatingly to the belief that the rock is a somewhat metamorphosed peridotite, and probably of plutonic origin"; and he considers that the St. Paul's Rocks are part of the Atlantic floor that has been upraised to the surface, and that the wehrlite block found by Daly at Ascension indicates that that island also stands on a continental basis. Dietetics.

(1) *A Laboratory Handbook for Dietetics.* By Prof. Mary Swartz Rose. Third edition. Pp. xiv + 269. (New York: The Macmillan Co., 1929.) 12*s.* 6*d.* net.

(2) *Food Values in Practice: Simple Guidance in Diet Planning and Cookery.* By Ethel M. Dobbs. Pp. xvi + 240. (London: University of London Press, Ltd., 1929.) 4*s.* net.

(3) *Properties of Food: a Practical Text-Book for Teachers of Domestic Science.* By W. M. Clifford and Prof. W. H. Mottram. Pp. 128. (London: University of London Press, Ltd., 1929.). 2*s.* 6*d.*

(4) *Food, Health, Vitamins.* Being a new edition of "Food and Health". By Prof. R. H. A. Plimmer and Violet G Plimmer. New edition. Pp. viii + 120. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1929.) 3*s.*; paper, 2*s.*

THE importance of a proper diet for healthy living is now well realised by medical men and health workers, but is not always appreciated by the general population: even with such knowledge, the devising of a suitable dietary within the means of the more poorly paid members of the community is not always easy. Again, it is essential nowadays that all those responsible for feeding the inmates of institutions, hospitals, schools, etc., should arrange their diets on scientific principles. To supply dieticians and others interested with the requisite knowledge, numbers of manuals have been written, varying from the scientific treatise on nutrition to the primer suitable for the lay reader. Several such works have been published in recent years, covering a part of this possible range in depth of scientific knowledge, and four are now before us.

(1) Dr. Rose's handbook is intended for the dietician and provides the information necessary for the planning of dietaries for people of different ages and either sex. A brief account of the composition and uses of foods is followed by examples of the methods of calculating the food requirements and specimen dietaries. Height-weight-age tables are supplied, and, forming the bulk of the book, tables of the composition, including calorie value, of all the common foodstuffs.

(2) Dr. Dobbs's book covers part of the same ground, but in a more elementary manner: it is intended for the enlightened housewife and health worker rather than the dietician. Simple dietary calculations are included; methods of cooking are described in detail; nearly half the book is devoted to recipes for dishes suitable for the normal household, in fever and convalescence, in pregnancy, and for the constipated, the fat and the thin.

(3) Dr. Clifford and Prof. Mottram have written their little book for teachers of domestic science; simple chemical tests for the different foodstuffs are described, special attention being devoted to the demonstration of the properties of foods with only the minimum of chemical apparatus. Experiments are given to show how food is digested and what happens to it when it is cooked, and a chapter is devoted to the calculation of calorie and other values of food from tables. The chemical tests described show no little ingenuity and can be carried out by anyone possessed of only an elementary knowledge of chemistry.

(4) Prof. and Mrs. Plimmer's book has now reached its fourth edition; its outlook is different from that of those previously referred to, since the necessity for an adequate vitamin intake is especially emphasised. At the same time, the essentials of a complete dietary are fully described and two simple balanced diets at minimum cost are given: an extra chapter on diet in special cases has been added. The fact that four editions have appeared in five years indicates that this small work fulfils a real want; and opportunity is taken to bring the text up-to-date, since the subject dealt with is one in which our knowledge is advancing rapidly in many directions.

Experiments on Atomic Physics.

Electron Physics. By Dr. J. Barton Hoag. Pp. ix + 208. (London: Chapman and Hall, Ltd., 1930.) 15*s.* net.

THIS book is an account of a laboratory course on modern physics which has been developed by the author and Prof. A. J. Dempster at the University of Chicago. The experiments to be performed are twenty-three in number, nine of which illustrate properties of radioactive bodies, and the remainder properties of electrons and ions, and some of their applications. With each group of experiments there is an up-to-date summary of the theory and standard results of that branch of the subject. There are three excellent appendices on vacuum technique, and two on the use of electrometers and electroscopes, a collection of problems, and some tables of atomic constants.

Most of the experiments described are familiar, but several will be new to many teaching laboratories, in particular the determination of the charge of an electron by the oil-drop method, the use of

the photoelectric cell, and two methods for finding the ratio of charge to mass for an electron by magnetic bending of cathode rays. The general standard is such that the book could also quite well have contained the measurement of e/m for an electron by the Zeeman effect, the use of an X-ray spectrometer, and the photography of trails of ionising particles with a Wilson cloud chamber.

In a sense, however, the actual contents are only of secondary importance. The publication of a book of this type is in itself effectively a statement that it is just as desirable, and possible, for students to carry out a connected set of experiments on the properties of atoms and electrons, as it is for them to do experiments in sound, or heat, or geometrical optics, or in any of the better established branches of physics. After all, to advance no other arguments, this newer work bears very closely on everyday life, and the equipment required to teach it is not in the end more elaborate than much in current use. The main difficulty comes in deciding what is to be thrown out to make room for it in a course necessarily limited to, say, three years.

On one important point the judgment of the author may be challenged. He states in his preface that "The book has been prepared for the student who has had one year of college physics or its equivalent". Experience in English laboratories suggests that work of this type might not be appreciated by a student in his second year, and that he would quite possibly fail to grasp the significance of what he was doing; in his final year, however, it would be of the utmost value. K. G. E.

History of Determinants.

Contributions to the History of Determinants, 1900–1920. By Sir Thomas Muir. Pp. xxiv + 408. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1930.) 30*s.* net.

IT is almost exactly half a century since a forty-page "List of Writings on Determinants", compiled by Thomas Muir, was published in the *Quarterly Journal of Mathematics*, marking the inception of an attempt to provide a complete history of determinants, up to 1900 if possible. How the attempt was crowned with success forty-two years later, by the publication of vol. 4 in 1923, is common knowledge. The work we now review goes beyond the original intention; when supplemented by several extraneous articles cited, in the *Proc. Roy. Soc. Edin.* and the *Trans. Roy. Soc. S. Africa*, it constitutes vol. 5 and brings the history up to yesterday.

In a characteristically unassuming preface Sir Thomas briefly alludes to the vicissitudes his self-imposed 'contract' underwent, and it needs but slight imagination to amplify his modest understatements and to conceive the real seriousness of the hindrances encountered: the absorption in administrative educational work in South Africa, the remoteness of European reference libraries, the perturbations of two wars. By 1915 the work had been brought only as far as vol. 2, and retirement at that date from the position of Superintendent-General of Education meant for the author, at seventy years of age, no tranquil retrospect but rather intensified activity. The achievement of the last fifteen years, with its fruit, vols. 3, 4, and 5, indicates a sustained vitality which evokes astonished admiration.

The present book is not so large as vol. 4, since eight chapters, each self-complete, are excluded and referred to separately, as we have mentioned. The sources quoted for these are, of course, readily accessible to all workers; and the restriction brings the book down to a convenient size for handling. The printing, on smooth white paper, is beautiful: and a scrutiny of hundreds of formulæ failed to disclose a single fault.

Concerning the arrangement, subjects, and style, little can be said which has not already been handsomely said by reviewers of earlier volumes. The various heads—determinants in general, axisymmetric, alternant, compound, and so on—fall une review in the self-contained chapters and sequence we now expect The style has Roman qualities of solidity, clarity, and conciseness, and the comments are as impartial and as illuminating as ever; a typical example is the summary (pp. 187-190) of a paper by Giambelli. The extent of the author's own personal contributions during the period may be gauged by the number of papers against his name in the index, 109, as compared with 108 in vol. 4.

A feature of outstanding value is the concluding 36-page subject-index of all five volumes. The inclusion of this cannot be too highly commended. With such wealth of reference as this provides, it is no longer, surely, a venial offence for writers to publish rediscoveries, as has so often happened before.

Nothing remains but to congratulate the distinguished author on these latest rewards of his long tenacity. The work is classic; if there exists anywhere a more detailed and comprehensive history of any branch of theoretical knowledge, one would be interested to hear of it. Yet one hesitates to use phrases like "the culmination of the work of a lifetime"; the energetic author is only eighty-six, and may yet bring it up to 1930! A. C. A.

Our Bookshelf.

The Scientific Achievements of Sir Humphry Davy. By Joshua C. Gregory. Pp. viii + 144. (London: Oxford University Press, 1930.) 6s. net.

It is always interesting to attempt to trace the origin of scientific work, and although the results are liable to error, they provide a key to much that otherwise would be obscure. In this book Mr. Gregory has tried to show how many of Davy's researches and speculations may have had some relation to the scientific knowledge of his day, and in this way the progress of Davy's work is seen to follow a course which makes it more intelligible to us at the present time. The book is more concerned with the scientific achievements than with the personal character of the great chemist, and although Mr. Gregory writes sympathetically, he has not raised some of the questions which have perhaps received too much attention in the past. Davy suffered by too much success on his own part and from too much sensitiveness on the part of others.

Apart from giving an excellent and clear account of Davy's researches, the book provides a useful picture of the state of chemistry in general at the beginning of the nineteenth century, when the theory of phlogiston still lingered in the minds of chemists even after they had been forced by experimental facts to abandon it as a working hypothesis. The new instrument of research, the voltaic pile, had just come into being, and in Davy's hands it opened a splendid chapter in the great story of chemistry. The relations between Davy and Dalton are discussed in an interesting manner, and the strange reluctance of Davy to use the hypothesis of atoms, a reluctance shared to the full by Faraday, is mentioned. At the same time, Davy was able to arrive at the correct formula for water, H_2O, whilst Dalton remained faithful to the simple HO which served chemists for so many years afterwards.

Mr. Gregory's book is one which can be recommended. It is not too long, but it contains a large amount of interesting materials. It is a pity that the appearance of the text has often been spoiled by the use of large capitals in the equations.

Handbuch der Experimentalphysik. Herausgegeben von W. Wien und F. Harms. Unter Mitarbeit von H. Lenz. Band 4: *Hydro- und Aero-Dynamik.* Teil 3: *Technische Anwendungen.* Herausgegeben von Ludwig Schiller. Bearbeitet von O. v. Eberhard, R. Emden, O. Flachsbart, W. Gaede, L. Hopf, F. Horn, W. Klemperer, W. Spannhake. Pp. x + 557. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1930.) 55 gold marks.

In this survey of the technique of hydro- and aero-dynamics, the editor has succeeded in attracting to his service a strong body of experts, who bring to it a long and intensive experience of their subject. The section on model ship tests is written by F. Horn, balloons by R. Emden, airship tests by W. Klemperer of the United States, experimental full scale flight by L. Hopf, turbines by W. Spannhake, air screws by O. Flachsbart, air pumps by W. Gaede, and ballistics by O. v. Eberhard, all well-known names in their respective fields.

The general plan that has been adopted in each section appears to be to give a critically connected non-mathematical account of the subject, with exceedingly useful and up-to-date details of experiments that have been conducted to test out the various crucial points. Diagrams indicate very clearly the lay-out of the experimental plant and the type of apparatus in use in the research institutions in different countries of the world.

As is to be expected from a work of this nature produced almost entirely by German writers, the sections deal very largely with the researches conducted in that country. It is a tribute, however, to workers in Great Britain that several of the sections enter very fully into the details of experiments conducted in British institutions, notably at the Royal Aircraft Establishment and at Teddington. The work is exceedingly rich in references. Incidentally, it is interesting to note the tendency in all countries for the centres of research activity to concentrate in the State-supported institutions.

The Subject Index to Periodicals, 1928. Issued by the Library Association. Pp. viii + 326. (London: The Library Association, 1930.) 70s. net.

We congratulate the Library Association on the publication of the "Subject Index to Periodicals" for the year 1928. The first volume of this valuable series was for the year 1915, so that these subject indexes now enter upon the sixteenth year of their existence. It has, however, not yet been found possible to issue the volumes for 1923, 1924, and 1925, although these volumes are in preparation.

The present volume, like its predecessors for 1926 and 1927, is arranged alphabetically by subjects, the headings being chosen from the alphabetical subject headings of the Library of Congress, with modifications and additions to suit British practice. When the titles of articles do not sufficiently indicate their contents, brief annotations are given. Under each heading the articles are arranged alphabetically by the author's name.

The subjects indexed cover a wide field, but magazine verse and fiction are not included.

The periodicals indexed are, for the most part, those published in the English language, but a certain number of journals in the French, German, Dutch, and Italian languages are included. The general editor, E. E. G. Tucker, has been ably assisted by the librarians of the chief public libraries in Great Britain.

Although the subjects indexed are by no means confined to science, yet science is so well represented among the headings that this subject index will be found to be a very useful work of reference in any scientific library. Important papers sometimes appear in periodicals where they stand a chance of being quite overlooked unless they are traced by reference to a "Subject Index to Periodicals".

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Anticipation of Wegener's Hypothesis.

THE question of the bodily displacement of continental masses on the earth's surface has been the subject of considerable discussion among geologists and geophysicists in recent years.

When first I heard this referred to as 'Wegener's Hypothesis', my memory went back to my schooldays and to a popular book on science which I then possessed entitled "The Playbook of Metals", by J. H. Pepper, the inventor of the optical illusion known as 'Pepper's Ghost'. The subject having recently come up again in the course of conversation, I took the opportunity of consulting the Library of the University of Cambridge, where I was fortunate enough to find a copy of this work, dated 1861. In it are to be found two diagrams, photographic reproductions of which were kindly made for me by Mr. W. H. Hayles, of the Cavendish Laboratory (Figs. 1 and 2). Pepper states that these diagrams are from a book entitled "La Création et ses mystères dévoilés", by A. Snider. It was necessary for me to go to the British Museum Library to find a copy of this latter work, the date of which I ascertained to be 1858.

It is interesting to compare these dates with those given by Prof. Wegener in his book, "Die Entstehung der Kontinente und Ozeane", where the following passage occurs (see p. 3):

"Die erste Idee der Kontinentalverschiebungen kam mir im Jahre 1910 bei der Betrachtung der Weltkarte unter dem unmittelbaren Eindruck von der Kongruenz der atlantischen Küsten, ich liess sie aber zunächst unbeachtet, weil ich sie für unwahrscheinlich hielt. Im Herbst 1911 wurde ich mit den mir bisher unbekannten paläontologischen Ergebnissen über die frühere Landverbindung zwischen Brasilien und Afrika durch ein Sammelreferat bekannt, das mir durch Zufall in die Hände fiel. Dies veranlasste mich, eine zunächst flüchtige Durchmusterung der für die Frage in Betracht kommenden Forschungsergebnisse auf geologischem und paläontologischem Gebiet vorzunehmen, wobei sich sogleich so wichtige Bestätigungen ergaben dass die Überzeugung von der grundsätzlichen Richtigkeit bei mir Wurzel schlug. Am 6. Januar 1912 trat ich zum erstenmal mit der Idee in einem Vortrag in der Geologischen Vereinigung in Frankfurt a. M. hervor, der betitelt war 'Die Herausbildung der Grossformen der Erdrinde (Kontinente und Ozeane) auf geophysikalischer Grundlage'. Diesem Vortrag folgte am 10. Januar ein zweiter über 'Horizontalverschiebungen der Kontinente' in der Ges. z. Beförd. d. gesamten Naturwiss. zu Marburg. Im gleichen Jahre 1912 folgten auch die beiden ersten Veröffentlichungen."

We thus see that the hypothesis of continental displacement had been put forward a full half-century before it first occurred to Prof. Wegener.

FIG. 1.—The earth before separation (Snider's diagram).

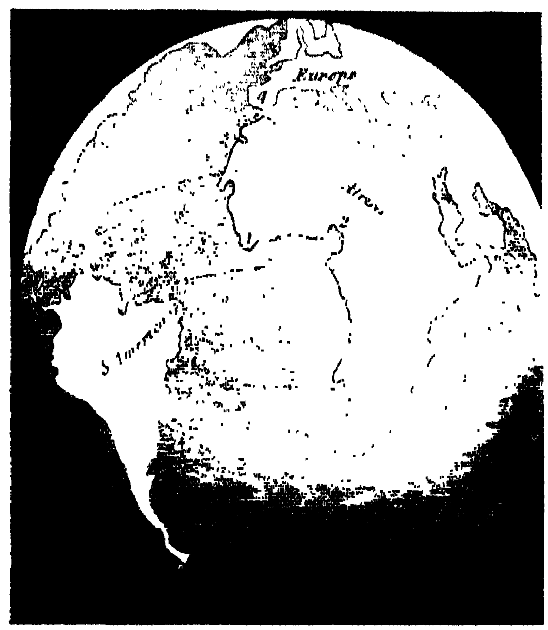

FIG. 2.—The earth after the separation (Snider's diagram).

On comparison of Snider's diagrams with those of Prof. Wegener, the essential similarity will at once be apparent; the main difference in detail being that Snider puts the junction of Australia with Africa somewhat farther north than does Prof. Wegener.

From the fact that it should have been mentioned in a popular book on science like Pepper's "Playbook of Metals", one would infer that the hypothesis must have been well known about this period, and it is highly probable that the pros and cons of it were pretty well discussed by scientific men.

I freely admit, from what I have seen of Snider's book, that I do not think it would be treated very seriously as a whole by men of science nowadays; but I need scarcely point out that a question of fact is quite distinct from any explanation thereof which may be put forward, and it seems quite clear that the hypothesis of continental displacement (be it true or false) dates at least so far back as 1858, if, indeed, it may not be possible to trace it still further. As regards evidence in favour, or otherwise, of the hypothesis (by whatever name it be called), we must still, of course, turn to the work of Prof. Wegener and other writers who have studied the subject in its various aspects.

ALFRED A. ROBB.

Cambridge, Oct. 24.

Polarisation of Electrons.

DR. RUPP[1] finds that if electrons of 80 kilovolts energy are reflected in succession from two gold surfaces at an angle of about one-third of a degree, there is a twelve per cent. difference in the intensity of the twice reflected beam according as the two deviations are in the same or opposite directions. I have attempted to repeat this result for electrons scattered in succession through two thin gold films. The films were thin enough to give good ring patterns and the method is to measure photometrically the diffraction pattern formed by the twice scattered beam. The result is negative. Eight plates were taken, each with two exposures; the mean difference between the two sides for seven of these plates was 1 per cent. Of the individual pairs of readings, half differed by less than 5 per cent on the two sides, which corresponds to about 2 per cent probable error on the mean of the seven plates. The eighth plate gave a mean effect of 20 per cent. in the reverse direction to that found by Rupp. I am unable to account for this plate, and as I have left Aberdeen, where the experimental work was done, I cannot attempt to repeat it. It is possibly due to uneven development.

In some cases the rays selected for the second scattering formed part of one of the diffraction rings formed by the scattering in the first film. In other cases they came from the part of this pattern between the rings. Since the regularly diffracted electrons are always in a minority, the polarisation might be greater than suggested by the above figures if it were limited to these electrons, but there is no sign of such an effect. The angles of scattering were of the order of 2°; the mean energy of the electrons was 65 kilovolts. The experiment is in agreement with the view that the detection of polarisation by such means is only possible with large angles of scattering. Since making the experiment I have seen a paper by Kirchner,[2] in which he mentions that he has satisfied himself that the effect, if any, is less than 10 per cent.

Heredity and Predestination.

SOME of us are wont to ascribe a super-papal infallibility to the editorial notes in NATURE, and it is, therefore, with much diffidence that I suggest a certain misunderstanding in the issue of Nov. 15, p. 781, as to my Lloyd Roberts Lecture. The place of moral values in modern arguments for theism is so fundamental that possibly space can be found for a few sentences which may stimulate biological experts to consider afresh the relation of evil to the evolutionary process.

Mutations, I stated, appear to be the raw material of evolution: and they seem to be devoid of any ethical character whatever. Changes in the genes—call them simply inheritance factors if their localisation in the chromosomes is doubted—are as near as we can at present get to creative activity: but in such changes we can discover no moral quality. Good and evil, as judged by our standards, are equally likely to arise in the variations associated with heredity.

The note in NATURE says that the 'evil and good' of my argument "are simply adjustment or maladjustment to environment". I would that it were so, for then the theologian's difficulties would be at an end. All that is good would flourish because adapted to its environment. The evil would disappear under the operation of natural selection. We could then, indeed, affirm with Pippa, "God's in His heaven: all's right with the world". Huxley's war between man and the cosmic process would be unnecessary.

Unfortunately, however, the loathsome parasite is a result of the integration of mutations: it is both an exquisite example of adaptation to environment and ethically revolting. Civilised nations, as I emphasised, have of late been creating an environment to which the mental deficient can happily adapt himself: humane principles and social degeneration are thus conjoined. None the less—and here is the puzzle over which I ask biologists to ponder—out of the evolutionary process has come the progress which has led to man with his spiritual consciousness and moral loyalties. I reached the perplexing conclusion that, if we accept the moral argument for ethical theism, we must find Divine activity, albeit elusively, in the environment and not in the genetic changes through which apparently the creative process works. But, as I told my Manchester hearers, I was thinking aloud. My conclusion cannot claim the merit (or demerit) of orthodoxy; and I am willing to be converted to any other explanation for which better arguments can be adduced.

May I add, though it is a subsidiary matter, that I do not personally accept the notion that mutations "are causeless in the sense of being entirely fortuitous". It is part of my faith that the universe is rational for man. Belief in the possibility of successful scientific investigation rests upon such a faith. That faith has its difficulties: as we know, there are those who hold that science will always be limited to regions upon which man can impose his own sense of order. But, if the larger faith be true, the progress of research should in due course give us the 'causes' of mutations or, more accurately, sequences of which they are the end terms. But such sequences, as Hume pointed out long ago, will not lead us to efficient causation. For that we need some metaphysical postulate.

E. W. BIRMINGHAM.

Bishop's Croft, Birmingham,
Nov. 15.

THE letter of Dr. Barnes raises two difficulties in our mind. 'Good' and 'evil', as applied to the organisms which in his lecture he grouped as "animals and insects", and on which he relies for his genetic data, can only mean relative adjustment or mal-adjustment to environment, for the biological end of a creature is to multiply its kind. A parasite is biologically evil because it has renounced the power of initiative, replacing it by dependence upon the success of its host, and because the more successful the parasite is, the more precarious its existence as a species becomes. The 'good and evil' of humanity, in so far as they are conventions sanctioned by custom or law, are acquired characters and have nothing to do, if Dr. Barnes is right about the non-heritability of acquired characters, with inheritance factors, but biologically conventions may be good or evil, as they encourage or discourage the best continuance of the race.

Feeble-mindedness is a mal-adjustment which in Nature would meet its own fate, and the morality which protects and encourages feeble-mindedness is also a mal-adjustment which also will meet its fate.

The second difficulty is Dr. Barnes's firm belief in the 'non-morality' or fortuitousness of mutations. It is an uncertain hypothesis, unacceptable to many biologists, yet on it the argument of the Lloyd Roberts Lecture was based. Our notion is that environment may be more than a mere eliminator, but any further power it may exercise must depend upon the response of the organism. THE WRITER OF THE NOTE.

Agricultural Field Experiments.

IN the article with the above title which appears in NATURE of Oct. 25, p. 667, it is stated:

"Beaven's half drill strip method is described, but without pointing out its two serious but remediable defects: that the continued use of one half of the drill for one variety, and of the other half for the variety with which it is to be compared, may introduce a constant difference the magnitude of which cannot be estimated; and that the regular alternation of strips of the two varieties does not permit of a valid estimate of experimental error."

I submit that these defects are more theoretical than practical, and that any modification of practice in the application of the method, such as changing over seed boxes, would be a retrograde step.

To take the first, there are three possible ways in which one half of a drill may differ from the other:

(1) It may cover a wider breadth of ground; this would doubtless have an appreciable effect, but it would be detected and allowed for by the routine measurements taken across the stubble.

(2) The coulters may be less evenly spaced than those of the other, and

(3) Less seed may be drilled from it than from the other.

Now, cereal crops are wonderfully independent of the amount of seed sown. I have in mind two chess-board experiments, in one of which half the area was sown with seed 1 in. apart instead of the usual 2 in., and in the other, the rows in half the experiment were 3 in. apart instead of 6 in. In each case the heavier seeding only resulted in a gain of about 3 per cent, and it is not to be expected that such slight irregularities as occur between the two halves of a drill would have any measurable effect.

The second defect, owing to the peculiar shape of the half-drill strip, would only exist if the experiment were to be sited so that some periodic variation existed across the breadth of the drills: otherwise randomness is supplied by the soil. By taking care that the experiment is drilled across ploughman's 'lands', if they exist, and by bearing in mind the history of the last few crops, this danger can be avoided.

The pairs of strips fall naturally into two sets according as one or other variety is on the right hand, and in an analysis of the variance of the difference between varieties, one degree of freedom is taken up by these two sets. The estimate of the experimental error arrived at in this way is perfectly valid, provided the above precautions have been taken in siting the experiment.

It would be a pity to interfere unnecessarily with the simplicity of this very efficient method of conducting field trials.

STUDENT.

I FEEL that 'Student' under-estimates the importance of differences in the two halves of a seed-drill. I have repeatedly found significant differences between adjacent rows in respect of such characters as plant-height, number of tillers per unit length of row, and, finally, yield per unit length of row. This is sufficiently marked to make it definitely an advantage, for precise observations, to divide the observational unit of a metre-length of row into two half-metres, end to end but on adjoining rows. I suspect that depth of sowing (a factor which 'Student' does not mention) and amount per unit length play the important part in determining this individuality of the row. The results of a small-plot experiment which I examined recently showed that the yield of wheat per unit area was unaffected by changes in spacing, but was considerably lessened by increased depth of sowing, as also by decreased amount of seed per unit length of row. The number of rows in a 'half-drill strip' is small, so that a considerable difference may result from these causes, even with random distribution amongst the coulters of depth and amount of delivery. There is likely, however, to be a steady gradation in depth of delivery as one passes from one side of the drill to the other, and this would more certainly constitute a 'serious defect' in the half drill strip method.

'Student' is satisfied with the validity of the estimate of error, provided care is taken to drill across ploughman's 'lands'. There was an interesting series of uniformity trials carried out at the Danish station at Aaslev, in which an apparently uniform field revealed a periodicity in yield, of half-wave-length almost coincident with the width of the plots. Had this been a varietal trial, and had the half-drill strip method been used, the experimenters might have been sadly misled!

The method loses only slightly in simplicity and gains considerably in value if modified in one of the following two ways, as R. A. Fisher has pointed out. If there is any possibility of a steady fertility gradient at right angles to the length of the strips, the arrangement should be a set of 'sandwiches', but it should be decided at random for each whether variety *A* or variety *B* should occupy the two middle strips: if it is certain that no such gradient exists, then the more satisfactory arrangement is to take *pairs* of strips, deciding, again at random, whether *A* shall be on the left-hand or the right hand strip. The former arrangement gives as many degrees of freedom as there are sandwiches; and, for the same number of strips, the latter gives twice as many degrees of freedom. The strips should all be drilled with the same half-drill.

THE WRITER OF THE ARTICLE.

Relationship of the Oat Smuts.

TWO species of smuts—*Ustilago avenæ* and *U. levis*—occur commonly on cultivated oats. They differ from one another in the character of their spores and in the appearance of the spore masses produced on their host plants. The spores of *U. avenæ* are minutely echinulate; those of *U. levis* smooth. *U. avenæ* usually destroys the florets of the host plant, giving them a blackish, powdery appearance; *U. levis* causes less injury to the inflorescence and at maturity its spores may be entirely concealed by the glumes.

During the past year we have been investigating experimentally the relationship between the two species. Spores of the loose and covered smuts have been germinated singly in hanging drops, and their sporidia removed one by one and cultured separately on artificial media.

Young oat seedlings were inoculated with the following cultures or combinations of cultures: (1) Monosporidial cultures of *U. avenæ* used singly and in pairs. (2) Monosporidial cultures of *U. levis* used singly and in pairs. (3) Pairs of cultures, each one made by mixing together a monosporidial culture of *U. avenæ* with one of *U. levis*.

The seedlings were grown to maturity in the greenhouse, and observations were made as to the appearance of the smutted heads and the kind of spores borne in them. The results of the inoculations are of considerable interest and may be summarised briefly as follows:

(1) Plants inoculated with a single monosporidial culture of *U. avenæ* or *U. levis* did not produce smutted heads.

(2) Plants inoculated with two monosporidial cultures of opposite sex produced smutted heads. If the two cultures were of *U. avenæ* the infected

heads were 'loose' in appearance and their spores echinulate; if of *U. levis* the heads were 'covered' in appearance and their spores smooth; if one of the cultures was of *U. avenae* and the other of *U. levis* the infected heads were somewhat variable in appearance, but upon close examination they proved to be of the 'loose' type, and their spores were echinulate.

(3) The sporidia of *U. avenae*, like those of *U. levis*, are of two kinds, (+) and (−); the sporidia of one species mate without difficulty with sexually opposite sporidia of the other species.

These results indicate that *U. avenae* and *U. levis* are genetically distinct with respect to the characters by which they are differentiated, but the ease with which crosses can be made between them suggests that they are closely related species.

A full report of the investigation is being prepared for publication.

Synthesis of a Methoxyketose.

A 5-METHOXYKETOSE has been prepared by the condensation of dioxyacetone, $CH_2OH.CO.CH_2OH$, and α-methoxyglyceric aldehyde, $CH_2OH.CH(OCH_3).CHO$. The method of synthesis is proof of the position of the methoxyl group and such a structure cannot form a furan ring.

Pure dioxyacetone was obtained from nitromethane by the method of Henry and Piloty. Neither α-methoxyglyceric aldehyde nor its acetal had been prepared but the latter was obtained by methylating α-chlor-β-oxypropiondiethylacetal with sodium methylate, α-chlor-β-oxypropionacetal being formed from acrolein through the intermediary of β-chlorpropionacetal and acroleinacetal by a modification of the methods described by Wohl and Witzemann. The required acetal was obtained as a colourless liquid distilling at 100°-102° C./6mm. This was readily hydrolysed by dilute mineral acids and the aldehyde produced was converted into the bromphenylhydrazone derivative and into the condensation product with phloroglucinol. The preparation of these derivatives and the analysis of the acetal proved the identity of the aldehyde.

The conditions used by Fischer in his synthesis of α-acrose were modified to suit the condensation of dioxyacetone and α-methoxyglyceric aldehyde and the optimum results were obtained by allowing a 5 per cent aqueous solution containing 0·25 per cent of barium hydroxide to stand at room temperature for a period of three weeks.

Dioxyacetone is in equilibrium in aqueous solution with glyceric aldehyde, and hence, theoretically, it should be possible to obtain as a result of this condensation four inactive 5-monomethoxyketoses, the corresponding eight inactive 5-monomethoxyaldoses, and the twelve racemic forms of the non-methylated hexoses. The number of possible osazones is only eight and it was not considered likely that the non-methylated osazones would be formed in any quantity. Further, from analogy with the work of Fischer and Schmidt it was expected that the bulk of the product would consist of a single racemic form. These expectations were realised, but it may be noted that for the purpose in hand the actual identity of the substance produced was immaterial, the aim being to synthesise a ketose which could not possess a furan structure.

Treatment of the reaction mixture with phenylhydrazine under the usual conditions gave an impure, crystalline substance and a tarry mass. The former proved to be acetylphenylhydrazine, whilst from the latter a mixture of osazones was isolated with considerable difficulty. Repeated fractional crystallisations from ethyl acetate gave two main fractions of osazones, a larger fraction melting at 183° C. and a smaller fraction melting at 130° C. These gave analytical figures corresponding to a pure monomethoxyhexosazone. From analogy with the work of Fischer on α-acrose and on a consideration of the melting points of the known methylated and non-methylated osazones the former product was considered to be inactive 5-monomethoxyfructosazone and the latter inactive 5-monomethoxysorbosazone.

The monomethoxyhexosazone (m.p. 183°), of which 35 grams were obtained (from 5600 grams of acrolein), was converted through the osone into the corresponding monomethoxyketose by a modification of Fischer's method. Five grams of a crystalline material melting at 80°-85° C. were obtained which gave analytical figures corresponding to a pure monomethoxyhexose. Treatment at room temperature with methyl alcohol containing 1 per cent HCl showed that fructoside formation was complete only after 48 hours. This was evidence in favour of a sugar which cannot exist in the γ-form since the formation of γ-methylfructoside is complete after one hour. The monomethoxymethylhexoside was methylated by treatment with methyl sulphate followed by two successive methylations with Purdie's reagents. Towards alkaline permanganate this tetramethoxymethylhexoside behaved as a normal sugar derivative and the rate of hydrolysis also corresponded to that of normal tetramethoxymethylfructoside. Hydrolysis of the synthesised hexoside was complete on refluxing with 3 per cent aqueous HCl for three hours and the product was isolated as a syrup in the usual way. From this syrup tabular crystals were obtained by extraction with light petroleum which, after repeated crystallisations, melted at 95°-96° C. There was no depression of melting point on mixing with an authentic specimen of normal tetramethoxyfructose.

Nitric acid oxidation gave a trimethyl lactol acid which on further oxidation with alkaline permanganate yielded a trimethylarabonolactone. The curve of apparent specific conductivity plotted against time obtained by observations during the hydrolysis of the lactone derived from the synthesised tetramethoxyhexose was almost identical with the curve given under similar conditions by the lactone derived from normal tetramethoxyfructose but was sharply differentiated from that given by the lactone corresponding to tetramethoxy-γ-fructose.

From these experiments it is shown that the synthesised 5-methoxyhexose and its derivatives have exactly similar properties to those of the methylated derivatives of normal fructose, and that the synthesised hexose was in fact the racemic form of 5-monomethoxyfructose. Since the methoxyhexose produced by condensation could not possess a 5-atom ring, and of the other possible ring structures the pyranose is considered to be the most likely, this evidence, obtained from a field hitherto unexploited, proves conclusively that normal fructose and its derivatives cannot possess a furanose structure and lends support to the accepted pyranose constitution.

A parallel experiment is in progress with the object of synthesising a 6-methoxyhexose.

Double Refracting Structure of 'Corex' Glass.

SOME years ago I found that silica glass showed a doubly refracting structure (*Proc. Roy. Soc.*, A, vol. 98, p. 284; 1920. Also *Proc. Optical Convention*, Part 1, p. 41; 1926). This structure is quite distinct from any due to bad annealing, and seems kindred to the 'liquid crystals' of Lehmann. Nothing of the kind could be found in the ordinary glasses consisting of silica with metallic oxides.

I now find that the ultra-violet transmitting 'Corex' glass of the Corning Co. shows a similar structure. This glass is said to consist in the main of calcium phosphate, though I have not seen an analysis. The subject evidently requires detailed examination, which I hope to make as opportunity allows.

Energy Levels of Atoms in an Electric Field.

ISHIDA has recently given clear experimental evidence that Stark levels with equal m values do not intersect (*Sci. Pap., I.P.C.R.*, Tokyo, No. 260; 1930). With increasing field, the levels approach to a limiting separation and then recede. This feature of the investigation was limited to levels with equal m but different n values.

I now notice on a plate which has been published (Neon; Foster and Rowles, *Proc. Roy. Soc.*, vol. 123, 80; 1929) a good illustration of this point for the case where the levels have the same principal quantum number. The diffuse line $2p_9 - 7d'_4$ approaches the sharp line $2p_9 - 7s_5$ as the electric field increases (Fig. 1). When the separation (25 cm.$^{-1}$) is but a

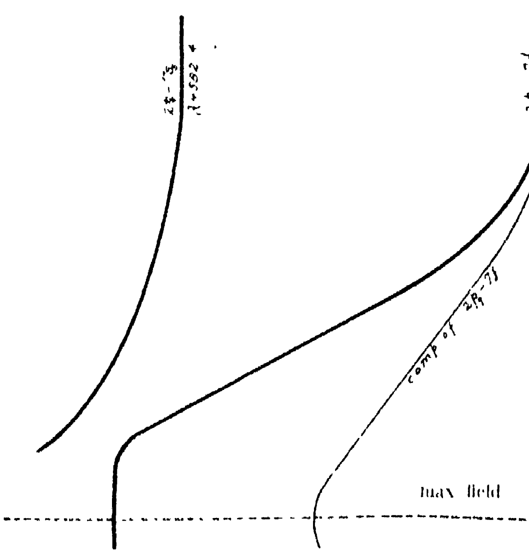

FIG. 1.

raction of the almost constant separation observed or the other components with (initial) $m_i = 0$, it turns bruptly and retains constant displacement up to maximum external field.

In the paper referred to, Ishida reproduces some remarkably fine plates which give strong support to the theory of the Stark effect in helium (Foster, *Proc. Roy. Soc.*, vol. 117, p. 137; 1927). On two points, however, his interpretations lead him to very striking conclusions at variance with the theory and with earlier experiments (Foster, *Proc. Roy. Soc.*, vol. 114, p. 47; 1927). I should like to suggest views which (if correct) will place the new results in harmony with previous work.

The conclusions reached by Ishida are (1) that the selection rule $\Delta m = 0, \pm 1$ is broken, and (2) that hitherto unknown series lines have been discovered in the helium spectrum. The selection rule is apparently broken by the appearance of a few weak π components having the same wave-length as corresponding members of the strongest group of σ components ($m = 2$ in initial state). This is not an effect due to the larger fields he employs, since in his photographs it persists in moderate fields. On any one plate it is found only where the corresponding σ component has extraordinary strength, yet it fails to appear on the plate showing the intense yellow line λ5876. This irregularity attracts one to the possible view that an imperfect adjustment of the double-image prism with reference to the axis of the Lo Surdo tube may account for all that has been observed, and allow the selection rule to apply here as elsewhere. But even with this adjustment correctly made, this phenomenon has been observed, and attributed to an occasional confusion of the fields in a Lo Surdo source (Foster, *Astrophys. Jour.*, vol. 62, p. 235; 1925).

The second point is concerned with π components which vanish or become very weak as they pass under the zero field position of the $P - P$ combination line (or $S - S$ or $p - p$ or $s - s$, as the case may be) of the group to which they belong. This phenomenon has been observed in many experiments (Foster, *Phys. Rev.*, vol. 23, p. 667; 1924; *Jour. Frank. Inst.*, vol. 209, p. 585; 1930). Nevertheless, Ishida regards the lines as entirely new at the point of reappearance. One can understand that the sloping lines are cut off vertically, and doubtless appear to point to zero field positions near those of the $P - P$ lines. But as Ishida observes, there are no terms in the well-known normal helium spectrum which can account for such origins. It is doubly difficult, therefore, to deny the theory which on this point has already received adequate experimental support.

Determination of the Abundance Ratios of Isotopes from Band Spectra.

I RECENTLY reported an intensity anomaly in the isotopic bands of boron monoxide (NATURE, Aug. 9, p. 203), which showed that the intensity ratio of isotopic bands does not always give directly the relative abundance of the isotopes. The following is an account of the determination of the correction to be made in order to obtain the relative abundance from the intensity ratio, and is an abstract from a dissertation presented to the University of Utrecht.

The intensities of the heads of all the bands of the $B^{11}O$ β-system which appear on plates with exposures of four hours have been measured; variations of plate sensitivity were corrected for by comparison with a lamp the spectral energy distribution of which was known. The intensity of each band was then divided by ν^4, ν being the frequency of the band in question, in order to obtain the square of the amplitude of the virtual oscillators, since it is the latter quantity which is additive. By adding up the values of I/ν^4 for all the bands having a common v', a figure was obtained which gave a measure of the number of $B^{11}O$ molecules in the v' state. This was done for the different v'' progressions, and so the number of molecules in the different v' states was determined. The graph (Fig. 1) shows $f(E'_v)$, the number of $B^{11}O$ molecules in these states, plotted as a function of the vibrational energy E'_v.

If it be now assumed that the same function holds for $B^{10}O$, then the ordinates drawn through the energy values of the vibrational states of $B^{10}O$ will give the number of those molecules in the various v' states;

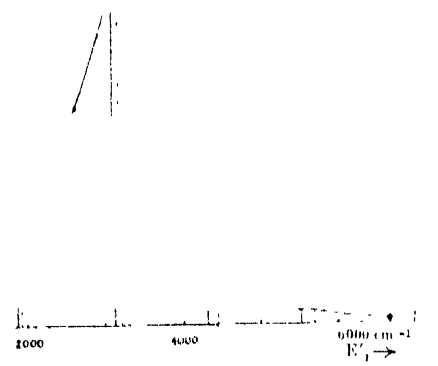

FIG. 1.

these states are shown by the dotted lines. It is evident that the isotope intensity ratio for bands from the v' 3 state will be considerably higher than that for the bands from lower v' states. The table

Isotope ratio .	3·63	3·50	3·61	3·66	3·68	3·61

Mean Isotope Ratio = 3·63 ± 0 02.
Corresponding Atomic Weight (correcting for O^{17} and O^{18}) = 10 791.

shows the corrections $f(E'_v)/f(E'_1)$ obtained from this curve by which the measured intensity ratios must be divided in order to obtain the real relative abundance of the isotopes. More complete data (which refer to Chilian boron) are given than were contained in the previous communication, and a correction for change in plate sensitivity with wave-length has been made. The very good agreement of the corrected isotope abundances determined from different bands may be pointed out.

In a recent letter (NATURE, Oct. 25, p. 649), Stenvinkel has given an explanation of the high ratio for the 3-7 band, based on the supposition that Boltzmann distribution holds for the lower electronic level, and that the v' 3 level is fed chiefly by molecules from the $v''=1$ level, according to the Franck-Condon principle. It may be pointed out, however, that the number of molecules in the $v''=1$ state, calculated from the Boltzmann law at a temperature of 470° A. (found from intensity measurements on the rotation lines of BO), is 1/370 that of the number in the v'' 0 state. It is therefore difficult to imagine that the $v''=1$ level plays any important part in determining the distribution in the upper electronic state. Further, the assumption that the Franck-Condon principle applies to transitions caused by active nitrogen is open to question. A. ELLIOTT.

The Red Coronal Line in Oxygen.

IN looking over my spectrum plates of oxygen I find some which show not only the nebular lines λ6300 and λ6364,[1] which had not been produced in the laboratory before, but also a strong line λ6374·29. The wave-length of this line seems to be identical with that of the strong, red coronal line λ6374·2.[2] Although this oxygen line is well known, I do not think that the above remarkable coincidence has been previously pointed out. This coincidence in the wavelengths of the oxygen and the coronal line, and also the fact that the line occurs in an isolated position in the oxygen spectrum when only lines of O I were present, would seem to indicate their identity, and is strong evidence of the presence of oxygen in the sun's corona.

This oxygen coronal line is still unclassified and its Zeeman pattern has not been observed. Possibly it represents a forbidden transition between terms still unknown. Such a study would be very interesting in throwing light on the spectroscopic nature of its end-terms and in helping to explain the nature of the solar corona. JOHN J. HOPFIELD.

The Compound SnSb.

DURING an investigation of the crystal structure o[f] the Sn-Sb alloys, the compound SnSb has been found to give an excellent X-ray powder photograph of the well known pattern common to sodium chloride structures. The atomic numbers of tin and antimony are 50 and 5[1] respectively, and as in potassium chloride having atomic numbers 19 and 17 respectively—odd order reflections from the 111 planes are absent. The results obtained from measurements on the film are given in the accompanying table. Observed and calculated values of the plane spacings are in very good agreement. The observed intensities of the lines on the film are also in agreement with calculated intensities.

Structure: NaCl Type.
Dimensions of Unit Cell: $a_0 = 6·092$ A.

The density of the compound is 6·94 gm./c.c.

giving four molecules of SnSb per unit cell as required by a sodium chloride lattice.

The arrangement of atoms into a sodium chloride type lattice would indicate that the compound is ionic in character. This requires the tin to be trivalent. From formulæ given by Pauling (*J. Amer. Chem. Soc.*, **49**, p. 765; 1927) the calculated ionic radii for Sn^{+3} and Sb^{-3} are respectively 0·75 and 2·45 A., which when built up into a sodium chloride structure, gives a lattice constant 6·40 A., in poor agreement with the observed value. However, the atomic radii for tin and antimony for co-ordination number 8 are 1·53 and 1·56 respectively (Goldschmidt; *Trans. Faraday Soc.*, **25**, p. 253; 1929), and for co-ordination number 6, these are reduced to 1·484 and 1·513 A. Such radii would give a lattice constant of 5·99, in good agreement with the experimental value 6·092 A.

The structure of SnSb is found to persist over the range 46 to 60 per cent tin with some change of lattice constant, showing that both tin and antimony are soluble in it. This agrees with the equilibrium diagram given by Broniewski and Sliwowski (*Comptes rendus*, **186**, p. 1615; 1928), although they thought a compound Sn_3Sb_2 existed at the end of this range—at 60 per cent tin. Our X-ray analysis, however, shows that the compound is definitely SnSb with a range of solid solution on either side. The solution of tin and antimony by the compound can be readily understood, since both metals have acidic and basic properties. In addition, their atomic numbers and atomic dimensions are practically the same, so that one atom of tin could be replaced by one of antimony, and vice versa. The solution of antimony up to 4 per cent causes a change of lattice constant from 6·092 to 6·106 A. Before annealing, the solution of 10 per cent tin causes a definite expansion to 6·124 A., but after annealing there is no measurable change.

A microphotograph due to Dr. J. E. Stead (*J. Inst. Metals*, **22**, p. 127; 1919) shows excellent cubic crystals of SnSb. Many of them were observed to be perfect cubes, having angles of 90° at each corner. The crystals have also been observed as the hard constituent of tin base bearing metals.

A full account of the investigation of the crystal structures of the complete system is to appear elsewhere.

Cause of High Winds of Oct. 19-20, 1917.

THE remark on p. 633 of NATURE of Oct. 18 (Historic Natural Events. Oct. 19, 1920) that, "Owing to the unexpected development of a barometric depression . . . a very strong cold north-east wind sprang up at some height above the ground", does not state the facts correctly and gives a misleading impression of the cause of the high winds at an altitude of 10,000-20,000 ft. on the occasion in question.

The winds at those heights over south-east England and northern France on Oct. 19-20, 1917, were northerly and not north-easterly. These winds occurred over a region where the horizontal gradient of pressure was insignificant at sea-level. This insignificant gradient, however, became a steep west to east gradient at great heights owing to the fact that there was a steep horizontal gradient of temperature in the upper air also from west to east. The strong northerly wind was simply a thermal wind. Generally, the actual wind is compounded of the thermal wind and the wind arising from the horizontal gradient of pressure at sea-level. On this occasion, as the latter was practically nil, the actual wind was practically coincident with the thermal wind.

A reasonably complete account of the conditions at the time is given in Vol. 4 of Shaw's "Manual of Meteorology", p. 112, along with the explanation of the phenomenon. I find on looking up my records that I gave the facts and the explanation to the General Staff at G.H.Q., France, on Oct. 23, 1917.

E. GOLD.

8 Hurst Close, London, N.W.11,
Oct. 24.

COL. GOLD is no doubt fundamentally correct as to the cause of the high winds of Oct. 19-20, 1917. My version agrees with that in McAdie's book, "Man and Weather", p. 12, which runs: "But a depression developed in the Atlantic, west of the British Isles, and the light variable winds, characteristic of settled fair weather, were routed quickly by cold north or north-east winds of 20 metres or more per second. The airships from midnight until 7 A.M. were carried south and somewhat east, at a speed of fifty miles an hour." A closer examination of the facts, however, shows that this view of the mechanism is too superficial. THE WRITER OF THE NOTE.

Scientific Inexactitude.

IN NATURE of Nov. 8, p. 725, Mr. Darling criticises a certain sentence in a recent book on "Sound". The sentence in question, "A clamped steel bar electrically maintained is sometimes employed as a rough standard of frequency", is described as 'unfortunate' and 'incorrect', and is given as an example of a tendency towards scientific slang.

Mr. Darling is, in effect, suggesting that all statements must be *explicit* in every detail, nothing must be implied. The sentence to which he refers is taken from a section entitled "Transverse vibrations of elastic bars" and from a sub-section commencing (24 lines away) "Electromagnetic methods of maintenance of the vibrations". One might reasonably expect, therefore, that even "a reader not conversant with the subject" would understand that the words "in vibration" are implied after the word "maintained" in the sentence quoted. I consider his alternatives "operated" or "driven" no better than the word actually used.

If all statements were explicit and nothing implied, a scientific book, or any other class of book, would make very dull reading. Mr. Darling's method applied to such well-known expressions as 'an oscillating circuit', 'a reversing switch', 'a projector screen', and so on, would lead to extremely laboured and amusing English. Abbreviation is essential to progress, provided that it is not carried beyond the intellectual limits of the reader, and I consider that the abbreviation in the sentence Mr. Darling quotes is entirely justified.

Applying his views to the opening sentence of his letter, what does Mr. Darling mean exactly when he says "a reader . . . may be completely fogged"? Presumably he does not really mean the *reader* is fogged any more than the sentence quoted means that the *tuning fork* is maintained? Again, what is an "unfortunate sentence"? The English language is based on such 'slang'.

A. B. WOOD.

The Lochaber Hydro-Electric Power Undertaking.

By Dr. Brysson Cunningham.

The remarkable engineering enterprise known as the Lochaber Hydro-Electric Power Undertaking, the first and main portion of which was brought to a successful completion early in the present year, embodies a number of novel and interesting features which justify a more extended notice than could be given in the brief paragraph in Nature of Aug. 9, p. 213, describing the visit of H.R.H. the Duke of York to the works of the Lochaber Water Power Company. The scheme, which is one of the most remarkable of its kind and certainly unique in importance in Great Britain, was promoted by the British Aluminium Co., Ltd., under the direction of Mr. Murray Morrison, director and general manager, who, with the late Mr. C. S. Meik, realised the latent possibilities of water power contained in Loch Treig and Loch Laggan, and devised a plan for their exploitation for the production of aluminium in a factory at Fort William. The work has been executed to the designs and under the supervision of Messrs. Meik and Halcrow, civil engineers, of Westminster.

Lochs Laggan and Treig are two natural storage basins in the Lochaber district of Inverness-shire, with surface levels some 800 feet above the sea. The former is about seven miles in length, with widths varying from a quarter to five-eighths of a mile; the latter, located seven miles or so from Loch Laggan, has a length of five miles and a width of five-eighths of a mile in its widest part. Both lochs have considerable depths, of the order of three to four hundred feet. The catchment area of the district covers slightly more than three hundred square miles. The average annual rainfall reaches a maximum of 160 in. at the top of Ben Nevis and falls to about 40 in. at Laggan Bridge. The minimum and maximum recorded on the summit of Ben Nevis are 108 in. and 240 in. respectively. In records covering a period of nineteen years, the wettest month produced 48·3 in. and the wettest day 7·3 in.

So far, operations have been confined to the development of that part of the scheme which affects Loch Treig, and they have comprised the driving of a tunnel from the loch to a point just above Fort William, where the aluminium factory is situated, together with the building and equipment of a power house. The tunnel was a remarkable project. It has a length of almost exactly 15 miles, appreciably larger than the Simplon ($12\frac{1}{4}$ miles) or, in fact, any European railway tunnel. In length, it is only exceeded by the Shandaken tunnel for the water supply of New York, which is just over 18 miles long, but this has a smaller cross-section, measuring $10\frac{1}{4}$ ft. by $11\frac{1}{4}$ ft. The transverse section of the Lochaber tunnel, though composed of several different segments, may be described as roughly circular with a diameter of 15 ft., the height being 4 in. less than the width. The interior lining is of concrete, faced with carefully smoothed cement, in order to reduce skin friction to a minimum.

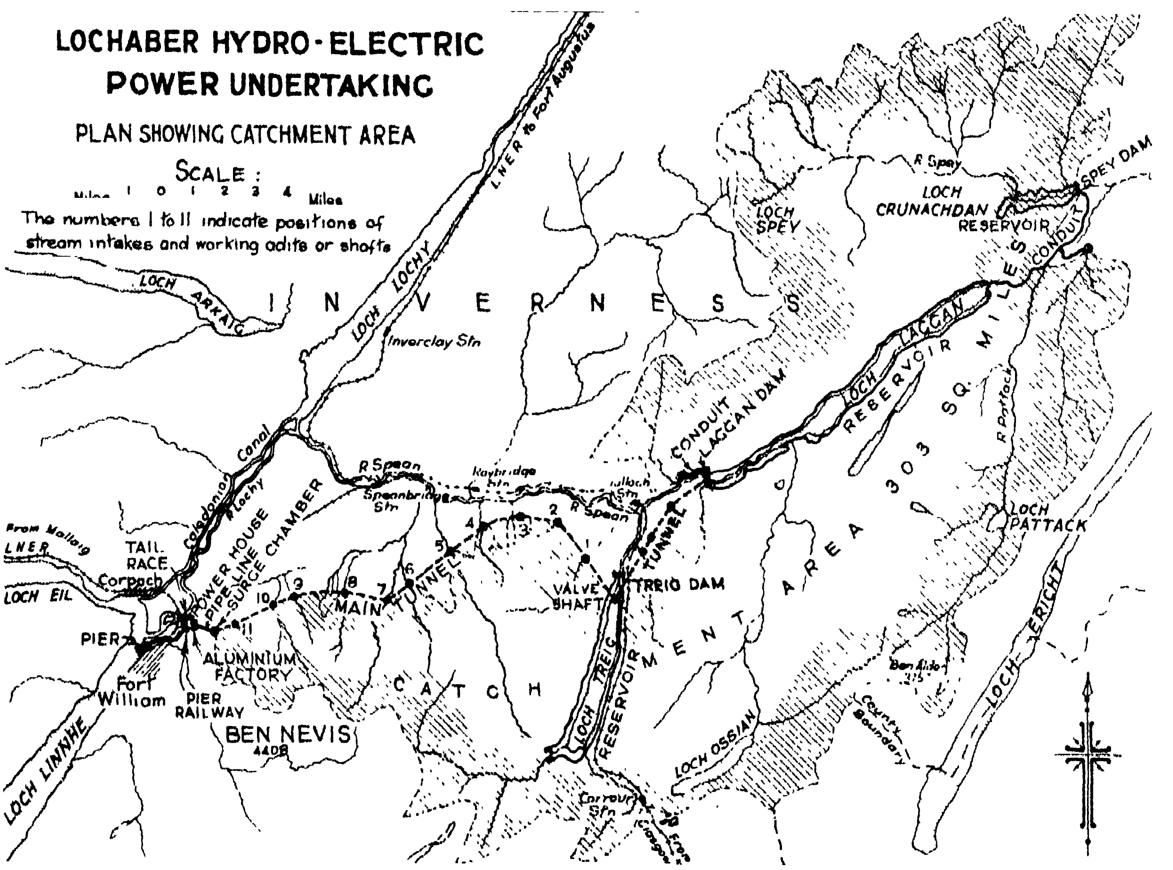

Fig. 1.

The strata along the route of the tunnel varied in character from grey granite of a very hard and compact nature at the Fort William end to schists (mica schist at Loch Treig) and porphyry with intervening layers of red granite, flagstone, etc. Such diverse material rendered drilling operations difficult and arduous, but happily there were no troublesome complications due to the presence of excessive water. Commenced in the summer of 1926, the bore was opened from end to end in February 1929. Driving was done from twenty-two faces: in addition to the end headings, there were seven horizontal adits from the mountain-side and three vertical shafts. The total length of the adits, which ranged individually from 400 ft. to 1440 ft., was 6360 ft.; and the aggregate depth of the shafts, which ranged from 145 ft. to 356 ft., was 1030 ft.

The tunnel undergoes two successive enlargements in its course for the purpose of receiving, as influents, eleven mountain streams, which are in this way incorporated in the main flow. The streams, or winter torrents, have been intercepted by dams and diverted into artificial conduits, rectangular in section with rounded corners. The water is abstracted over the crest of a weir in each dam, so as to cut off the passage of stones and heavy debris, while the weirs themselves are protected by grids, in order to intercept floating objects, tree branches, etc. The dams are also equipped with valve-controlled flushing pipes for dealing with silt accumulations, and spillways for the surplus flow in times of flood. The shafts by which the water is delivered into the tunnel are lined with concrete and are divided by a partition wall, extending from top to bottom, into two tubes, one of which is the water passageway, and the other, with a vent carried well above the top of the water tube, is a means of escape for the air sucked in by the water.

The pipe lines, 3200 ft. long, leading from the tunnel to the power house at the Fort William end, are to be three in number. For the present, however, only two are in service, the third line being blanked off. The two lines installed are formed of steel plating, from $\frac{1}{2}$ in. to $1\frac{1}{8}$ in. thick, and they vary in diameter from $70\frac{1}{2}$ in. to 65 in. They are in 30 ft. lengths, with lap-welded joints.

The power house on the left bank of the River Lochy is 270 ft. long by 65 ft. wide. Its position, half a mile from the river, has necessitated an exceptionally long tail race of a thousand yards, but the arrangement is justified by the corresponding saving in pipe line. For the present, less than half the generating plant contemplated for the full working of the undertaking is installed. There are five main turbo-generator units, of 10,000 horse-power capacity apiece. Each unit comprises a turbine of the Pelton wheel type, driving two generators on the same bedplate. The generators are direct current machines operating at 300 volts and 250 revs. per min. In addition, there are two subsidiary turbo-generators, each of 1250 kw. capacity, with alternators, triphase, 50 period, 400/440 volts at 600 revs. per min. The gross head available as yet is 764 ft., but when the surface of Loch Treig is raised as intended, the gross head will be increased to 800 ft.

As previously mentioned, the exploitation of Loch Treig is only a part (although as regards constructional difficulties the main part) of the whole scheme, which in its entirety envisages the inclusion of Loch Laggan in the supply service, and moreover proposes by the aid of artificial works to amplify and extend the resources of the whole catchment area. The minimum level of Loch Laggan in times of scanty rainfall is 818 ft. above Ordnance Datum, and by dredging the outlet it will be possible to draw it down to 804 ft. In times of heavy rainfall, however, the surface level rises to 820 ft. above O.D., and it is proposed to maintain it normally at that level by the construction of a dam, not actually at the extremity of the lake, but some distance down the River Spean, which drains the loch into the River Lochy, and so, in turn, into Loch Linnhe and the sea. The dam, which will be 700 ft. long and 130 ft. high, will, therefore, form an additional reservoir, to be known as the Spean Reservoir, which, linked up with Loch Laggan, will afford a combined area of 2440 acres and enable a depth of 16 ft. to be utilised for power purposes.

The surface level of Loch Treig is also to be raised from its present normal level of 783 ft. to 819 ft. above O.D., that is, 1 ft. below the impounded level of Loch Laggan and the Spean Reservoir, with which it will be connected by means of a tunnel 16 ft. in diameter. The tunnel will have a length of nearly three miles and a fall of 41 ft., so that the full available supply from Loch Laggan and the Spean Reservoir will flow into Loch Treig and the whole system be unified.

There are other sources which it is intended to utilise in succeeding stages, including the River Spey and its tributary, the Mashie. By building a weir across the former, its level will be raised during flood time by about 30 ft., resulting in the formation of a reservoir nearly two miles long, attaining a width of just under half a mile at its widest part. The crest level of the weir will be 880 feet above O.D., and in times of flood the excess over the normal flow of the river will be conducted through a conduit, nearly three miles in length, to the River Pattack, one of the influents of Loch Treig. An interesting point about the arrangement is that while the River Spey flows eastward and discharges into the North Sea, by the formation of this reservoir and conduit some of its water will be diverted westward, via Loch Treig, into the Atlantic.

This does not by any means exhaust all the potential sources of supply. There are several other streams the waters of which will be controlled and directed into the general storage reservoir of Loch Treig, which, by reason of its minimum net head of 695 ft., enables one horse-power to be realised for every five gallons of water per minute falling therefrom into the power house at Fort William.

Such in brief outline is the present position and the programme of future development. The completion, in due course, of the undertaking will crown an enterprise which, even in its present stage, is a unique and outstanding achievement in the annals of British water power development.

The Tercentenary of Cinchona in Medicine.

IN the dispensary of the Hospital de Santo Spirito in Rome, there is preserved a quaint fresco which bears the inscription :

Aegrotat Limae coniux Chinconia febrim
Cortice mirando pocula tincta fugant.

It depicts the Countess of Chinchon receiving from the hands of an Indian warrior the rare and wondrous bark which cured her of her fever. Probably the South American Indians knew the virtues of this bark long before the advent of the Spaniards, but apparently they attached little importance to it. Their story is that a native drank from a pool of water into which a cinchona tree had fallen and so was cured of his fever.

In 1630 Juan Lopez Canizares, Spanish *corregidor* of Loja in Ecuador, proved the efficacy of the bark of the fever tree (*Palo de Calenturas*). He is said to have recommended it to the Countess, and his is the first known instance of the use of quinine or cinchona bark in medicine. Quinine has now come to be highly valued and used throughout the world as indispensable for the cure and combat of malarial fever. So the tercentenary of the first use of quinine in medicine is this year being celebrated in Britain, America, and elsewhere, and it is appropriate to recall the outstanding incidents in the history of its utilisation and production.

The Countess of Chinchon, wife of the Viceroy of Peru, returned to Spain from Lima in the year 1640. She brought with her a supply of the precious bark and, soon thereafter, the valuable properties of 'Countess's Powder' became widely known in Europe. Nine years later, and for the ensuing twenty years, considerable quantities of the bark were sent from Peru to Spain by Jesuit fathers. Their brethren at home were responsible for its distribution throughout their own and neighbouring countries, and thus the powdered bark came to bear the name of 'Jesuits' Powder'. There is evidence to show that by the end of the seventeenth century the use of the bark had spread to France, Italy, and Holland. In England, Robert Talbor used the drug with great effect, and King Charles II., whom he had rid of a quartan fever, honoured him with knighthood.

We owe our first definite knowledge regarding quinine-yielding species and their geographical distribution to various French and Spanish scientific expeditions which visited South America between 1735 and 1852.

Linnaeus in 1742 named the genus *Cinchona* in memory of the great service to humanity rendered by the Countess of Chinchon. Misinformed as to her name, he spelt the word *Cinchona*, and unfortunately died before the error was pointed out by the Spanish botanists Ruiz and Pavon.

There are sixty-five species in the genus, but only three are worth consideration from the medical point of view, and these are *Cinchona officinalis*, *C. succirubra*, and *C. Ledgeriana*. The genus is indigenous only in South America and the various species are found scattered through primeval forests in Colombia, Ecuador, Peru, and Bolivia. They are to be found on the slopes of the Andes, in roadless and uninhabited regions at elevations between 2500 ft. and 9000 ft. on the eastern side of the main range. The Loja region in Ecuador is the home of *C. officinalis* and other 'crown barks', so called because they were reserved for the use of the royal pharmacy at Madrid. *C. succirubra*, the red bark, is found on the western slopes of Mt. Chimborazo, while the seed of *C. Ledgeriana* was obtained from Coroico province in Bolivia.

For many years the collection of bark in the forests was uncontrolled. Ruthless methods of exploitation by which the trees were killed long before they had yielded their full quota of bark made supplies more and more difficult to obtain. By 1847 no good bark was available within a ten days' march of inhabited country. Protests were raised and measures for protection and planting were suggested, but no safeguarding legislation was enforced. Meanwhile, the demand for the bark in Europe had greatly increased, and scientific men in various countries, perturbed by the difficulties of obtaining supplies and the extravagant methods of collection, began to urge their governments to introduce cinchona to their own colonies. Dr. Royle, curator of the Botanic Garden at Saharunpur, recommended that cinchona should be planted in India, and the Dutch botanist, Dr. Blume, made a similar proposal with regard to Java.

The distinguished French botanist, Dr. Weddell, whose monograph, "Histoire naturelle des Quinquinas", is one of the most important contributions to the literature on this subject, made two expeditions to Bolivia, in 1847 and 1852. He brought seed of *C. Calisaya* to Europe, from which plants were raised both in the Jardin des Plantes in Paris and in the Royal Horticultural Society Garden in London. Some of these plants eventually reached both India and Java.

For the extensive plantations contemplated, further supplies of plants and seed were necessary, and in 1851 Justus Karl Hasskarl, then superintendent of the Botanic Gardens at Buitenzorg, sailed for Peru. After many adventures he succeeded in reaching Java in 1854 with a number of plants of a species which, unfortunately, turned out to be of very little value and was given the name *C. Pahudiana*.

Sir Clements Markham with his fellow labourers, Dr. Spruce, Mr. Weir, Mr. Cross, Mr. Pritchett, and Mr. Ledger, were successful in introducing cinchona into India, in various consignments of plants and seeds, sent between the years 1861 and 1878.

Markham and Weir set out for the Caravaya forests in the spring of 1860 and reached the valley of the Tambopata River in May. On their return journey they met with considerable opposition, for the local government, fearing the ruination of their monopoly in the supply of bark, did their utmost to prevent the export of cinchona plants.

By following a devious route the explorers arrived at the port of Islay on the coast of Peru in June with a supply of plants which were placed in Wardian cases and shipped to India via Panama and the Red Sea.

Spruce and Cross were successful in collecting seed and plants of *C. succirubra*, the red bark, from the slopes of Mt. Chimborazo, and these were shipped from Guayaquil in January 1861. Cross made several subsequent expeditions; he went to the Sierra de Cajamuma from Loja in the autumn of 1861, bringing back seeds of *C. officinalis*; twice he visited the forests of Pitayo in the extreme south of Colombia to gather seed of *C. pitayensis*; and finally, in 1877, he travelled to the upper reaches of the Caqueta River to obtain the seed of *C. Calisaya* and the soft Colombian barks. Pritchett collected plants and seed of the grey barks, *C. nitida*, *C. micrantha*, and *C. peruviana*, from the Huanuco forests to the north of Lima.

Charles Ledger was engaged on his own account in the bark and alpaca wool trades in Peru. He had made several expeditions to obtain bark, in one of which his partner, Mr. Backhouse, was murdered by the Chuncho Indians and Ledger had only escaped with his life. Knowing the desire of the British and Dutch Governments to obtain seeds of the best species, Ledger sent his old Indian servant Manuel Mamani to the cinchona forests in the region of Coroico. Mamani, faithful to his trust, persevered and at length, after several years of search, delivered seeds from the best (the *roja*) trees to his master. But he had roused the enmity of the Bolivians and soon afterwards was thrown into prison, beaten and half starved. Robbed of all he possessed, he died of the ill-treatment he received. Manuel Mamani deserves be remembered, for to him we owe the seed of *Ledgeriana*. It is this species which in cultivation yields the highest percentage both of quinine and of the other alkaloids, and the productiveness of the plantations both in India and in Java is due mainly to the richness of its bark.

In the introduction of cinchona to India, the Royal Botanic Gardens, Kew, played an important part, not only by raising plants from seed, but also by tending those which arrived from Panama so that they might recuperate ere they faced the perils of their further journey through the Red Sea. Although there were many casualties among the plants which were dispatched from South America, some eventually arrived safely in India. From small beginnings made in 1861 the large plantations in the Nilgiris and in the Darjeeling district of Bengal were gradually established. To Mr. McIvor, of the Government Gardens in Ootacamund, and to Dr. Anderson, of the Royal Botanic Gardens, Calcutta, the task of developing the plantations was entrusted, and Dr. Anderson was succeeded by Mr. C. B. Clarke, Sir George King, and Sir David Prain. We owe to them, too, a debt of gratitude. They have built up a great enterprise. In India we have now under cinchona some 3500 acres, yielding about 40,000 lb. of quinine each year. India, however, is the only country within the Empire in which cinchona is seriously cultivated.

Much has been accomplished, but there is still much to be done. The potential demand for quinine is far in excess of available supplies. India provides only about one third of the amount of quinine she herself at present consumes. It has been estimated that in order to have any effect upon her malarial problem, she would have to increase her production by eighteen times; and what of the needs of the rest of the Empire and the 800,000,000 people who suffer from malarial fever?

There can be no more fitting manner in which to mark the tercentenary of the first use of quinine than by reviving and renewing our efforts to increase the production of cinchona, the principal agent in the combat of malaria. The problems to be faced are the finding of further areas of suitable land and the application of scientific research to increase the output from existing plantations. May we look forward hopefully to the time when the united efforts of the administrator, the medical officer, the planter, the manufacturer, and of those responsible for distribution and propaganda have brought the scourge of malaria well under control—when Sirius no longer

"O'er the feebler stars exerts his rays;
Terrific glory! for his burning breath
Taints the red air with fevers, plagues, and death."

Obituary.

COL. J. W. GIFFORD.

COL JAMES WILLIAM GIFFORD, whose death occurred at his home at Chard, Somerset, on Oct. 27, in his seventy-fourth year, was one of that select band of scientific workers of whom Sir William Spottiswoode, Warren De La Rue, and others were brilliant examples; men who, in addition to their ordinary occupations, found time and opportunity to follow the pursuit of pure science for the love of it. Col. Gifford was by profession a lace manufacturer, and at his death was managing director of the firm of Messrs. Gifford and Fox, of Chard.

The present writer was first brought into touch with Col. Gifford in connexion with an inquiry into the so-called musical properties of some sands that are found on the coasts of Scotland and elsewhere; these sands, when trodden upon, emit a musical note or squeak which becomes fainter and is soon lost altogether if the same specimen is used repeatedly. Col. Gifford found, by the simple operation of rolling the sand down an inclined board several times, that the musical property was restored evidently by the removal of the fine dust of silica that was produced by the rubbing together of the grains of quartz.

On the discovery of X-rays by Prof. Rontgen in 1895, Col. Gifford entered with enthusiasm upon the new field of research and became an active member of the Röntgen Society, which was founded

by the late Prof. Silvanus P. Thompson, and he soon became an authority on the subject. He gave his services to the members of the medical profession at Chard and made many radiographs for them in the early days of the science.

Col. Gifford's chief activity was, however, in the field of optics, and he was the author of many valuable papers dealing with the construction and improvement of telescopic lenses. He was an active fellow of the Royal Astronomical Society, the Optical, Microscopical, and other kindred Societies, and communicated several important papers to the Royal Society, in the *Proceedings* of which the following are published: "The Refractive Indices of Fluorite, Quartz, and Calcite", "The Refractive Indices of Water and Sea Water", "The Refractive Indices of Benzene and Cyclohexane", and "The Existing Limits of Uniformity in producing Optical Glass".

Col. Gifford was the author of a book on "Lens Computing by Trigonometrical Trace". In a foreword to the book, Prof. F. Cheshire, formerly director of the Technical Optics Department of the Imperial College of Science and Technology, pointed out that "Col. Gifford never relied upon the glass-makers' catalogue for the optical constants of the glasses, but determined these data for himself, and the excellency of the systems that he produced was undoubtedly due to this fact". In the old Volunteer Force he held the position of hon. colonel of the Fifth Somersets, and when the War broke out he took an active part in military matters. He was sent to the front by the War Office to report upon the proposed introduction of giant periscopes for use in the trenches, and later on produced a convenient short high-power telescope for the use of officers.

Taking an active part in local affairs in Chard, Col. Gifford was chairman of the Board of Governors at Chard School, of which he was an old boy; and for many years he maintained at his own expense a nurse for the district. He will be greatly missed there by all who knew him. In 1883 he married Emma, daughter of Mr. Ernest Rossiter, of Taunton, to whose assistance in his scientific work he pays grateful tribute in many of his papers. He had one son and four daughters, all of whom survive him.

J. H. GARDINER.

WE regret to announce the following deaths:

Dr. J. W. Evans, C.B.E., F.R.S., a past president of the Geological Society and of Section C (Geology) of the British Association, on Nov. 16, aged seventy-three years.

Dr. E. R. Frazer, a distinguished pathologist and benefactor of the University of Oxford, on Nov. 17, aged sixty-three years.

Dr. G. H. K. Macalister, formerly principal of the Singapore Medical College and editor of the *Malaya Medical Journal* on Nov. 2, aged fifty one years.

Dame Mary Scharlieb, D.B.E., a pioneer in medical education for women, on Nov. 21, aged eighty-five years.

Prof. J. H. Teacher, St. Mungo (Notman) professor of pathology at Glasgow University, on Nov. 21, aged sixty-one years.

News and Views.

DISSATISFACTION with the Government's decision to allow the Dyestuffs (Import Regulation) Act to expire on Jan. 15 next is not confined to circles associated with an industry of exceptional national importance; it is shared by all those who have a care for chemical education and research in Great Britain. The intimate relation which connects the existence of a flourishing dyestuffs industry on one hand with the acquisition and application of knowledge in many other branches of organic chemical science and on the other hand with the supply and facilities for training of competent organic chemists has already been pointed out in the columns of NATURE. This relation is patent to members of the scientific community, and it should not be difficult of appreciation by those responsible for the oversight of our economic and educational destinies. It is not our desire to enter into the polemics of the political aspect of the matter, although it would indeed appear from reports of Mr. Graham's answers and Sir P. Cunliffe-Lister's question in the House of Commons on Nov. 19 that prejudice to the dye-user could easily be avoided. The substance of our protest is rather that, so far as the evidence at present available appears to indicate, the decision rests entirely on political opinions and ignores facts which relate both to the progress of science and to the maintenance of British scientific standing. Until scientific education is more widespread than at present, it would be unreasonable to expect our political leaders themselves always to exercise appropriate judgment in scientific matters, but they are not thereby absolved from the duty of basing their actions on questions of fact ascertained judicially or otherwise.

ORIGINATING with Sir William Perkin's classic researches, the coal-tar dyestuff industry in Great Britain was an early victim to German scientific enterprise and organisation. A tardy realisation of the place of chemical science in the national economy born of war conditions, followed by effective political action during the past ten years, has resulted in the home production of dyes rising to so much as 93 per cent of the consumption; coincidently there have grown up in the universities of Great Britain and in industrial laboratories active schools of research directed towards a strengthening of the foundations of the chemical industries in general. This fundamental work has been in large measure rendered possible by direct assistance and by offers of employment by the industries concerned. Even were it possible to ignore the incidence of these developments on intellectual momentum, on future employment in parallel branches of manufacture, and on health and comfort, there still remains the fact that a million pounds is spent annually in the purchase of foreign

dyes. Deprived of effective protection and encouragement, and exposed to the full blast of world competition in home markets, the industry may survive, but it can scarcely be expected to develop in the way which our national security demands. It is earnestly to be hoped that the decision which has been announced is amenable to modification on reconsideration, and that in the event of its being confirmed, alternative means to encourage progress in organic chemical industry and education will be immediately substituted.

AT the anniversary meeting of the Royal Society one hundred years ago, a new president had to be elected as a successor to Mr. Davies Gilbert, who had resigned office. Other changes were also necessary at the time, choice having to be made, respectively, of a new treasurer, secretary, and foreign secretary. The considerations attending an appointment to the presidential chair were, in many aspects, peculiar, yet apparent. At the period in question dissensions and breaches were rife in the scientific hierarchy, due, it may be, partly to transmitted differences, partly to lack of adaptability to current movements in science. The relevant history of this perplexing era remains, however, to be written. Two candidates for election were put forward: (1) no less a personage than H.R.H. Augustus Frederick, Duke of Sussex, and (2) J. F. W. Herschel, the distinguished astronomer and physicist, designated in influential circles as eminently qualified by his varied and profound knowledge, and as one acceptable to men of science in England and in foreign countries. Weld, the compiler, records that the selection of a president was left in the hands of the general body of fellows coming to the anniversary meeting. The public journals announced that in the ballot the Duke received 119 votes, Herschel, 111. It is of interest to note here that Herschel had been elected into the fellowship in 1813 and when twenty-one years of age; also, that Faraday was a member of council in 1830.

IT was resolved that a deputation should wait upon the newly elected president and inform him of the decision taken. Further, it is recorded (in the same public manner) that His Royal Highness had afterwards addressed the fellows, assuring them that he would use every endeavour to advance the interests of science and of the Society. He stated that it was his intention to throw open his house alternately on the forenoons and evenings of Wednesdays for the reception of the fellows and men of science; those who could not do him the pleasure of breakfasting with him, might be able to attend from half-past eight to eleven at night. The Duke maintained the duties of office until Nov. 30, 1838, and we are told that during his tenure of the presidency he constantly presided at all meetings of the council and Society. It was to Davies Gilbert, the president referred to above, that the eccentric Earl of Bridgewater, who died in 1829, left by will the sum of £8000, placing upon him the responsibility of nominating some person or persons to write, print, publish, and expose to public sale one thousand copies of a work "On the Power, Wisdom, and Goodness of God, as manifested in the Creation". The 'Bridgewater Treatises' were published in 1833–35, Whewell, Charles Bell, Buckland, and others providing the essays.

IN the year 1830 the Royal Society did not allot its Copley medal; neither, by the way, had it done so in the two previous years. Also, the gift of the Rumford medal was intermitted in 1830. Medals were given only to David Brewster and Prof. Antoine Jérôme Balard, of Montpellier, who each received a Royal medal, the former "for his communications to the Royal Society on the Polarization and other properties of Light"; the latter "for his discovery of Brome". Brewster was elected into the Royal Society in 1815; in the same year he was awarded the Copley medal, a double distinction probably in character without any parallel. Antoine J. Balard was born at Montpellier in 1802, and he died in Paris in 1876. Originally Balard had worked in his native town as a pharmacist, but, later on, researches in various branches of applied chemistry claimed his undivided interest. In 1826 he succeeded in isolating from sea-water the chemical element bromine, whilst he studied its compounds in sea-water, particularly from the point of view of production for industrial purposes. A wider sphere offered itself in Paris as successor to Thenard at the Faculté des Sciences; in addition, in 1851, he was appointed professor of chemistry in the Collège de France. Balard was elected a member of the Paris Academy of Sciences in 1844, but his name does not appear on the foreign membership roll of the Royal Society.

THREE fellows of the Royal Society, all of them distinguished by long and notable scientific activity, have celebrated birthdays during the past week. They are, respectively: Prof. J. Cossar Ewart, a graduate and formerly Regius professor of natural history of the University of Edinburgh, who, on Nov. 26, entered on his eightieth year; Prof. Horace Lamb, a graduate of Trinity College, Cambridge, and formerly professor of mathematics in the University of Manchester, who, on Nov. 27, reached the age of eighty-one; and Sir J. Crichton-Browne, also a graduate of Edinburgh, past president of the Medical Society of London, the Neurological Society, and the Medico-Psychological Association, and for many years treasurer of the Royal Institution, who attained the age of ninety on Nov. 28. To all three our hearty congratulations are extended.

"BIOLOGY in Education and Human Life" was the subject of the Henry Sidgwick Memorial Lecture for 1930, delivered at Cambridge by Prof. A. V. Hill. It was a strong plea for a wider appreciation of the interest and value of biology in human affairs. At present, biology is unfairly handicapped. At school, classics and sciences like mathematics, physics, and chemistry usurp the time-table to the exclusion of biology, biasing the outlook of youth before it can decide the course of its own likings, and forming an anchorage of knowledge which the student fears to leave on a voyage into the unknown. "As a practical

step biology must demand that, with all its intellectual interest and its importance in human affairs, it should be brought sufficiently to the notice of boys and girls to enable them to decide with their eyes open whether that, or something else, is what they wish to study." It is, indeed, a strange thing that a science fundamental to an understanding of the world around us and of the workings of the human body and mind should be regarded as a sort of cultural embellishment, when the reasonable position is that ignorance of the nature of living things should be looked upon as a real lack of education. The pity is the greater because children in general, regardless of their upbringing, find the world of living Nature vastly interesting, and so far from finding it beyond their grasp, they display ample evidence in their biological studies of ability to classify facts, recognise relations between ideas, make generalisations, and formulate results.

PROF. HILL proceeded to illustrate from current problems in human affairs the necessity of a sound biological point of view. The incidence of feeble-mindedness and the limited extent by which it may be reduced by the methods generally urged by eugenists, the impossibility of amalgamating social notions and race improvement based upon the type of selection and breeding common to the development of domestic animals, the fallacies of sense observation and mental processes—these and many other problems can be understood only when brought into relation with the known facts of biology. There is something to be said for the creation in the universities of professors of conjuring, so that proper emphasis may be placed upon the extreme fallibility of the senses. In the wider study of humanity, also, biology must play an important part. It offers the most humane and charitable approach to the study of human conduct: its exploration of mankind as a biological unit may become a field of extraordinary fertility and significance for the future of the race; and perhaps its most important service would be to give man a reasonable attitude towards life. The address should be read by all educationists, and not least carefully by the exponents of classics, mathematics, physics, and chemistry. Prof. Hill has kindly consented to its publication shortly as a Special Supplement to NATURE.

MR. ARNOLD BENNETT, in the course of an article in the *Evening Standard* of Nov. 20 on Sir James Jeans's book, "The Mysterious Universe", pays NATURE a compliment which we gratefully acknowledge. He says, "I regard NATURE as perhaps the most important weekly printed in English, far more important than any political weekly. My esteem for NATURE is enormous, for I have learnt a tremendous lot from it. But the writing of it is considerably inferior to the matter of it." As examples of this inferiority, Mr. Bennett quotes two sentences from an article in our issue of Nov. 8. We suggest to him, however, in all humility, that similar examples of careless construction could be selected from the pages of any issue of any literary periodical, and that his generalisation is scarcely just to us. We cannot pretend that the highly specialised subjects of modern science can always be described in words of common speech, but we do endeavour to maintain a high standard of English in contributions generally, and we regret as much as anyone when slipshod or ambiguous phrases escape our notice. It would be easy, however, to find on almost every page of every issue of the *Evening Standard* worse examples of hasty or clumsy writing than the two quoted by Mr. Bennett from a single article in NATURE; but no doubt he assumes that our literary standard should be higher than that of an evening newspaper—as indeed it is.

THE Association of Scientific Workers, in spite of the financial stringency with which it, like other good causes, is afflicted, still adds to its record of achievement. During the past few months it has prepared, and submitted to the Royal Commission on the Civil Service, a formidable body of evidence dealing with the position of the scientific Civil servant *vis-à-vis* his administrative colleague, and advocating the unification of all the State scientific services under a Ministry of Science. At the same time, the Association has prepared an index of references to science and cognate matters in the Parliamentary Debates, and through its general secretary, Major A. G. Church, M.P., has formed a Parliamentary Science Committee. This Committee, consisting of members of both Houses and all parties, meets periodically to hear the views of acknowledged experts on scientific questions which bear on public affairs.

SOME years ago the Association issued an appeal for members, in the form of a letter signed by some of the most prominent men of science in Great Britain. This letter was sent to about 20,000 scientific workers, and resulted in a large increase of membership. At the present time the Association is sending out another such appeal, on a much more elaborate scale. It consists of a sixteen-page booklet entitled "The Profession of Science", containing articles by Sir Richard Gregory, Prof. Julian Huxley, and others, with messages from Sir Ernest Rutherford, Sir William Bragg, the Rt. Hon. W. G. A. Ormsby-Gore, and Prof. Donnan, and a preface by Sir Daniel Hall as president of the Association. The booklet is being sent to 25,000 scientific workers, and at the same time a card index of qualified scientific men is being prepared, with the intention of preserving it and keeping it continually up-to-date. In this way, as a by-product of the Association's own propagandist activities, information is being collected which will prove invaluable when it becomes possible to create an authoritative register of the profession of science, such as the professions of law, medicine, dental surgery, and teaching already possess. Work on this card index has been in progress for four weeks, and it is already clear that the figure of 25,000 falls considerably short of the total of qualified workers in Great Britain.

AT the annual general meeting of the British School of Archæology in Jerusalem, which was held on Nov. 21, Prof. J. L. Myres, chairman of the Council, made the first public announcement of an important archæo-

logical enterprise which is to be undertaken on an international basis. Harvard University, which has been considering an intensive investigation of the important site of Samaria, excavated in part only by Dr. Reisner, has invited the co-operation of the Palestine Exploration Fund, the British School of Archæology in Jerusalem, and the Hebrew University of Jerusalem. The British Academy has also consented to co-operate and has promised a contribution of £1000 from the accumulated income of the Scheiwz Fund towards the expenses of the British wing in the first year. The work will be under the direction of Mr. J. W. Crowfoot, who will leave England shortly to make the preliminary survey and organise the labour required. It is expected that the actual work of excavation will begin in March or April next and continue until well into the summer as weather permits. An undertaking has been given to provide about £1000 a year for the next three years to meet the liberal proportion which Harvard and its friends are providing.

THE Electricity Commissioners have issued a 'return of the fuel consumption and units generated' in Great Britain for the year ended Mar. 31, 1930 (London: H.M. Stationery Office). The first return was issued for the year 1921 and the comparison of the results is very satisfactory. In 1921 there were 463 power stations and 3·32 lb. of coal and coke were used per kilowatt hour generated. Last year's return covers 568 power stations, the average consumption being 1·97 lb. per unit, or only a little greater than a half that of nine years ago. The most economical station was that at North Tees, which had a consumption of 1·28 lb. of fuel per electrical unit generated. At twelve very large power stations the consumption was less than 1·5 lb. per unit. In 1921 the most economical station consumed 1·7 lb. per unit. The total electricity generated last year increased ten per cent above that of the preceding year, while the total fuel consumed increased only six per cent. During the year 33 stations were closed, 13 new stations were put into operation, and returns for 24 more are given for the first time. The North Tees station of the Newcastle-upon-Tyne Electric Supply Company obtained an average thermal efficiency of 23 per cent taken over the whole year. These figures prove that the provisions of the Electricity (Supply) Act, 1926, are beginning to act beneficially for the country. Whilst water power stations only produced 1·38 per cent of the total, the utilisation of waste heat from blast furnaces, etc., produced 2·06 per cent of the total.

IN a previous issue (Aug. 9, p. 220) we gave a preliminary account of the recent descent in the Atlantic Ocean to a depth of 1426 feet by Dr. William Beebe and Mr. Otis Barton in the 'bathosphere'. An article by Mr. Barton in the October issue of the *Scientific American* gives further details of this remarkable apparatus. The bathosphere, which was designed by Mr. Otis Barton and Mr. J. H. J. Butler, is a single spherical steel casting 4 ft. 9 in. in diameter, with walls more than $1\frac{1}{2}$ in. thick, and weighing 5000 lb. Access is gained by a 400 lb. door which can be screwed down on a special gasket and packed with white lead to be waterproof under a test submersion to 2400 ft. There are three projecting windows, each of which will take a cylinder of fused quartz 8 inches in diameter and 3 inches thick. In the dive in question, only two of the quartz cylinders were in place, the third window having been closed with a steel plug temporarily owing to damage to the quartz in fitting. These windows withstood submersion to a depth of 2400 ft. The breathing apparatus was designed by Dr. Alvan Barach, of New York, and consisted of two oxygen tanks fitted with special valves. A valve was set to allow 2 quarts of oxygen to escape per minute for the two divers. Under these conditions, each tank would last about three hours. Soda lime and calcium chloride held in wire mesh trays were used to absorb the carbon dioxide and moisture respectively from the air. The divers were in the tank for more than an hour and a half and felt no untoward effects beyond a slight excess of pressure. The bathosphere was operated by a 5-ton winch holding 3500 feet of $\frac{7}{8}$ in. steel centre non-spinning cab capable of sustaining 29 tons.

THE Annual Report of the Director describes the activities of the Meteorological Office during the year ended Mar. 31, 1930, the seventy-fifth year of its existence and the tenth year since it has been a department of the Air Ministry. The year was one of great activity in international co-operation, and, as well as meetings of several commissions, the report includes accounts of three important conferences—the International Conference on Safety of Life at Sea, in London in April and May 1929; the Conference of Empire Meteorologists, in London in August; and the International Conference of Directors of Meteorological Services, at Copenhagen in September. These conferences led to the recognition of marine meteorology in international treatises, to a radical improvement in the interchange of meteorological data throughout the world, and a much closer connexion between the meteorological services of the British Empire. During the year a new international code for the transmission of the meteorological messages, approved at the Copenhagen Conference, was adopted. Among other matters in the Report it is of interest to note that at the Copenhagen Conference the proposals for a second Polar Year in 1932–33, fifty years after the first in 1882–83, was adopted with enthusiasm. The proposals now under discussion are that a number of small observing stations should be established around and within the Arctic regions, and similarly so far as possible in and around the Antarctic regions, where observation of terrestrial magnetism, aurora, weather, upper air currents, and temperature should be carried out during twelve months according to an international plan.

IN the issue of NATURE for Aug. 16 (p. 259) we published a brief résumé of certain observations by Dr. Harry L. Shapiro on the physical characters of the descendants of the mutineers of the *Bounty*, which had appeared in the *Memoirs of the Bernice P. Bishop*

Museum of Honolulu. The well-authenticated origin of these people and their prolonged isolation give them an especial importance in anthropological science. Studies of hybrids based upon well-attested data in which the component factors can be distinguished with any certainty have not often been made. Although we dealt with physical characters only, Dr. Shapiro went on to record further impressions which are of considerable psychological and sociological import. A correspondent has written to us stressing this aspect of Dr. Shapiro's work in relation to the discussion of the "so-called 'inherent defects' of 'half-castes'". The writer quotes the following passage in particular from Dr. Shapiro: "This study of race mixture on the whole rather definitely shows that the crossing of two fairly divergent groups leads to physical vigour and exuberance which equals if not surpasses either parent stock. . . . This conclusion regarding the physical vigour of the Norfolk hybrids applies also to their social structure, which on Pitcairn was not only superior to the society instituted by the Englishmen themselves but also contained elements of successful originality and adaptability". So far, then, as Dr. Shapiro's observation goes, neither cross-breeding nor in-breeding has produced any evidence of degeneration in these people, but it is obvious that certain reservations would have to be made before this conclusion could be given extended application It is to be noted, however, that the Pitcairn Islanders are an instance of hybridisation in which no allowance has to be made for the social factor of an adverse environment which so often vitiates argument concerning cross-breeds.

THE Report of the Scottish Marine Biological Station for the year ending Mar. 31, 1929, shows very satisfactory progress. Before their departure to the Great Barrier Reef, Miss M. Marshall and Mr. A. P. Orr continued in the spring their plankton investigations on the diatom increase in Loch Striven and the physical and chemical conditions accompanying it. This was much less regular than usual, owing mainly to the strong winds mixing the water down to a considerable depth and carrying the diatoms below, where photosynthesis was impossible. Cultures of diatoms were sunk at different depths at the same time and their photosynthesis measured by the oxygen production. The results showed that the depth limit of growth was much affected by the presence of diatoms in the water, the water becoming more and more turbid as the diatoms increased, the turbidity decreasing again as the diatoms sank. Experiments showed that an actively growing diatom culture adds no perceptible quantity of soluble organic matter to the culture fluid. Mr. J. Mitchell, working on the food of the copepod *Pseudocalanus elongatus*, concludes that it feeds mainly on diatoms, for although no skeletal remains were found inside the gut, a green fluid was present in half the specimens examined and a similar green fluid was in the guts of *Pseudocalanus* living in a persistent culture of the diatom *Coscinosira polychorda*. Mr. H. B. Moore and Mr. R. G. Neill have been analysing the Clyde mud from various stations and find significant difference between the muds of different levels. Miss Lloyd has investigated the marine bacteria of the Clyde area, and Mr. A. C. Stephen has continued his researches on the biology of *Tellina tenuis*.

THE Department of Geology of the British Museum (Natural History) has received a plaster cast of the skull of Peking man. The skull has been described in NATURE by Prof. G. Elliot Smith (Mar. 22, p. 448, and Aug. 9, p. 210.) Recent accessions in the Department of Entomology of the Museum include more than 1400 specimens of two-winged flies (Diptera) from Mt. Kinabalu (13,455 ft.), British North Borneo. Many plants and animals (including even birds) found there do not occur anywhere else in the world, and possibly represent old forms of life which have persisted on the mountain during successive ages. Some species show affinities with the mountain fauna of the Philippine Islands. Similar interest attaches to the presentation by Dr. K. H. Barnard of five species of the remarkable African stagbeetles of the genus *Colophon*, including the types of four species discovered by the donor and new to the collection. These insects are confined to mountain summits in the south-western area of the Cape Province, South Africa. They are unable to fly, and each form is completely isolated from the other species. Stagbeetles are woodfeeders, and the occurrence of representatives on treeless South African mountain-tops is at present unexplained. The Rev. J. W. Spreckley has presented to the Department of Botany three bundles of the Chinese fungus, *Cordyceps sinensis*. This fungus attacks the larva of an insect which eventually dies, and its interior is gradually absorbed until it is practically a solid mass of mycelium though it retains its shape. Out of one end the fertile part of the fungus grows. It is a celebrated drug and is found apparently only on the Tibetan border. It is said to bestow energy and to be partaken of with stewed duck. Another interesting gift is a quantity of hazel nuts of immediate post-glacial date, from Loch Treig, Inverness-shire, presented by the North British Aluminium Co., Ltd. This year, owing to an unusual spell of dry weather, the level of the lake was reduced and a thick bed of dark-coloured hazel nuts was seen at the north (exit) end of the lake at 741 ft. above sea-level.

DR. C. S. MYERS, who has been Director of the National Institute of Industrial Psychology since its inception nine years ago, has asked to be released from the duties of directorship, and has been appointed Principal in order that he may devote the whole of his time to the Institute's research and educational activities. Dr. G. H. Miles, who has been Assistant Director for several years, has now been appointed Director of the Institute and will take charge of the whole of its practical activities. The number of firms requesting advice from the Institute has been a record one this year, and the number of young people applying to the Institute for recommendations as to the careers to which they are best suited has increased by 50 per cent on last year.

AT a Congregation held at Oxford on Nov. 22 the degree of D.Sc. was conferred on Mr. J. J. Manley, research fellow of Magdalen College. Dr. Manley's work, extending over thirty-five years, includes papers concerned with the preparation of 100 per cent. nitric acid (with V. H. Veley, *Phil. Trans.*, 1898), devices for increasing accuracy in weighing (*Phil. Trans.*, 1910), the apparent change in mass during chemical reaction (*Phil. Trans.*, 1912), and the union of helium with mercury (NATURE, Dec. 13, 1924, p. 861; *Phil. Mag.*, 1927). His work upon the law of conservation of mass is a distinct advance upon that of Landolt, due to the greatly increased accuracy in weighing, and the simplicity of the reaction studied (barium chloride and sodium sulphate). Dr. Manley is now engaged upon a study of the change in physical properties (other than boiling point) of benzene and its homologues when submitted to prolonged drying.

AT a well attended meeting of medical men and women representative of the study and practice of physical methods of treatment, held on Nov. 14 under the chairmanship of Sir Leonard Hill, it was resolved to form a Society of Physical Medicine. A sub-committee under the chairmanship of Sir Leonard Hill was appointed for the purpose of drafting a constitution and dealing with other urgent matters. The acting honorary secretary is Dr King Brown, 69 Grove Park, Denmark Hill, London, S.E.5.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned: A lecturer in civil engineering at Armstrong College—The Registrar, Armstrong College, Newcastle-upon-Tyne (Dec. 8). Temporary assistants under the Department of Agriculture for Scotland for, respectively, work on virus diseases of the potato and for field work in connexion with potato culture—The Establishment Officer, Department of Agriculture for Scotland, Queen Street, Edinburgh (Dec. 9). A part-time physics demonstrator at the London (Royal Free Hospital) School of Medicine for Women—The Warden and Secretary, 8 Hunter Street, W.C.1 (Dec. 10). A professor of education in the Rhodes University College, South Africa—The Secretary, Office of the High Commissioner for the Union of South Africa, 73 Strand, W.C.2 (Dec. 15). A resident lecturer in fruit and vegetable preserving at the Swanley Horticultural College for Women, Swanley—The Secretary, Horticultural College, Swanley, Kent (Dec. 15). An assistant in botany in the University of Glasgow—The Professor of Botany, The University, Glasgow, W.2. A head of the Chemistry Department in the Chulalongkorn University, Bangkok, Siam—The Siamese Legation, S.W.7. A part-time physics demonstrator at King's College of Household and Social Science—The Secretary, King's College of Household and Social Science, Campden Hill Road, W.8.

Our Astronomical Column.

Comet 1930 g.—*Circ.* No. 304 of the I.A.U. Bureau, Copenhagen, announces the discovery of a comet of magnitude 13·5 by Prof. Nakamura at Kyoto, Japan, at $13^h\ 50\cdot0^m$ U.T. on Nov. 13, its position being R.A. $3^h\ 40^m\ 41\cdot5^s$, N. Decl. 18° 53′ 25″. The comet is 1930 *g*, being the seventh discovery this year, but the eighth to pass perihelion this year. The above circular wrongly assigns the letter *f* to it; that letter was assigned to Tempel's periodic comet.

Mr. Sibata has deduced the following parabolic elements for the new comet:

$$\begin{array}{lll} T & \text{1930 Aug. 21·370 U.T.} & \\ \omega & 40°\ 19' & \\ \Omega & 231\ \ 26 & \Big\} \ 1930\cdot0 \\ i & 8\ \ \ 7 & \\ \log q & 9\cdot3071 & \end{array}$$

The following ephemeris for 0 h. U.T. is calculated from these elements:

	R.A.	N. Decl.	log r.	log Δ
Nov. 28.	$3^h\ 6^m\ 10^s$	16° 14′	0·3353	0·0792
Dec. 2.	2 59 35	15 42	0·3477	0·1082
Dec. 6.	2 53 57	14 58	0·3595	0·1433

The comet is well placed for observation, being not far from opposition; the distance from both sun and earth is increasing, so it will fade fairly rapidly. The small inclination suggests that it may prove to be periodic.

Fireball.—Mr. Denning writes: "A brilliant fireball was observed by the Rev. F. H. Carr-Gregg of Nuneaton, on Nov. 16, at $9^h\ 44^m$ P.M. It moved slowly, being visible for 5 seconds, and gave a strong outburst of light before it disappeared. Its flight was from 165° + 55° to 135° + 35° and its probable radiant point was in the south-west region of Hercules or near the star alpha Capricorni. Another observation would be valuable for the purpose of computing its real path. It must have been a very lustrous object as seen from the north-western counties of England."

The Leonids.—A few Leonids appeared on Nov. 16–17, but they were less in number than the meteors which are usually seen during an ordinary display of the Perseids. They were, however, more active than in several preceding years, and gave promise that in 1931 and 1932 they may be observed in greatly increasing numbers.

Pluto.—An article by E. C. Bower and F. L. Whipple in *Publ. Astr. Soc. Pacific* for August 1930 states that the Mount Wilson plates of December 1919 were taken with the 10-inch refractor specially to search for the Lowell planet; this was, however, so much fainter than was expected that the images were not detected until last June, when a fairly accurate ephemeris was available derived from the positions of 1927 and 1930: they were then located with the aid of a blink microscope. The final orbit of Messrs. Bower and Whipple represents the observations as follows;

Date.		Place	Observed R.A.	Tabular Decl
1919	Dec.	Mt. Wilson	+0·8′	+2·8′
1921	Jan.	Yerkes	+13·6	3·4
1927	Jan.	Yerkes	+0·2	2·1
1927	Jan.	Uccle	+3·5	+2·2
1930	Jan.	Flagstaff	-2·3	2·9
1930	Feb	Flagstaff	.	-0·5
1930	Mar. 26	..	0·0	0·0
1930	April 24	..	+0·3	+0·1
1930	May 24	..	0·0	+0·2
1930	Aug 21	Yerkes	-0·5	-0·1
1930	Aug 22	Yerkes	-0·6	+0·6
1930	Sept. 1	Yerkes	+0·2	+0·2

The revised Uccle position of 1927 January has been used.

The nearest approach to Neptune in recent years was 19 units in 1892; that to Uranus was 30 units in 1853. The Gaussian constant in the investigation was taken as 0·017213628; this is derived by adding the masses of all the planets to that of the sun.

Research Items.

Hawaiian Feather Cape. A remarkable feather cape, practically in mint condition, is figured and described in *Man* for November, by the owner, Mr. H. Beasley. The cape, which had hitherto not been recorded, was presented to Admiral Otto von Kotzebue, of the Russian frigate *Rurik*, by Namehana, wife of Kamehameha I., in 1816, and remained in the possession of the family until 1928. The cape measures 32½ inches across the top, and 27 inches in depth. It is therefore of more than average size. The main groundwork is of Red Iiwi, while the border, a double crescent, and six pointed panels along the top are all of yellow 'oo'. The second half of the six panels, as well as the semilunar details in the double crescent, are in black.

Geophagy. The interesting but obscure custom of earth-eating, which has been recorded among a number of peoples in various parts of the world, is studied by Dr. Berthold Lauffer in a monograph published by the Field Museum of Chicago (*Publication* 280, Anthropological Series, Vol. 18, No. 2). Geophagy is not a universal custom, yet it may occur almost anywhere, among civilised peoples as well as primitive tribes. Nor is it general in any particular tribe or group. It is recorded in China, Indo-China, Malaysia, Melanesia, Polynesia, Australia, India, Burma, Siam, Central Asia, Siberia, Persia, Arabia, Africa, Europe, and America. Not every kind of earth is eaten; colour, odour, flavour, softness, and plasticity determine the choice. The most important from the point of view of edibility is the so-called diatomaceous earth or kieselguhr, known as 'fossil meal', 'mountain meal', or in China 'stone meal' or 'earth rice', which resembles chalk or clay and consists of siliceous remains of very minute aquatic organisms or diatoms. Earths used for medicine or enjoyment are fine, fat, and usually ferruginous clays. They are consumed in their natural state or lightly baked. Although geophagy has been characterised as a vice or depraved appetite, this is meaningless. Earth is eaten as a substitute for food in time of scarcity, as a relish, medicinally as by pregnant women, or as a part of a religious rite. In practice it appears to have nothing to do with climate, race, creed, culture areas, or higher or lesser degrees of culture. Dr. Lauffer gives a great many new facts which have escaped previous investigators, and the Chinese and American data are fully treated for the first time.

Coloration of Insects and Plant Pigments. Well-known experiments by Poulton, Linden, and others appeared to have proved definitely that green and yellow colours of caterpillars are due to the absorption of plant pigments in the intestine. Later investigations suggested that at least certain insects are able to produce green pigments synthetically. The whole problem has now been very thoroughly revised by P. F. Meyer, who has published an interesting and well documented account of his experiments (*Zeitschr. vergl. Physiol.*, vol. 11, 1930). He experimented with caterpillars of various species, which were raised on white bread, with or without the addition of the respective plant pigments, and the hæmolymph was then examined chemically for the pigments. It was found that neither chlorophyll nor any of its products is absorbed in the intestine of insects, and the green pigment in the hæmolymph of insects has no relation to chlorophyll, but represents an oxidation product of a protein. Carotin was found in the hæmolymph, but it was present in the caterpillars bred on food free of carotin as well. The experiments proved also that the absence of chlorophyll and of carotin in the food did not affect the coloration, growth, or reproduction of the insects.

Colloidal Particles in Water as Food for Mosquito Larvæ.—Larvæ of *Anopheles* obtain their food mainly by filtration of water through their highly specialised mouth-parts. It was usually thought that in this way only certain Protozoa, algæ, and generally particles not less than 5μ in size are ingested and serve as food. Investigations carried out by N. K. Shipitzina in the Zoological Laboratory of the University of Perm (*Bull. Biol. Institute*, Perm Univ., **7**, No. 4) prove that the larvæ are capable of catching and retaining even colloidal particles, as for example, those of collargol, Chinese ink, and carmin. Larvæ of all stages placed in water with the above substances in colloidal solution filled their guts with them. This shows that their filtering apparatus is a kind of ultra-filter capable of retaining colloidal particles. The retention is not selective and any particles suspended in water are collected in the gut. Experiments with rearing larvæ in pond water without any other food except the colloidal substances proved that they can develop only up to the fourth stage, when they died.

Physiology of Digestion in *Sabella*.—Edith A. T. Nicol (*Trans. R. Soc. Edin.*, **56**, 1930) describes in detail the branchial crown of *Sabella pavonina*, a tube-dwelling polychæte which occurs in estuarine mud in great numbers in some localities. The pinnules of this crown are ciliated and cause a current of water to flow between the filaments. Particles in suspension are caught by the cilia and carried to a groove on each filament, down which they pass to a pair of basal folds. Here they are sorted into three grades according to size; the largest particles are carried to the palps and rejected, the medium-sized are carried to a pair of ventral sacs and stored there until required for tube building, and the finest particles are conveyed to the mouth. Particles from the ventral sacs are mixed with mucus, laid, like a rope, along the edge of the tube, and cemented into place by the mucous secretion of the first body segment. The fine particles, including flagellates, algal spores, and diatoms, pass into the gut. The food takes an average of twenty-two and a half hours to pass through the gut at 16° C. The enzymes present in the gut are an amylase, a protease, and a lipase. The reserve materials are stored in the body as fat and glycogen; the latter occurs in large quantities in the eggs but not in other tissues. An account is given of the anatomy and histology of the branchial crown and of the alimentary tract.

Effect of Sunlight on Aquatic Organisms.—In the *Canadian Journal of Research* (Vol. 3, pp. 104-106; 1930) Dr. A. Brooker Klugh gives data of experiments to study the effect of the ultra-violet component of the sun's light on certain aquatic animals which live at or near the surface of the sea or in shallow fresh water. Dr. Klugh dealt with young eels (*Anguilla rostrata*), an amphipod (*Gammarus locusta*), and a ctenophore (*Bolinopsis infundibulum*) which lives near the sea surface. Under the filter transmitting ultra-violet light only, eels were killed in 18-24 hours; amphipods, young and adult, in 2-4 days; and the ctenophore appeared little affected. These results were in marked contrast to those previously published for animals which live at some considerable depth in the sea or come to the surface only when the illumination is very weak; such forms were readily killed by exposure to ultra-violet radiation. In the experiments three filters were used, the first transmitting both the visible and the ultra-violet regions, the second only the visible, and the third the ultra-violet only.

Venom of an Australian Snake.—In the Cape York Peninsula, one of the two most common venomous

snakes is *Pseudechis australis*, from a living example of which was obtained the venom used in experiments described by C. H. Kellaway and Donald F. Thomson (*Australian Jour. Exp. Biol. and Med. Sc.*, vol. 7, p. 133). The venom was collected weekly, and gave a low yield during sloughing, and a high yield after the snake had fed when sloughing was over. Its secretion is a relatively rapid process. Subcutaneous injections were made in sheep, monkeys, cats, rabbits, guinea-pigs, rats, and mice, and the assured lethal dose varied from 3·0 mgm. per kgm. weight of the animal, in mice, to less than 0·6 mgm. per kgm., in sheep. The poison has a powerful hæmolytic action and a more marked anticoagulant action than the venom of any other Australian snake. There is little evidence of any neurotoxic action, the only hints of such action being afforded by the ptosis which occurs as an early symptom in monkeys, the effects on the blood pressure of rabbits, and the failure of respiration which in some species is the final event following its injection. Unlike most Australian venoms, it has a striking action on the heart muscle. Possibly the venom contains a hæmorrhagin; but even if present, this plays no striking part in causing death.

Caribbean Land Molluscs. A short expedition to the Caribbean islands, made by the yacht *Mary Pinchot* between April 16 and 27, resulted in the collection of a series of land molluscs, of which twenty-seven are regarded by Henry A. Pilsbry as new forms (*Proc. Acad. Nat. Sci. Philadelphia* vol. 82, p. 221; 1930). Of the general results of the analysis of this collection the most striking is that 78·26 per cent of the shells from Grand Cayman are Jamaican in their affinities. The possible explanations are either that Grand Cayman was formerly a block of a greater Jamaica, or that the fauna has been carried across the intervening sea from Jamaica by hurricanes or by the ocean current. Both suggestions meet with difficulties. There is no definite set of current in the direction required, even if the molluscs were adapted for marine transport, which some are not. Transportation by birds has been observed in the case of *Succinea*, and *Cerion* and *Helicina* may have been carried by ocean currents, but the most credible explanation of the high similarity is that Grand Cayman, never connected with Cuba, which has a different assemblage of molluscs, had a land connexion with Jamaica in early Tertiary times.

Chromosome Numbers in certain Legumes. A cyto-taxonomic study of the related leguminous genera *Medicago*, *Melilotus*, and *Trigonella* has been made by Prof. J. R. Fryer (*Can. Jour. Research*, Vol. 3, No. 1). The number of chromosomes and their morphology has been recorded for 25 species of *Medicago*, 4 of *Melilotus*, and 3 of *Trigonella*, from a study of the root tips. The chromosomes are grouped as of six lengths, ranging from about 5 μ to 1 μ. All the chromosomes of each species are usually of the same size in some sections of the genus *Medicago*, but in the subsection Pachyspiræ there are usually two sizes present in the chromosome group. Satellites are also present on certain chromosomes, and tetraploid cells or sectors sometimes occur in otherwise diploid roots. In *Medicago* the somatic numbers found are 14, 16, and 32. The same numbers have been found in different species of the related genus *Trifolium*. In the genera *Melilotus* and *Trigonella* the only number found was 16. The Falcago section of *Medicago* contained some species with 16 chromosomes and others with 32, suggesting that the tetraploid species may have arisen directly from related diploid species. There is found to be no relation between tetraploidy and the perennial habit, since some diploids are perennial and some tetraploids annual. Both diploid and tetraploid strains were found in *Medicago falcata*, and reasons are given for regarding *M. media* as a hybrid between *M. sativa* and *M. falcata*.

Origin of Coal. – A readable and well documented account of recent work upon this question will be found in the *Naturwissenschaftliche Umschau* of the *Chemiker-Zeitung*, **19**, No. 9/10, by Dr. Fritz Rosendahl. Coal obviously arises from plants, and the different types of plants responsible for lignite and coal respectively can, to a considerable extent, still be recognised by the microscope. But, although attacked in various ways – by analysis of the end products in the earth, by laboratory experiments upon the behaviour of present-day plants when left to decompose under various conditions, etc. – the factors responsible for the production of peat, lignite, and coal are still in dispute. It now seems fairly clear that cellulose constituents disappear before the lignin constituents in the plant walls; fatty and waxy deposits such as plant cuticles, probably vary in importance in different deposits, varying particularly with the content in these substances of the original plant material. Lignite and coal have probably developed from peat-like deposits, and Dr. Rosendahl makes it clear what an important influence the theories of Taylor have had upon recent developments in investigation of this subject. Taylor has directed attention to the great influence the nature of the mineral covering layer will have upon the further chemical changes proceeding in buried deposits of peat-like plant material.

Geology of the Shetlands. Continuing his investigation of the Old Red Sandstone of the Shetlands, Dr. T. M. Finlay describes in the *Trans. Roy. Soc. Edin.*, Vol. 56, Pt. 3, No. 27, 1930, the sedimentary and igneous rocks lying to the west of the metamorphic series that forms the backbone of the islands. The sediments turn out to be quite unlike those of the same system from other areas, partly because of the metamorphism they have suffered and partly because they represent fine grained sediment slowly accumulated in a deeper basin. Plant remains are the only fossils, and they are quite untrustworthy for detailed correlation. The assemblage of igneous rocks, however, bears so close a resemblance to those of the Lower Old Red Sandstone in Scotland that the balance of evidence supports the view that here, too, the rocks are of the same age. Andesitic lavas and tuffs underlain by rhyolite and basalt are strongly developed. This volcanic phase is succeeded by an intrusive complex ranging from gabbro to granite. A third phase is represented by dykes of three series; the earliest is lamprophyric; the second is of quartz-porphyry, chilled against the first and including xenoliths derived from them; the third consists of highly acid granophyres containing spherulites with fibres of riebeckite. It is suggested that those latest dykes may possibly be of Tertiary age.

Production of Low Temperatures. The apparatus usually employed to produce liquid hydrogen is elaborate and costly, with the result that it is available for low temperature researches in very few laboratories, although quite small quantities of liquid would often suffice. A small and inexpensive liquefier is described by M. Ruhemann in the *Zeitschrift für Physik* for Oct. 8, which, it is claimed, can be assembled in a few days by any laboratory workshop. It operates on the Linde principle, hydrogen drawn at high pressure from a cylinder, after purification, being first circulated through a tube immersed in liquid air, and then subjected to valve expansion with

regenerative cooling in the usual way. The main part of the system is supported in a Dewar flask. The temperature of liquid hydrogen (20° absolute) is attained in from five to eight minutes with an initial pressure of rather more than 100 atmospheres and a flow of a few litres per second, whilst liquid helium can be equally readily produced if liquid hydrogen is available in quantity. The use of the apparatus is obviously limited by the small volume of the vessel into which the valve opens, but, with this restriction, it makes the production of very low temperatures feasible in any place when liquid air can be obtained.

Variation of 'Flashover' Characteristics.—The use of a pressure of 132,000 volts for the transmission of electric power on the English network has brought prominently to the front many new problems in connexion with high voltages. In *World Power* for November, S. Whitehead and W. D. Owen discuss the influence of altitude on the flashover characteristics of electrical equipment. It is well known that sparks occur more readily between electrodes the smaller the density of the surrounding gas and the higher its temperature. At high altitudes also, the brush discharge, which is called the corona and is due to the high electric pressure, makes its appearance more readily. The authors discuss the formulæ from which the flashover and corona can be predicted and state that they give accurate results. The standard density and temperature of the atmosphere in engineering work is 760 mm. and 25° C. respectively. Experimental results for sparkover and flashover are reduced to this standard density and pressure. It is pointed out that this temperature is too high for general use in Great Britain. For rating machinery it is most convenient to use the standard conditions at sea-level. But the mean sea level temperature is only 11° C., and this introduces a four per cent error in the rating. They suggest that this temperature should be taken as the standard. It is important that the rating of all the machinery and devices for very high voltages should be done for the same temperature.

Low Temperature Oxidation.—Some experiments on the lag in ignition (the interval of time between the rapid heating of a combustible mixture to, or above, the ignition point and the appearance of flame) in the case of mixtures of hydrocarbons and air are described by J. S. Lewis in the October number of the *Journal of the Chemical Society*. The lag may, in certain cases, terminate in rapid oxidation unaccompanied by flame, examples of which are given in the paper. The experiments were conducted in glass bulbs of 125 c.c. capacity with a long narrow neck, which were maintained at the desired temperature, and the liquid introduced in small wide-mouthed tubes of thin glass. Experiments with petrol freed from aromatic hydrocarbons showed that removal of the lighter constituents caused an appreciable drop in lag and in ignition temperature, and such fuel would probably 'knock' more readily. The effects of powdered glass, charcoal, metals, etc., were studied.

Replacement of Castings by Weldings.—In a paper read before the Institution of Welding Engineers on Oct. 16, Mr. P. L. Roberts discussed the possibilities of replacing iron castings by welded structures built up from rolled steel. Among the advantages which are claimed are an increase of strength of 2·5 times or a corresponding reduction of weight; economies in material used, in the workshop accommodation required, and in machining, the latter being due to increased accuracy of dimensions. Among the examples given the two extremes may be mentioned. In the first case a casting weighing 1750 lb. was replaced by a 'welding' the weight of which was 850 lb. The cost per lb. was much the same in each case, with the result that a saving of 52 per cent was effected. The largest part recorded was a casting weighing 16,000 lb. The corresponding welding weighed only 9300 lb. and cost but a little more per lb. In the aggregate a saving of 32 per cent was obtained. The greatest saving, 66 per cent, was effected on a part which as a casting weighed 5576 lb. and as a welded structure but 1920 lb. It is pointed out that if welded parts are to be as economical as possible, their design should be treated *ab initio*. The mere modification of the design of the casting means the retention of many features—such, for example, as arrangements for coring and withdrawal from the mould which, though necessary in the casting itself, are of no importance in the welding.

Preparation of Catalysts.—Dr. R. Dankoff, of the State Physical-Technical Institute, Leningrad, has sent us a communication on this subject. The method he uses consists in depositing metals from the vapour form on cold surfaces, since it was expected that such surfaces should possess a very fine structure and great capacity for adsorption. Previous experiments of Gauger with nickel and platinum so deposited, with a mixture of ethylene and hydrogen, showed that no reaction occurred, but Dr. Dankoff states that deposits of nickel, platinum, and iron produced by condensation in vacuum of 10^{-5} mm. on glass at 0° C. showed considerable activity. No great variation in the results was found with metals deposited at −180°. A mixture of hydrogen and ethylene introduced into the apparatus reacted energetically at 0°, in the case of nickel two-thirds of the mixture reacting during the first minute. The initial pressure was 55 mm., the volume 200 c.c., and the catalyst surface 100 cm.^{2}. Platinum was more active, iron less active, than nickel. In the case of nickel a dependence on the thickness of the deposit was found, indicating the porous character of the surface, as found in adsorptive experiments. A curve accompanying the communication shows the dependence of the rate of reaction on the thickness of the layer expressed as the number of layers of atoms in the deposit, but it is not suitable for reproduction.

Hydrolysis of Di- and Poly- Saccharides.—The determination of the relative ease of hydrolysis of disaccharides and of polysaccharides such as starch and cellulose has recently received attention by several experimenters. Since the structure of cellulose as a long chain of cellobiose units is now established on a reasonably firm basis, and since it may be assumed that starch is presumably derived in a similar manner from maltose, the interrelation of the reactions involving both the analysis and synthesis of these products is of interest. In the October number of the *Journal of the American Chemical Society*, Hibbert and Percival describe the hydrolysis of cellulose, cellobiose, cellodextrin, starch, inulin, and levan (from the action of *B. mesentericus* on sucrose), using zinc chloride dissolved in hydrochloric acid as a medium. A single unimolecular velocity constant is assumed. It is concluded that the slow hydrolysis of cellulose is, in a large part, due to the slow hydrolysis of cellobiose; that cellobiose is not a reversion product; and that there seem to be no grounds to suppose that starch and cellulose are essentially different, except for the α-linkages in the former and the β-linkages in the latter. The rates of hydrolysis of sucrose, levan, and inulin in 0·1 N oxalic acid at 65° are almost the same, and it is concluded that this behaviour is related to the γ-fructose residue present in each.

The Antiquity of Civilised Man.

THE Huxley Memorial Lecture for 1930 of the Royal Anthropological Institute was delivered on Nov. 19 by Prof. A. H. Sayce, who took as his subject "The Antiquity of Civilised Man".

One of the leading obsessions of the historian has been the belief in the recent evolution of civilisation and the shortness of the period during which it has endured, an obsession derived from medieval tradition. Another tradition derived from medieval belief was that of the decline instead of the progress of civilisation and culture. The belief in a 'Golden Age' had been fostered by the manifest relapse into barbarism which characterised medieval Europe. Civilised man, it was held, had had but a brief existence, and the documents which ascribed to him an earlier date were unworthy of credence. The heroes of the old legends became 'solar myths' and 'the ancient empires of the east' were stripped of their antiquity.

A new era has dawned upon us. The scientific method, aided by the spade, has opened up a new world and furnished us with facts instead of theories. The result is that the story of the antiquity of man which is being told by geology is being retold of civilised man by archaeology. The age of civilised man must be pushed back through the centuries like the age of uncivilised man. The last hundred years have unfolded a new world—that of the civilised past.

Historical Egypt now has its lessons to teach us. While the literary historians have been vying with one another in the endeavour to minimise its antiquity, the spade of the excavator has made discoveries which have rightly been termed revolutionary. At Saqqara Mr. Firth has laid bare a complex of buildings without parallel anywhere else in the country. In the art and architecture of these buildings, and in the work of artists of the Third Dynasty in the time of King Zoser, described so recently as 1895 as a 'mythical' king, Egypt would seem to have reached its climax. Architecture, art, and glazed tiles all testify to long centuries of development which must have preceded the period of perfection to which they belong. The same impression is made upon us when we come to examine the hieroglyphic script. It is already as complete and conventionalised by use as in the days of Rameses and Darius. The alphabets are there by the side of the syllabary and ideographs; and there are indications that the hieratic or cursive hand was already employed. The smaller objects of daily life the furniture of the house, the jewellery and garments that were worn, or the articles of the toilet the discoveries made by Dr. Reisner in the tomb of the mother of Kheops prove that at the beginning of the fourth dynasty the culture and art of Egypt were still at their highest level.

When we turn to Babylonia, there also the latest discoveries have pushed back the highest development of its art yet known to us to an undetermined but remote antiquity. Hitherto ancient Babylonia, whether Sumerian or Semitic, has seemed artistically deficient and inferior; its inhabitants were primarily men of business and trade, the initiators of banking and international commerce, but with little artistic sense. The Royal and other tombs found by Mr. Woolley at Ur have revolutionised our judgment on this matter. The gold and silver work, the inlaid designs in shell, have revealed an art of the first order. Yet the tombs and their contents actually belong to Babylonian pre-history rather than history. The few inscriptions found with them are not yet in the fully developed cuneiform or linear script which already had a long history behind it when Sargon of Akkad founded the first Babylonian empire in 2700 B.C. They are in fact still the pictographic designs out of which the first semi-linear and then the cuneiform signs developed. With them goes another remarkable fact. This advanced art and culture exhibited in the tombs is accompanied by human sacrifice on a vast scale, which reminds us of Dahomey rather than of the Near East. Human sacrifice was not only unknown in historical Babylonia, but also its very existence in any period of the past history of the country was ignored. Yet the Royal tombs by no means belong to the earliest period of Babylonian history. Mr. Woolley tells us of five further layers all necessarily older than the cemetery into which the Royal tombs were sunk. By them we are taken back to the times when the alluvial plains of Babylonia were only beginning to be formed at the head of the Persian Gulf.

It may be that the Royal tombs of Ur, modern as they are when compared with the strata below them, belong to a pre-Sumerian time and a pre-Sumerian race. The Sumerian people called themselves "the black headed race". This implies that there was also a blond race in the country, an inference confirmed by the fact that Sumerian art represents them as broad skulled, whereas most of the early skulls discovered at Ur and examined by Sir Arthur Keith prove to be dolichocephalic. On the Egyptian monuments the Amorites of Palestine are depicted as blonds with fair hair and blue eyes. In these blond Murru we must see the Mesopotamian Mitannians of later history, the Murrian or Amorite predecessors of the Sumerians. At Tepe Gawra Dr. Speiser has discovered two strata of cultural remains below the stratum which belongs to the Bronze age and the appearance of the Sumerians. In this last the copper objects resemble those found at Ur and El Obeid, which are dated to the period of the first dynasty of Ur (about 3100 B.C.), whereas the earlier strata ta[ke] us back to the aeneolithic period and the painte[d] pottery of Jemdet Nasr.

The tombs of Ur, however, testify to more than an advanced art and human sacrifice. They indicate a wide international trade and the working of mines. Gold, silver, and lapis lazuli are all found in them in profusion as well as copper. Gold came from the Persian Gulf, but silver was probably brought from the mines of the Taurus. This fact is in harmony with the discoveries recently made in China and north-west India. Both at Mohenjo-Daro and at Harappa a civilisation has been brought to light which was in close touch with Elam and Sumerian Babylonia. In China, Prof. Andersson has found painted and polished pottery of the neolithic and chalcolithic age which is related to the neolithic pottery discovered in Susa; similar ware has been found in Babylonia and at Sakche-gozu, north of the Gulf of Antioch; while the recent excavations of Prof. Li at Yin in Honan have shown not only that the Shang Dynasty (1766 1154 B.C.) was historical, but also that the account of its sculpture and script, with the long preceding development and commercial intercourse implied by them, was based on fact.

point to the Third Dynasty of Ur (2400 2300 B.C.).

It is unnecessary to dwell upon the length of time presupposed for the rise and development of all this trading activity, with the means of traffic and use of writing which it implies. Civilised man is far older than the purely literary scholar has dreamed.

Caledon Meeting of the South African Association for the Advancement of Science.

THE twenty-eighth annual meeting of the South African Association for the Advancement of Science was held at Caledon on July 7-12, 1930, under the presidency of Mr. H. E. Wood, Union Astronomer. The meeting was well attended and eighty-two papers were read. The South Africa Medal and grant were presented to Dr. A. L. du Toit at the close of the presidential address. A popular illustrated lecture was given by Dr. G. H. Skaife on heredity. There was a reception by the Mayor and councillors and visits to various places of interest in the neighbourhood.

The presidential address by Mr. H. E. Wood was entitled "Recent Astronomical Developments". In it he pointed out that astronomical observatories throughout the world are about to combine to redetermine the mean distance of the sun from the earth, the unit in terms of which all astronomical distances are measured. This is being undertaken now because the minor planet No. 433, Eros, makes a near approach to the earth early in 1931. Mr. Wood also indicated that in many cases he enumerated, while the actual object has not been attained, many other highly important astronomical discoveries have resulted. Problems of the determination of the distances of the stars were discussed and the various methods compared. The constitution of interstellar space in the light of recent work was described. Recent advances in knowledge of the nature of light and Millikan's work on high frequency radiation were noted. The address closed with a review of man's conception of the universe at various stages of his history.

The presidential address to Section A was delivered by Prof. H. H. Paine, who dealt with "The Motion of Ions and Colloid Particles in an Electric Field". The alliance of physics, chemistry, and mathematics was indicated, with a possible extension to biology. Research in electrical specific conductivity of solutions was discussed, as were the possible effects of neighbouring ions on each other's mobilities. The rôle of the ionic atmosphere and the work of Debye and Hückel were set forth. Onsager's work, eliminating the use of Stokes's law for the movement of ions, and the Brownian movement of ions were discussed. Evidence was given from personal work that the initial rise in mobility so often observed is due to the residual electrolyte impurities in a colloidal solution. The analogy between ions and colloidal particles, so far as their electrical structures are concerned, was the chief argument of the address.

Prof. W. F. Barker chose "Some Effects of Light" as his presidential address to Section B. He first set forth the relationships of the various kinds of radiation and the effect of the excited atom or molecule. Photochemical processes were discussed in relation to photography, vision, and carbon assimilation in plants. The photochemical association in rhodopsin was briefly outlined. The far-reaching importance of photosynthesis of plants was indicated. The synthesis of sugars by plants and the decomposition products of activated carbonic acid, especially the possible intermediate production of formaldehyde, were discussed. The work of Baly, Porter, and Ramsperger was analysed and the importance of surface reactions indicated. The reactions of activated formaldehyde with simple inorganic nitrogenous compounds, with the synthesis of proteins in the daytime and their transport at night, probably as asparagine, were discussed. The nitrate supply as the limiting factor in the synthesis of proteins in plants and the practical application to the fertiliser problem were indicated. The chemistry of chlorophyll and vitamins was described and also the effects of ultra-violet light on living organisms.

The president of Section C, Dr. E. P. Phillips, gave "A Brief Historical Sketch of the Development of Botanical Science in South Africa and the Contribution of South Africa to Botany" as his address. It comprised a review of botanical progress over two hundred and fifty years. Three periods were set forth. The first commenced with the early botanical collectors from the Cape, to the time of W. H. Harvey and his "Genera of South African Plants". At the close of this period, about 1868, the first South African botanists appeared, and the second period, ending about 1903, was marked first by quiescence and then by renewed activity. The third period, from 1903, marked the development of botanical science in the universities. The collectors, botanical literature, and trends of each period were detailed. The first period was marked by much taxonomic work and at its end by publications. The second period saw great extension of this work, and the influence of Bolus at the Cape and of Medley Wood in Natal was marked. The activities of many other collectors were detailed and the vast amount of work on systematic botany and plant geography indicated. The third period, from 1903 onwards, was marked by university developments, plant biology studies, economic botany in many phases, plant embryology, and the institution of the Union Botanical Survey.

"Some Aspects of Bird Life" was chosen by Dr. E. L. Gill as his presidential address to Section D. Adaptations were discussed. It was pointed out that the reaction against adaptation to environment has almost certainly overshot the mark, though correlation of structure and way of life are not necessarily close. Wading birds were discussed in relation to their feeding habits, bills, and legs. The avocet's turned-up bill "may be the result of some phase of racial pathology perhaps not just disastrous enough to lead to the extinction of the stock". Plumage and its relation to flight were also discussed. The subject of subspecies and races of birds was introduced and the time-factor for the development of subspecies indicated with reference to Moreau's work on crested larks in Egypt. Bird behaviour and patterns of behaviour in courting, play, and leisure were noted, and migration of birds as affecting South Africa discussed. South Africa has few islands and on the mainland dispersal is rapid. South Africa is the terminus for the great migrations from the far north. Great numbers of European birds winter at the Cape, and many African birds come to breed and then return to tropical Africa for the southern winter. The movements of the purely African birds are still largely a mystery. The birds of the Southern Ocean need more investigation—a matter of difficulty. The physiological effect of migration and the unknown stimulus that moves birds to such unaccustomed feats of endurance were also mentioned.

The subject of "South Africa's Place in Prehistory: A Plea for Organised Research and the Better Preservation of Historic Remains", formed the presidential address to Section E given by Mr. C. van Riet Lowe. The early history of archaeology was briefly reviewed, the South African work dating roughly from Dale, 1866, since when a number of workers have appeared. The reasons for differences in nomenclature in South African and European cultures were detailed, and also the relationship of European and African Stone Ages. The importance

of geology and geography in relation to ethnology was stressed. Various aspects of African prehistoric art were detailed and stress laid on the value of rock engravings or petroglyphs, the evolution of numerous styles and four probable successive phases being outlined. The need of correlation of all associations and of detailed search for such associations was urged. The address concluded with an appeal for greater study and better preservation of archæological objects.

"Some Problems of the Transition from Subsistence to Money Economy" was the subject of the presidential address of Mrs. M. Palmer to Section F. The transition is inevitable and many South African natives are now in the transition stage. The conservatism of subsistence economy is because of its guidance by customs and absence of markets, competition, and profits; and communal tenure of land is correlated with such economy. The social and economic reactions to be expected under the extremely rapid transition in the African and eastern areas of the world were discussed. Private ownership of land has caused misunderstandings repeatedly among primitive peoples and the commercial use of land is incomprehensible to them. The widely divergent accounts of the economic position of the native were explained. Even when individual peasant tenancies are established, an unemployment problem appears in the second generation. Commercial agriculture requires commercial development to balance it. The teaching of primitive crafts by out-of-date means to natives was deplored, for it gives them false ideas of successful livelihood that cannot materialise in competition with machinery. Artificial means of inducing natives to take up wage-labour have been necessary, and taxation and organised recruiting have supplied these. At first the native, who only works in town about half the year, separated from his land and family, regards wages as tax money or as a means to luxury. Later, as his needs increase, subsistence in the reserve largely disappears and his town wages are his real support. Under such conditions, under-cultivation of the reserves, inefficient and casual labour, a lessened market for the products of industry, and numerous evils due to lack of supervision and separation of families result. The system of 'native treasuries' and of co-operative credit societies was explained and recommended as a great aid in bridging this transition period.

In Section A, meteorological work in the Transvaal and in Mozambique was described. The effects of oil on the coefficient of restitution and the electrical field of the atmosphere are of interest to physicists; astronomers dealt with the origin of meteorites and the apparent orbit of a spectroscopic binary. A new method of deducing borehole capacity was propounded; and the veteran mathematician, Sir Thomas Muir, made his tenth contribution to the bibliography of determinants.

In Section B, soil chemistry in connexion with the potash requirements of South African soils, base exchange in the Malmesbury shale series, soil acidity, sticky point water, and hard pan formation produced a number of papers. Slangbos oils and the antimony electrode were discussed. The state of natural water supply and the effect of destruction of vegetal cover received serious consideration, as did also a paper on the medicinal waters of South Africa in international measurements.

In Section C, systematic work on the Virosæ division of the Euphorbiaceæ, on new *Liliaceæ*, Hydrocharitaceæ, Dianthaceæ, and Lobostemon was detailed by various workers. Economic botany was represented by work on barley diseases, South African fungi, root nodules, abnormalities in the composition of oranges and seed formation in pears, and effects of fire on biotic communities. Ecological work dealt with 'Gifblaar' (a stock poison), flora of a lamsiekte farm, bush groups, and floras of individual areas. The physiological side was represented by work on hydrolysis in the vine and the influence of soil water around roots on the hydrogen ion concentration of tracheal sap.

In Section D a number of interesting topics were discussed. A series of papers by members of the University of Stellenbosch dealt with Amphibian osteology, osteogeny, and ontogenesis in regard to various forms, including *Heleophryne*, and there was discussion of Noble's dictum in relation to the latter form. Ecological notes were given on the Acrididæ of the Cape Peninsula. Seasonal variation in the coat of common domestic mammals and density in variation of the fleece of the merino are of economic importance. Animal ecologists also dealt with the methods of studying numbers of terrestrial animals and numbers of tsetse fly in Tanganyika Territory. A modification of the rapid agglutination test, of use to the veterinary profession, was set forth. Descriptions were given of a number of new species of Protozoa, including new and economically important Myxosporidia of fish and new Protoopalinidæ. Cases of physical inheritance and of racial admixture, including Chinese crosses with various natives and Indians, were described. Variations in the skulls of vervet monkeys, ovine schistosomiasis, and social hydrology were also discussed, and a morning was devoted to a discussion on provision for marine biology. The centenary of the death of Lamarck was commemorated.

In Section E a human skull was described. The chronology of the Mossel Bay industries was detailed and illustrated, as were implements found in a cave at Tafelberg Hall. Interesting accounts of cattle magic and medicines in Bechuanaland and of Bantu customs in relation to widowhood and lobola formed important contributions to social anthropology.

In Section F, the historical side was interestingly represented by short papers on an eighteenth century MS. on agricultural improvement at the Cape and on the first leper settlement in South Africa. The psychology of mysticism and of personality were discussed, and a reasoned account of the psychological factors affecting the attitude of black to white was presented. The crisis in our present civilisation was given a fine exposition. The progress of Portuguese children in Lourenço Marques and in Portugal were compared.

The next annual meeting of the Association will be held in July 1931 at Grahamstown, under the presidency of Prof. J. W. Bews, professor of botany at the Natal University College, Pietermaritzburg, Natal.

H. B. F.

University and Educational Intelligence.

CAMBRIDGE. - J. C. P. Miller, of Trinity College, has been elected to an additional Isaac Newton Studentship tenable for one year.

The General Board has recommended that a readership in statistics shall be established as from Jan. 1 next, and that it should be authorised to appoint as first holder of the readership Mr. G. Udney Yule, of St. John's College. It is recommended that the readership shall be assigned primarily to the Faculty of Agriculture and Forestry.

The Faculty Board of Archaeology and Anthropology has appointed C. B. Humphreys, of Christ's College, to

be honorary keeper of the Melanesian Collection in the Museum of Archaeology and Ethnology.

The Gedge Prize for original observations in physiology has been awarded to H. Barcroft, of King's College, who gained first-class honours in the Natural Sciences Tripos Pt. II., 1927.

LONDON.—The following doctorates have been awarded: *D.Sc. Degrees in chemistry* on K. R. I. Krishnaswami (University College) for a thesis entitled "A Revision of the Atomic Weight of Tantalum" (*Jour. Chem. Soc.*, June 1930), and (2) "The Atomic Weight of Antimony from different Sources" (*Jour. Chem. Soc.*, 1927); and H. L. Riley (Imperial College—Royal College of Science) for a thesis entitled "Studies in Complex Salts" (*Jour. Chem. Soc.*, 1928–30, *Phil. Mag.*, 1924, 1927). *D.Sc. Degrees in physics* on J. H. Brinkworth (Imperial College—Royal College of Science) for a thesis entitled "On the Measurement of the Ratio of the Specific Heats of Gases" (*Proc. Roy. Soc.*, 1925, 1926, 1930); and Prof. H. Dingle (Imperial College—Royal College of Science) for a thesis entitled "The Successive Spectra of Fluorine" (*Proc. Roy. Soc.*, 1926, 1928, 1929, 1930). *D.Sc. Degree in zoology* on H. Mukhopadhyay (Imperial College—Royal College of Science) for a thesis entitled "On the Development of the Vertebral Columns of Urodela and Anura" (*Phil. Trans.*, 1930). *D.Sc. Degree in geology* on G. Sheppard, for a thesis entitled "The Geology of South-West Ecuador", together with thirteen subsidiary contributions.

PROPOSALS have been made for the formation of an Association of Examiners for the adequate discussion and ventilation of the problems with which examiners are faced. It is suggested that the inaugural meeting be held early in January. Further particulars and information may be had from Mr. B. C. Wallis, 345 Stag Lane, London, N.W.9.

REFERRING to the note in NATURE of Nov. 15, p. 791, we are informed that while it is true that Prof. R. Robinson (Oxford) has received an invitation to act as the non-resident lecturer on the George Fisher Baker Foundation of Cornell University during the second term of the academic year 1933–34, he has not yet intimated his acceptance of this invitation.

THE Harvard Engineering School is offering this year a new course on vibration problems, a subject which is growing in importance in the design of high-speed machinery, although it has been neglected in most American engineering schools. The course will deal mainly with the physical and mathematical basis of mechanical vibration and is being given by outside lecturers, Messrs. J. Ormondroyd and A. L. Kimball, the general direction of the course being under Prof. Arthur E. Norton, of the Harvard Engineering School. Mr. Ormondroyd is manager of the Experimental Engineering Division of the South Philadelphia Works of the Westinghouse Electric and Manufacturing Co., and has had wide experience in vibration problems. Mr. Kimball is Associate Head of the Mechanics Section of the General Electric Company Research Laboratory at Schenectady; he has made a special study of photoelastic methods of stress analysis and is an authority on vibration damping.

A PRELIMINARY programme has been issued of the nineteenth annual Conference of Educational Associations, to be held at University College, London, W.C.1, on Dec. 31–Jan. 7, under the presidency of Sir Richard Gregory, whose presidential address, entitled "The Worth of Science", will be delivered on the first day of the Conference. Among the papers and discussions arranged are the following: Learning how to study, by Prof. T. H. Pear (British Psychological Society—Education Section); efficiency of first school examinations and their relation to matriculation, by Sir Philip Hartog (New Education Fellowship); "The Beauty and Wonder of the World", by Sir Arthur Thomson (School Nature Study Union); vocational guidance, by Dr. Macrae (Training College Association); individual work in mathematics, by Mr. G. W. Spriggs (Dalton Association); discussion on experimental phonetics, Prof. E. W. Scripture and Prof. P. Menzrath (Modern Language Association); educational handicap of the deaf from the psychologist's point of view, by Dr. J. Drever (National College of Teachers of the Deaf); and a joint conference on the teaching of geography, at which the speakers will include Sir Richard Gregory (chairman), Mr. J. Fairgrieve, Sir William Furse, Miss B. Hosgood and Mr. C. B. Thurston. Exhibitions of books, handwork, and school equipment will be open during the Conference, the B.B.C. is arranging a lecture and demonstration on school broadcasting, and Prof. Winifred Cullis is giving a lecture demonstration on teaching biology by wireless. Full particulars of the Conference can be obtained from the Secretary, Miss M. A. Challen, 29 Gordon Square, London, W.C.1.

Historic Natural Events.

Nov. 30, A.D. 60. St. Paul's Storm. St. Paul, being carried for trial at Rome, was taken on board a ship at Cæsarea. The ship touched at Sidon and was then forced by northerly winds to pass south of Cyprus to the south coast of Crete. By this time "the Fast was already past" [probably that of Expiation, Sept. 25], and Paul advised the master of the ship to winter in harbour. This advice was disregarded, however, and the ship set out for a more commodious harbour. The account continues: "But not long after there blew from the shore a tempestuous wind, called Euroclydon. And when the ship was caught, and could not bear up against the wind, we let her drive." Neither the sun nor stars appeared for many days, and there was "no small tempest". On the fourteenth night, "falling into a place where two seas met", they ran the ship aground on an island called Melita, where she was broken up by the violence of the waves, but all were saved. This is believed to be the island of Malta, but Dr. William Falconer, who prepared a dissertation on the voyage, identified it with Melada in the Adriatic. The date of the shipwreck is not known accurately, but Dr. Falconer calculated that it was most probably at the end of November or beginning of December.

Nov. 30, 1645. Earthquake in the Philippines. The greatest earthquake known in the Archipelago. From Manila to the northern provinces of Cagayan and Ilocos Norte, few stone buildings escaped destruction, some native villages completely disappeared, while there were many changes in the surface features and in river-courses.

Nov. 30, 1775. Destruction of Fish. An account of the drought of 1775–76 in Sumatra (*Philosophical Transactions*, Abridged Ed., Vol. 15, p. 127) states that: "In the month of November, the dry season having then exceeded its usual period and the S.E. winds continuing with unremitting violence, the sea was observed to be covered, to the distance of a mile and in some places a league from shore, with fish floating on the surface. Great quantities of them

were at the same time driven on the beach or left there by the tide, some quite alive, others dying, but the greatest part quite dead. The fish thus found were not of one but of various species, both large and small, flat and round, the cat-fish and mullet being generally the most prevalent. The numbers were prodigious, and overspread the shore to the extent of some degrees. Their first appearance was sudden; but though the numbers diminished, they continued to be thrown up, in some parts of the coast, for at least a month, furnishing the inhabitants with food, which, though attended with no immediate ill consequence, probably contributed to the unhealthiness so severely felt. No alteration to the weather had been remarked for many days previous to their appearance. The thermometer stood as usual at the time of year at about 85°."

Dec. 1, 1607. Frost in Lake District. The Watermillock Register in the English Lake District records "a marveillous great frost which contynued from the first day of December until the 15th. day of February after. Ulles water was frozen ower and so continued from the 6th. day of December untill the 22nd. day of February followinge. So stronge that men in great companies made a common way up the same . . . with horses loaden with corne. Upon the 6th. day of January the younge folkes of Sowlby went unto the midst of the same water and had a Minstrell with them and there daunced all the after Noone. On . . . the 9th. day of February, at Weathermeallock was a Boone fire builded on the Ise and matches of Shotinges Shott. . . ."

Dec. 4, 1495. Tiber Flood.—One of the greatest floods of the Tiber, remembered as the "deluge of Rome", is described at length in a pamphlet reprinted by Dr. G. Hellmann in No. 12 of his "Neudrücke von Schriften und Karten über Meteorologie und Erdmagnetismus", with a rough wood-cut showing the flooded streets and drowning citizens. A torrent of water ran through the city, and many houses were destroyed.

Dec. 4, 1879. Low Temperature in British Isles. Throughout the greater part of December 1879, intensely cold weather was experienced. The coldest day was Dec. 4, when a minimum of −23° F. was reported at Blackadder in Berwickshire, the lowest known shade temperature in the British Isles. Temperatures below 10° F. were registered over southern Scotland and northern England as far as the Valley of the Trent, and over almost the whole of England, Scotland, and Ireland temperature fell below 20° F. Many persons were frozen to death, and evergreens were killed, including a holly nearly a hundred years old.

Dec. 5, 1922. Mirage.—At about 10.30 A.M. the lightkeeper at Cape Wrath lighthouse, in the north of Scotland, observed in the sky above a conical hill to the southward a mirage of land and sea, giving a perfect representation of the whole of the coast line from Cape Wrath to Dunnet Head, as it would have been seen from a distance of about ten miles. There were three repetitions of the mirage, one above the other, with sea separating each pair. The appearance lasted about 30 minutes, but was only visible through a telescope. It was attributed by Mr. Brunt to double refraction from two nearly vertical surfaces of discontinuity between warm and cold air.

Dec. 5, 1927. Hurricane in Pacific.—A violent hurricane struck Butaritari in the Gilbert and Ellice Islands shortly after 2 A.M.; nearly all the houses were blown down or damaged and many trees destroyed. Butaritari is in only lat. 3° N., and hurricanes so near the equator are very rare.

Societies and Academies.

LONDON.

Royal Society, Nov. 20.—**Lord Rayleigh**: Iridescent colours of birds and insects. The reflection spectra have been examined in the ultra-violet. *Morpho* butterflies and *Urania* moths show ultra-violet maxima in general agreement with the theory of interference. In *M. achilles* the blue colour is due to a reflection of the second order. No *Morpho* butterflies show their blue colour by transmission. Iridescent beetles showing a deep red colour at normal incidence may be made to pass through all the colours of the spectrum to violet, provided that arrangements are made to annul refraction at the air-chitin surface so as to obtain very oblique incidence without. Some of the golden beetles show transmission spectra of bands which vary continuously in position with the part of the specimen examined. It seems impossible to interpret this reasonably except on the theory of interference. Moist chlorine gas does not destroy the colours of *Morpho* or of *Urania*, though the black background is bleached; nor does chlorine decolorise the metallic beetles. Peacock feathers undergo a progressive change of colour in ultra-violet light or long continued sunlight, the colours becoming more refrangible. Other feathers are slowly decolorised without change of refrangibility. Fading under light or chlorine is attributed to the breaking down of an interference structure. The generalisation seems to hold good that colour which is stable in chlorine is certainly *not* due to pigments.—**C. R. Bailey, A. B. D. Cassie**, and **W. R. Angus**: Investigations in the infra-red region of the spectrum (1, 2). The infra-red absorption spectrum of sulphur dioxide has been re-examined in the region 1-22 μ with a prism spectrometer fitted with quartz, fluorite, rocksalt, and sylvine prisms. The partial resolution of most of the bands has rendered possible the determination of a number of the molecular constants, in particular the size and shape of the molecule, the moments of inertia, and the fundamental vibrational frequencies.—**J. K. Roberts**: The exchange of energy between gas atoms and solid surfaces. Experiments on the accommodation coefficients of helium with tungsten and nickel surfaces have been carried out under conditions in which the surfaces could be freed from films of adsorbed gas. The values obtained were 0·05-0·07 for tungsten and 0·08 for nickel, and are considerably lower than the values ordinarily obtained for gas-covered surfaces.—**G. N. Watson**: The use of series of Bessel functions in problems connected with cylindrical wind tunnels. Various Fourier-Bessel and Dini series are encountered in problems concerning cylindrical wind-tunnels, and the convergence of these series in certain parts of the tunnel is slow. The object of the paper is to transform these series into more rapidly convergent series in order to make it possible to compute their sums.—**A. J. Allmand** and **R. B. King**: The sorption of water vapour at low pressures by activated charcoals (1). Isothermals of water vapour have been determined for six different and typical activated charcoal specimens, at 25° C. and over a pressure range of 10^{-1} mm. down to 10^{-3} mm. Undisplaced gases on the charcoal surface cause 'drift', as in other cases. When this displacement had proceeded to its limit under the experimental conditions, the isothermals were apparently reversible. No sign of the validity of 'Henry's Law' was observed. Water vapour is apparently relatively ineffective as a displacing agent for adsorbed oxygen. Heat of adsorption increases as the quantity sorbed decreases. No definite evidence of discontinuity in the isothermals was discovered.

DUBLIN.

Royal Irish Academy, Nov. 10.—**J. J. Nolan**: The effect of water vapour on the mobilities of negative ions in air. A series of values of mobility ranging from 2·4 to 1·5 cm./sec. is found corresponding to certain favoured sizes of ions. At least two such discrete sizes of ions are present in considerable quantity at each value of the humidity. In addition it is shown that high mobility ions are present in small quantities; for example, at vapour pressure 0·87 mm., ions of mobility 12 cm./sec. constitute about 0·1 per cent of the total ionisation.

PARIS.

Academy of Sciences, Oct. 27.—The president announced the deaths of Pierre Termier and Paul Appell.—**Maurice de Broglie**: A possible conception of nuclear phenomena. **E. Bataillon** and **Tchou Su**: Abortion of gametogenesis in hybrids of *Molge marmorata* and *M. cristata*, two years old. **A. Buhl**: Wave geometry. Explicit developments. **V. Romanovsky**: The continued doubly connected chains of Markoff.—**Marcel Brelot**: A generalised problem of Dirichlet. **V. G. Siadbey**: The motion of large meteors. An analysis of a collection of data recently published by Hoffmeister. For large meteorites the average height of appearance (545 cases) was 131·9 km. and of extinction (553 cases) 53·5 km. Classifying in three classes, large meteors, detonating meteors, and meteorites, the geocentric velocities were respectively 42·5, 38·8, and 25·7 km. per second. **Henri Mineur**: The explanation of some anomalies presented by the proper motions of the stars. **Lyot**: The polarisation of Mercury compared with that of the moon; results obtained at the Pic-du-Midi in 1930. The clearness of the sky at the Pic-du-Midi enabled 26 observations to be taken under excellent conditions, the results of which are given graphically.—**Louis Kahn**: The methods of navigation employed by Costes and Bellonte. The method proposed by the author in earlier communications was used with success by Costes and Bellonte in their flight from Paris to New York. **A. Dauvillier**: The application of the diffraction of electrons to the study of organic substances. The structure of cellulose. Diffraction diagrams of organic substances can be obtained provided that extremely thin films, with a thickness of the order of 100 A., can be prepared. Diagrams are given for films of nitrocellulose: these are entirely different from those given by the X-rays and are not due to the crystalline network.—**Mlle. Foret**: Calcium chloro-, bromo-, and iodoaluminate. **H. Muraour**: The influence of radiation in the combustion of (explosive) colloidal powders in closed vessels. In a previous communication, as an explanation of the observed diminution in the area of the pressure-time curve, it was suggested that energy was contributed under the influence of the calorific radiation of the gas: further experiments now described prove that this hypothesis is insufficient to explain the experimental results.—**Justin Dupont** and **Jean Jacques Guerlain**: The dry distillation of Tolu balsam. This distillation gives rise to notable quantities of the monomethyl esters of pyrocatechol and its homologues, identical with those extracted by Béhal and Choay from wood tar creosote. **Georges Mignonac** and **Charles Hoffmann**: The ketene-imines and the tautomerism of the nitriles.—**St. Pavlovitch**: The metallographic study of some metallic minerals of Yugo-Slavia.—**Jacques Bourcart**: The stratigraphy of the Atlantic zone of the Spanish Protectorate in Morocco.—**L. Margaillan**: The vitamins and refining olive oils. Comparative curves of growth of rats are given, the diet being the same except that unrefined olive oil was added in one set and refined olive oil in the other. Contrary to the view generally held, olive oil contains vitamins, but these are reduced or eliminated by the process of refining. **E. Chemin**: The action of ultra-violet radiations on the spores and germination of the Florideæ. Arrest of development and cell alteration is always produced by the action of ultra-violet light.—**H. Colin** and **E. Bougy**: The characters of some hybrids of beetroot.—**Mme. L. Randoin** and **R. Lecoq**: The possibility of producing experimental rickets in the guinea-pig. Although very sensitive to a deficiency of the antiscorbutic vitamin, the guinea-pig does not appear to react to a deficiency of the antirachitic vitamin and presents no true rickety lesions.—**Aversenq, Jaloustre**, and **Maurin**: The neutralisation of the toxic power of various poisons by thorium-X. Either by its radioactivity or by its metallic ions, thorium X is capable of exercising in the animal or plant a certain amount of protective action against various poisons (sparteine, picrotoxin, potassium cyanide). The mechanism of this neutralisation is doubtful. **Fontaine**: Modifications of the internal medium of river fishes in the course of reproduction.—**S. Metalnikov, B. Hergula**, and **Miss Strail**: The utilisation of micro-organisms in the fight against *Pyralis* of maize. An account of field experiments carried out at Zagreb, with emulsions of cultures of micro-organisms isolated from dead or dying insects. The results were satisfactory.

LENINGRAD.

Academy of Sciences, *Comptes rendus*, No. 13, 1930.—**I. Kurbatov** and **V. Kargin**: Chemical composition and properties of the Crimean keffekilite.—**G. Frederiks**: The Palaeozoic deposits in the Urals. During the whole of the Palaeozoic period up to the end of the Carboniferous, only vertical movements occurred in the area of the Uralian geosynclinal. In the early Permian the first phase of the vertical folding occurred, while the second coincided with the end of the Chussov period.—**B. Kupletskij**: A contribution to the mineralogy of the Khibin tundras. Descriptions of a number of minerals. **B. Gavrusevich**: A new find of palygorskite in the Ukraine. **G. Laemmlein**: Corrosion and regeneration of quartz-porphyrites. **A. Saukov**: Antimony and molybdenum deposits near Novotroitzk, on the River Unda, Transbaikalia.

Comptes rendus, No. 14, 1930.—**N. Zelinjski**: Chemical nature of the Petchora bitumen.—**B. Galerkin**: A contribution to the investigations of tensions and deformations in an elastic isotropic body.—**V. Barovskij**: A description of two new species of the genus *Dictyoptera* Latr. (Coleoptera, Lycidæ) from eastern Asia. *D. motschulskii* and *D. miranda*, spp. nn., from the South Ussuri region.—**L. Jakubova** and **E. Malm**: The phenomena of the temporary anærobiosis in some representatives of the Black Sea benthos. Experiments in the aquarium showed that the majority of benthonic animals, particularly the less mobile or sedentary animals, can live for a long time (more than a month) at very low concentrations of oxygen—for example, at 0·2-0·4 c.c. per litre at 12° C. **N. Kuznecov-Ugamskij**: A contribution to the study of the factors of the evolution of faunistic groups. The evolution of faunas is due not only to the evolution of the environmental conditions, but also mainly to the interaction of different component elements of the fauna.—**N. Filipjev**: Lepidopterological notes (7). A new genus of Tortricidæ from the mountains of the Ussuri region. *Eurydoxa advena*, gen. and sp. n.—**V. Rylov**: A preliminary communication on the plankton of Lake Kardyvatch, north-west Caucasus.

Official Publications Received.

BRITISH.

Commonwealth of Australia: Council for Scientific and Industrial Research. Bulletin No. 45: A Soil Survey of the Woorinen Settlement, Swan Hill Irrigation District, Victoria. By J. K. Taylor and F. Penman. Pp. 41+4 plates. (Melbourne: H. J. Green.)

Ministry of Agriculture and Fisheries. Report on the Work of the Research and Education Division for the Year 1928–29. Pp. 100. (London: H.M. Stationery Office.) 1s. 6d. net.

Government of India: Meteorological Department. Magnetic, Meteorological and Seismographic Observations made at the Government Observatories, Bombay and Alibag, in the Year 1926, under the direction of Dr. B. N. Banerji and Dr. K. R. Ramanathan. Pp. iv+135+5 plates. (Calcutta: Government of India Central Publication Branch.) 10.12 rupees; 17s. 6d.

Proceedings of the Geologists' Association. Edited by A. K. Wells. Vol. 41, Part 3, 21st October. Pp. 221-362+plates 15-28. (London: Edward Stanford, Ltd.) 5s.

The Gardens Bulletin, Straits Settlements. Vol. 6, Part 3: The Medical Book of Malayan Medicine. Translated by Inche' Ismail, Munshi, possibly in Penang, circa 1886. Now edited with Medical Notes by J. D. Gimlette, and Determinations of the Drugs by I. H. Burkill. Pp. 323-474. (Singapore: Botanic Gardens.) 2.50 dollars.

British Cast Iron Research Association. Ninth Annual Report for the Year ending June 30th, 1930. Pp. 27. (Birmingham.)

The Book Window: a Guide to Book Buying and Book Reading. Vol. 2, No. 5, Christmas Number. Pp. 149-188. (London: W. H. Smith and Son, Ltd.) 3d.

Diary of Societies.

FRIDAY, NOVEMBER 28.

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (Scottish District) (at County Buildings, Paisley), at 2.—T. Somers: The Sixth International Road Congress at Washington, D.C.

GENETICAL SOCIETY (at Linnean Society), at 3.—A. E. Gairdner and Dr. C. D. Darlington: The Theory of Ring-formation exemplified by *Campanula persicifolia*.—J. Philp: An Explanation of the Inheritance of Double Flowers in *Matthiola incana R.Br.* based on Cytological Evidence.—At 3.45.—Prof. A. H. R. Buller: Sexual Phenomena in the Higher Fungi.—C. Diver: Studies in the Genetics of the Common Garden Snail, *Helix aspersa*.—A. A. Moffett: Cytology of Pomoideae.

ROYAL SOCIETY OF MEDICINE (Children Section), at 5.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle-upon-Tyne), at 6.—W. S. Hinde: The Ocean-going Tramp Steamer from the Owner's Point of View.

INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section), at 6.15.—Lt.-Col. H. E. O'Brien: Electric Traction (Students' Lecture).

INSTITUTION OF STRUCTURAL ENGINEERS (at Chamber of Commerce, Birmingham), at 6.30.—W. T. Benslyn and S. Willis: Steelwork in Cinema Construction.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemical Section), at 7.—R. Humphries and others: Discussion on Colorimetration in Textiles.

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—E. Batten and others: Discussion on Export Trade Emancipation.

SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section) (jointly with Society of Dyers and Colourists and Institute of Chemistry) (at 235 Buchanan Street, Glasgow), at 7.15.—F. W. Lake: Dyeing and Cleaning: Some Problems of the Industry.

MANCHESTER ASSOCIATION OF ENGINEERS (at Engineers' Club, Manchester), at 7.15.—F. W. Rowe: The Selection and Treatment of Materials for Gears.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—G. H. Willett: Photography applied to Science.

ROYAL SOCIETY OF MEDICINE (Epidemiology Section), at 8.—Dr. J. M. Hamill: Food as a Preventive of Disease.

INSTITUTION OF CHEMICAL ENGINEERS.—S. Mayne: The Sources of Published Technical Data and how they should be used.

SATURDAY, NOVEMBER 29.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—H. Plunket Greene: Verse in Song.

MONDAY, DECEMBER 1.

ROYAL SOCIETY, at 4.—Anniversary Meeting.

ROYAL SOCIETY OF EDINBURGH, at 4.30.—Dr. G. Bond: The Stem-endodermis in the Genus *Piper*.—A. Graham: On the Morphology, Feeding Mechanisms, and Digestion of *Ensis siliqua*.—Dr. L. Mirskaia and Prof. F. A. E. Crew: On the Pregnancy Rate in the Lactating Mouse, and the Effect of Suckling on the Duration of Pregnancy.—Dr. B. P. Wiesner: Further Observations on the Mechanism of the Diphasic Sex Cycle.

VICTORIA INSTITUTE (at Central Hall, Westminster), at 4.30.—Sir Ambrose Fleming: Adaptation in Nature as Evidence of Purposive Thought.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Meeting.

SOCIETY OF ENGINEERS (at Geological Society), at 6.—W. R. Baldwin-Wiseman: Some Ground Aspects of Aviation.

BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (Annual General Meeting) (at London Day Training College), at 6.—Miss S. Clement Brown: Some Case Studies of Delinquent Girls described as Leaders (From Social Study made in the County of Los Angeles, California.)

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—J. R. Leathart: Modern Cinema Design.
ROYAL SOCIETY OF ARTS, at 8.—Prof. C. R. Darling: Modern Domestic Scientific Appliances (Cantor Lectures) (2).
SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8.—J. H. Coste: Analytical Chemistry, its Past, History and Future Development (Lecture)
ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Rev. J. W. Hubbard: The Isoko Country, Southern Nigeria.

TUESDAY, DECEMBER 2.

IMPERIAL COLLEGE CHEMICAL SOCIETY (in Main Chemistry Lecture Theatre, Royal College of Science), at 5.10.—Prof. J. F. Spencer: Magneto Chemistry.
ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Prof. E. A. Milne: Stellar Structure and the Origin of Stellar Energy (1)
INSTITUTION OF CIVIL ENGINEERS, at 6
SOCIETY OF CHEMICAL INDUSTRY (Birmingham and Midland Section) (at Chamber of Commerce, Birmingham), at 6.45.—Dr. R. S. Morrell: The Oxidation Products of Drying Oils.
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—P. B. Bannatt: Ten Thousand Miles with Two Babies
INSTITUTE OF METALS (Scottish Local Section) (jointly with Institution of Engineers and Shipbuilders in Scotland) (at 39 Elmbank Crescent, Glasgow), at 7.30.—W. Lambert: Non-ferrous Alloys used by Engineers.
INSTITUTION OF AUTOMOBILE ENGINEERS (at Royal Society of Arts), at 7.45.—J. Bradley and S. A. Wood: Some Experiments on the Factors affecting the Motion of a Four-wheeled Vehicle when some of its Wheels are locked.—J. Bradley and R. F. Allen: Factors affecting the Behaviour of Rubber Tyred Wheels on Road Surfaces.
ROYAL SOCIETY OF MEDICINE (Orthopædics Section), at 8.30.—Dr. L. Bohler: The Treatment of Fractures of the Upper Extremity.

WEDNESDAY, DECEMBER 3.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Dr. P. Tesch: The Riss Glaciation in the South-Eastern Parts of England.—H. Dewey: The Palæolithic Deposits of the Lower Thames Valley.
INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—T. Walmsley: Beam Arrays and Transmission Lines.
INSTITUTION OF HEATING AND VENTILATING ENGINEERS (at 20 Hart Street, W.C.1), at 7.—E. G. Phillips: The Cost of Operating Industrial and Private Electric Generating Sets compared with Public Supply.
NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (at Newcastle-upon-Tyne), at 7.15.—J. C. Dixon: Wharf Cranes for the Handling of Cargo.
ROYAL SOCIETY OF ARTS, at 8.—S. Perks: The Building of the Mansion House.
SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society), at 8.—G. Middleton: A Storage and Delivery Apparatus for Antimony Chloride Solution and other Corrosive Reagents.—G. Middleton and F. C. Hymas: Tests for Impurities in Ether. Parts II. and III.—N. Evers: The Determination of Small Quantities of Calcium in Magnesium Salts.—Dr. F. K. Rose: A New Method for the Detection of Nitro-Group in Organic Compounds.
ROYAL SOCIETY OF MEDICINE (Surgery Section), at 8.30.—Discussion on Surgery in Diabetes. Openers: Prof. G. E. Gask, Dr. G. Graham, and Dr. Lawrence.

THURSDAY, DECEMBER 4.

LINNEAN SOCIETY OF LONDON, at 5.—Dr. J. McLuckie: On a Natural *Grevillea* Hybrid.—B. Storrow: Some Fluctuations in Zoological Populations during the Nineteenth Century.
ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Sir John Russell: The Agricultural Development of the Empire (1): Reclaiming the Wastes.
CHILD STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Dr. C. W. Kimmins: The Changes in the Child's Attitude to Life during the School Period.
INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—S. G. Brown: Loud-Speakers since their Conception with Gramophone Pick-ups and Wireless Recording Apparatus (Lecture)
ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6.30.—H. Glauert: The Four-Foot Wind Tunnel.
SOCIETY OF CHEMICAL INDUSTRY (Nottingham Section) (at University College, Nottingham), at 7.30.—E. Potter: Patents.
CHEMICAL SOCIETY, at 8.

FRIDAY, DECEMBER 5.

ROYAL SOCIETY OF MEDICINE (Otology Section), at 10.30 A.M.—Dr. G. Riddoch, Dr. A. B. Rosher, and others: Discussion on Intracranial Complications of Otitic Origin: Neurological and Pathological Investigation.
ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 5.
PHYSICAL SOCIETY (at Imperial College of Science), at 5.—Dr. L. C. Martin: The Theory of the Microscope.—M. Fahmy: A Point of Analogy between the Equations of the Quantum Theory and Maxwell's Equations.—B. K. Johnson: Sources of Illumination for Ultra-violet Microscopy.—W. A. Wood: The Influence of the Orientation of the Cathode on that of an Electro-Deposited Layer.—Demonstration by Prof. G. B. Bryan of some Stroboscopic Effects.
SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (in Muspratt Lecture Theatre, Liverpool University), at 6.—U. R. Evans: The Protection of Metals by Painting.
INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Prof. W. E. S. Turner: Machinery and Methods of Manufacture of Sheet Glass.
SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (at Engineers' Club, Manchester), at 7.—Dr. T. Callan: The Estimation of Minute Traces of Copper.—Dr. F. C. Wood: (*a*) The Reaction of Formaldehyde Derivatives with Cellulose; (*b*) The Formation of Mono-cellulose Methylene Ether; (*c*) The Action of Grignard Reagent on Cellulose.—C. M. Whittaker: Some Notes on Viscose Dyeing.—J. M. Preston: A Skin Effect on Viscose Rayon.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group), at 7.—Informal Meeting.
INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section) at 7.—O. Howarth: The Metering of Three-Phase Supplies.
JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7.30.—R. L. Mayston: Oil Burning for Domestic Central Heating.
GEOLOGISTS' ASSOCIATION (in Architectural Theatre, University College) at 7.30.—A Journey through South and West Africa, with special reference to Igneous Phenomena (Lecture).
LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemistry Section) (jointly with Leicester Association of Engineers) (at College of Technology, Leicester), at 7.30.—G. F. O'Riordan: Recent Developments in Chemical Engineering.

SATURDAY, DECEMBER 6.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir E. Denison Ross: Persia and the Persians (1): The Country and its History.

PUBLIC LECTURES.

FRIDAY, NOVEMBER 28.

ROYAL SOCIETY OF ARTS, at 5.30.—Sir Robert Philip: The Outlook on Tuberculosis: Changing Orientation (Malcolm Morris Memorial Lecture)

SATURDAY, NOVEMBER 29.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss I. D. Thornley: Some Mediæval Beasts, Real and Otherwise.

MONDAY, DECEMBER 1.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—F. W. Twort: Diseases of Bacteria. (Succeeding Lectures on Dec. 3, 5, 8, and 10.)
UNIVERSITY OF LEEDS, at 5.15.—Prof. F. O. Bower: The Morphology of the Leaf.

TUESDAY, DECEMBER 2.

KING'S COLLEGE, LONDON, at 11 A.M.—S. P. Turin: The Economic Geography of U.S.S.R.: Industry, Export and Import.—At 5.30.—Miss Hilda D. Oakeley: The Approach to Reality: Through Art.

WEDNESDAY, DECEMBER 3.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Prof. D. B. Blacklock: The Prevention of Disorders and Disease in Tropical Countries.
BELFAST MUSEUM AND ART GALLERY, at 8.—Dr. A. Mahr: A Bygone Craft: Making an Old Style Coracle on the River Boyne.

THURSDAY, DECEMBER 4.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Dr. F. J. McCann: Medical Arguments against Contraception.

SATURDAY, DECEMBER 6.

MATHEMATICAL ASSOCIATION (at Bedford College), at 3.—Dr. Cyril Norwood: The Value of Exactness (Presidential Address).
HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: Prehistoric Man in Minorca.

CONGRESSES AND EXHIBITION.

DECEMBER 3, 4, AND 5.

BRITISH INSTITUTE OF RADIOLOGY (at Central Hall, Westminster).
Wednesday, Dec. 3, at 2.30.—Sir Humphry Rolleston, Bart.: Official Opening.
At 3.30.—Major C. E. S. Phillips: Presidential Address.
Thursday, Dec. 4, 10.30 to 12.30.—F. D. Owen King: The Multix Tube; a Self-Protected Tube for Therapy and Diagnosis with Twin Focus.
W. E. Schall: Limitations of the Single Valve Unit.
A. C. Gunstone and E. J. W. Watkinson: (*a*) The Milli-Ampere Second Relay; (*b*) A New Type of Control for X-Ray Apparatus.
At 5.—Prof. G. P. Thomson: Some Recent Experiments on Cathode Rays (Mackenzie Davidson Memorial Lecture).
Friday, Dec. 5, 10.30 to 12.30.—Dr. H. A. Harris: The Growth of Bone as illustrated by Radiography.
Dr. D. Hunter: Changes in the Bones in Hyperparathyroidism and Hyperthyroidism.
At 4.30.—Dr. A. E. Barclay: The Danger of Specialisation (Silvanus Thompson Memorial Lecture).

DECEMBER 4 AND 5.

INSTITUTION OF CHEMICAL ENGINEERS (at Chemical Society).—The Utilisation of Trade Wastes.
Thursday, Dec. 4, at 10.30 A.M.—J. B. C. Kershaw: Industrial Wastes.
A. T. King: The Treatment of Suint Liquors from Wool Scouring.
B. A. Smith: The Treatment and Disposal of Wool washing Effluent.
At 2.30.—R. J. Marx: Whitewater in Paper and Pulp Mills and its Utilisation.
M. Schofield: The Distillation of Wood Waste and the Utilisation of the Products.
R. W. Griffith: The Utilisation of Industrial By-Products, with Special Reference to the Pulp Industry of the United States of America.
Friday, Dec. 5, at 10.30 A.M.—Dr. D. J. Lloyd: The Problem of Tannery Waste.
O. Wans: The Use of Wood Waste for Heating and Generation of Power.
At 2.30.—E. B. Busenburg: The Utilisation of Waste Rubber.
Prof. J. W. Hinchley: The Recovery of Metal from Waste Materials.

SATURDAY, DECEMBER 6, 1930.

No. 3188, Vol. 126]

The Neglect of Scientific Method.

THE address by Sir William Pope, at Goldsmiths' Hall on Nov. 13, the sixth of the annual Norman Lockyer lectures instituted by the British Science Guild,* must be accounted one of the most weighty of recent scientific pronouncements, as well as most opportune, in its bearing upon two subjects of special interest at the moment —the extension of the Dyestuffs Act and the school-leaving age. It is to be hoped that, without delay, the printed lecture may, in some way, be brought under the notice of every headmaster and of every member of Parliament: as the girls to-day are even more victimised than are the boys at school and college by the imposition of a burden of inconsequent, undigested learning, headmistresses might also be induced to understand the implications of the address.

Sir William Pope does well to lay stress upon the fact, that modern man is in no appreciable degree the intellectual superior of his forerunners in the far fringe of historic time: he differs from them only in having other weapons. As he truly says, the forms of intellectual expression we recognise as the arts and literature, even moral philosophy, were worked out thousands of years ago, to the utmost limit of the capacity of the human mind. No convulsive revolutionary change could affect our outlook, our powers and our achievements, except the discovery and exercise of some unsuspected faculty of our intelligence. Such a faculty is now to be recognised as operating in the background in the modern development of the natural sciences *by experimental study*, wherein we may see a most wonderful fulfilment of Shelley's far-seeing foresight:

> A mighty Power, which is as darkness,
> Is risen out of earth and from the sky
> Is showered and, from within the air,
> Bursts, like eclipse which had been gathered up,
> Into the pores of sunlight.

The Power is no longer "as darkness" but a sublime light. The intensive work which has been done in science, largely during the last fifty years, has launched us, says Sir William Pope, well beyond the shore of a new era in the world's history, an era which may be described as the scientific age. Unfortunately, the process is in no way understood even by the superior politician, let alone the public. The words science and scientific as yet have no properly defined meaning in the public mind; even in scientific journals they

* "Science and Modern Industry." By Sir William J. Pope. Pp. 16. (London: British Science Guild, 1930.) 1s.

are often inconsistently used and rarely with forethought. We have no right to confine the word science to any particular branch of knowledge; moreover, all exact and logical users of knowledge and experience are entitled to be spoken of as scientific. The modern advance, in all fields, is due to our considered application of knowledge and our constant verification of whatever conclusion we may draw: only the verified is science. Much that so passes at the moment is mere speculation. In days gone by, conclusions were based upon first principles, without verification.

The great Helmholtz tells us, in his biography, how the philosophers, in his early days, regarded the introduction of experimental verification as unnecessary; in fact, as almost an insult to their dignity. Our use of the Latin word science, in place of knowledge, as if it meant something different and peculiar, is at the root of the difficulty: as a people, we cannot suffer Latin; much as we use it in our spoken language, we seem rarely to grasp the full meaning of Latin words. Until we study English, we never shall - unfortunately, this subject is still all but unknown in the schools, whatever stopped the way in the past, 'science' now crowds it out! Much of Sir William Pope's address is devoted to a criticism of the general literary ignorance of young people coming up to the university from the schools. He also complains bitterly of the neglect of modern languages. Being himself gifted with most remarkable linguistic ability, no one has greater right to speak upon the subject.

That a leading professor at a leading university should so speak out is a more than welcome sign that, at last, we are beginning to appreciate the danger of our position—that at last we see that the vicious circle in which youth is forced to revolve must in some way be broken and teaching made the free and considered practice of the greatest of all arts—an art nothing short of sacred. Research will soon be its own executioner, if we do not bring under effective consideration the methods of training used in school and university leading up to such work. What is now done is mainly by way of compensating for the absence of a proper educational foundation upon which a scientific superstructure may be built. The present situation is farcical. Trained at school and, say at Oxford, up to the end of his third year, to remain ignorant of method, suddenly the student is called upon to study 'the methods of research'—usually by working out an additional example after a well-known rule: in the main, he merely raises his value as an artificer. The art of logical inquiry and study—scientific method should be inculcated from the cradle upwards: it is not to be learnt from the conventional 'research'.

This is really the meaning to be read into Sir William's address: and Brutus is an honourable man. He is a man who has shown supreme general business ability, having recently passed through the high City office of Prime Warden of the Goldsmiths' Company with great distinction. He is therefore a double first. His complaint is that most of the men in business and the politicians—I suppose he would say without exception—have no scientific training: they are empiricists, members of a class who have done in late years and are doing to-day, with alarming efficiency, everything possible to wreck our national fortune. It is in the hands of such men that the fate of our dyestuff industry rests: theirs not to reason why, the decision is likely to be one taken without any intrusion of scientific method: the more as the industry is pre-eminently scientific, in origin and development.

In fact, our era is not yet to be spoken of as 'scientific', whatever the Norman Lockyer lecturer may assert. So few among us have any use for scientific method that the vast mass perish for want of such knowledge. Knowledge we have—a vast knowledge: only the knowledge how to use knowledge profitably is wanting among us. Our great present need is to appreciate the depth of our ignorance, especially in education.

Sir William Pope in and by his address sounds the trumpet call for action in the universities: it behoves the few who are alive to our educational peril to be up and doing, in remedy of his indictment. The headmasters will not move—they have not the courage nor any leader: the schools examining bodies will be opposed to all action; the public always leaves school to 'mother'. A colossal burden of responsibility rests upon the few at the universities who are aware of the straits into which education has drifted, through entire lack of scientific control, left as it has been in bureaucratic, unpractical hands. The universities, whatever may be said, *are* the prime source of all evil as well as of the little good in the prevailing chaos of teaching: they must cure themselves, in the first instance. Educationally they are unco-ordinated. We *must* exorcise the competitive lust that is within us, to the extent that we cease from treating education as if it were a branch of sport and our schools racing stables. In some way, we *must* take the money out of the examination purse and put 'morality' into its

place. In some way, education must be made real and of general avail—not the entirely fortuitous, inhibitory process it now too often is.

So little scientific is our era, that the chief use we have made of our great knowledge has been to squander natural resources in a blind and selfish pursuit of wealth. Industry, to-day, is entirely inconsiderate of the future. We cannot continue at present rates. The solution of the nitrogen problem by Crookes has brought us nearer to destitution rather than saved us, as the blind worshippers of mechanical success assert it has, by hastening the rate of depletion of irreplaceable phosphatic stores. We can clearly foresee in phosphorus the limiting essential factor to the world's progress:

Ohne Phosphor kein gemixte Pickles

stands written upon the wall. If we have any regard for the future, without loss of time we must learn to submit ourselves to scientific control. Unless we overcome the demagogue, there will be no health in us.

Sir Norman Lockyer, I am sure, would indeed have been more than satisfied to hear an address delivered in his memory such as that just given under the auspices of the Guild he founded. Never has the existence of the Guild been so fully justified: still, we cannot rest content with talk, however eloquent. The red flag of revolt must now go forward; the time for mercy to the incompetent is over.

HENRY E. ARMSTRONG

Persia and the Persians.

A History of Persia. By Brig.-General Sir Percy Sykes. Third edition with Supplementary Essays. Vol. 1. Pp. xxxix + 563 + 15 plates. Vol. 2. Pp. xx + 616 + 16 plates. (London: Macmillan and Co., Ltd., 1930.) 2 vols., 42*s.* net.

LORD CURZON'S classic work on Persia, published in 1892, went out-of-print a few years later, and was never reprinted. Sir Percy Sykes made his debut in Persia in the following year, and but for interludes in South Africa and Turkestan was, until December 1918, on duty in that country as a consular official, representing His Majesty's Government and the Government of India. He has travelled very extensively, and to good purpose: he has written four other books on various aspects of life and manners in Persia, and is unquestionably the leading authority in Britain on the matters dealt with in the present work. That he should have found time, in the midst of his travels and official labours, to compile this history (the first edition was published in 1915) is a tribute to his versatility and to his pertinacious industry, for to write a standard historical work in a consulate in a remote provincial town on the borders of Central Asia is a task at which few men would persevere. That a third edition should be called for within fifteen years is a tribute to the widespread interest displayed by the English-speaking world in Oriental history.

"Official duty", said Lord Rosebery in 1898, "is only a very small part of public duty, and public work is by no means incompatible with other professions and other callings." The great historians of the East in the English language have with few exceptions been soldiers and administrators, who have been at pains to follow the precept of Habakkuk and to read as they ran. Sir Percy Sykes is the worthy successor in the field of Middle Eastern history of such men as Malcolm, Morier, Rawlinson, and Curzon.

The history of Persia is of unique importance to the student of past times, for, thanks to the discoveries of the last century, it constitutes a longer and more continuous record than that of any other country or nation. A few salient facts, as disclosed by the work under review, of special interest to readers of NATURE, relating to ethnography and to the Persian people and their contributions to the progress of the human race, are worth mentioning.

In no eastern country is 'national' sentiment stronger; yet in no country has there been a greater admixture of extraneous elements. Persia has in the last two thousand years been overrun repeatedly by foreign invaders—by Arabs in the seventh century, by Mongols in the thirteenth, by Turks in the seventeenth, by Afghans in the tenth, and Russians in the nineteenth; at least six different racial strains are apparent amongst the population to-day, and as many languages are currently spoken, namely, Arabic in the south-west, Baluch (Brahui) in the south-east, Kurdish in the west, Turkish almost everywhere except in the centre, to which must be added the Tajik of the Caspian provinces, and Luri—which has strong affinities to the ancient Pehlevi tongue—in the south-west. Yet the Persian kingdom has had a continuous and unbroken existence since the dawn of history, and has extended at different times to Cairo and Delhi, to Samarkand and to the Hijaz.

The extensive conquests made by the armies of successive rulers entailed further great admixture of blood, for the Persian soldiery were wont to

bring back strange wives, and slaves not a few. Yet the Persian racial traits were far less impaired than were, for example, those of the Greeks, amongst whom, as W. G. Clarke points out ("Peloponnesus", p. 328), Miltiades, Thucydides, and Demosthenes were notoriously of mixed race, and contemporary arts and crafts, which reached their highest development in the ancient world within the confines of Persia, as the forthcoming International Exhibition of Persian Art in Burlington House will show, retained all the characteristics of the soil that gave them birth.

The Persian plateau, alternately frozen by bitter winds and scorched by a pitiless sun, is one of the most ancient land surfaces of the Old World: it may yet prove to have been one of the cradles of the human race, and it has incontestably been shown to be one of the most ancient of civilisations. Its fauna and flora have little affinity with those of India, but are closely allied to those of Europe; some indeed hold that it is to Persia that we owe the prototypes of the vine and the genus *Prunus*, and several other trees now widely spread over the world.

Arduous but not intolerable climatic conditions, and the predominance over considerable areas of limestone formations, have probably played on the Persian plateau an important part in forming and fixing types of human beings, animals, and plants alike, but this interesting subject has as yet not, so far as the reviewer is aware, formed the subject of systematic inquiry or informed speculation.

Persia may well have been the home of astronomy, ere Nineveh was built, as it was of the most philosophical of ancient beliefs which Zoroaster reduced to a system: it gave birth to kings such as Cyrus and Darius, to poets such as Firdausi, Hafiz, and Sadi, and to doctors such as Avicenna. Yet Persia, in more modern times, was the first of eastern nations to associate itself with international agreements such as those relating to posts and telegraphs; it was the first eastern power to take an active and useful part in the deliberations of the League of Nations, the first to take European advisers into the service of the State, and the first, also, to dispense with them. These matters, and much else, are dealt with fully in this closely packed and well-written work, which, up to and including Chapter lxxxiv., will for this generation be the standard work on the history of the country, to the study of which for forty years Sir Percy Sykes has devoted his talents.

A. T. W.

Bacteriology and Medicine.

Medical Research Council. A System of Bacteriology in relation to Medicine. Vol. 5. By W. Bulloch, S. L. Cummins, F. W. Eurich, J. T. Duncan, A. Fleming, S. R. Gloyne, W. Fletcher, A. Stanley Griffith, R. T. Hewlett, J. C. G. Ledingham, J. A. W. McCluskie, A. D. McEwen, J. McIntosh, F. C. Minett, E. Muir, C. C. Okell, R. St. John-Brooks, A. W. Stableforth, W. H. Tytler, L. E. H. Whitby. Pp. 506. (London: H.M. Stationery Office, 1930.) 21s. net.

THIS volume deals with glanders, melioidosis, diphtheria, tuberculosis, Johne's disease, leprosy, Malta fever, anthrax, and a few other less important diseases.

The short historical notes which appear at the beginning of several of the chapters are written by Prof. Bulloch, and this at once guarantees their accuracy and their interest. In the chapter on glanders he pays very just tribute to the work of Löffler. He writes: "Four years after Löffler's first paper with Schutz he published another (Löffler, 1886), in which he gave a masterly account of the bacteriology of glanders and practically without an error. Little has really been added to the pure bacteriology of glanders since Löffler gave us his account." An examination of the whole chapter, written by F. C. Minett, amply confirms this statement. There is really nothing new, nothing which has not been written over and over again in various text-books. The chapter is an account, and really a very good account, of the facts we have known for a very long time about this disease.

The short chapter on melioidosis caused by *B. Whitmori* is well written, and as it comes from the pen of William Fletcher it naturally emphasises many facts brought out by his own work. Bacteriologists generally, but particularly those working abroad, will welcome this chapter. It is a very valuable contribution.

Chapter iii., on *C. diphtheria* and diphtheroid organisms, is by Dr. Hewlett. It is stated in the introduction by Dr. Hewlett that in this article he has in a large measure epitomised the work published in 1923 by the Medical Research Council in its monograph on "Diphtheria". It is a very good epitome, and gives in a very readable form all the main facts which are of value in connexion with these bacteria. In regard to the laboratory diagnosis, there are some very pertinent remarks on p. 101—remarks which are very much needed in these days when the laboratory is so often regarded

as a mere diagnostic institution. As Hewlett says, "The only justification for awaiting a laboratory report is when the presumption is, on the whole, against diphtheria". The portion of this chapter dealing with the diphtheroid organisms and the avirulent strains of *C. diphtheriæ* gives a very accurate account of the present position of these organisms in relation to diphtheria.

Chapter iv., on tuberculosis, is, in our opinion, easily the best chapter in this volume. Dr. Griffith and those who have been associated with him in the production of this chapter are to be heartily congratulated. Naturally, the portions written by Dr. Stanley Griffith stand out as the work of a man who has devoted the greater part of his medical life to a careful study of the pathology and bacteriology of tuberculosis. It is marked by very many original observations. The author is not merely satisfied to give the opinions of other workers, but his discussion of their observations and their deductions brand this chapter as the work of a man not merely of keen observation but also of real critical power. We feel sure it will stand out as one of the very best summaries, and true critical summaries, on tuberculosis which have been published.

S. R. Gloyne deals with the distribution of tubercle bacilli and their resistance to destruction, and W. H. Tytler with allergy and immunity. The former part is interesting from the public health point of view, but somewhat indefinite; the latter is a very useful and valuable contribution. It gives all the main facts as to immunisation by living and dead bacteria and bacterial products. Naturally, the author does not commit himself to definite conclusions, but he gives an accurate report on experimental results and discusses them with great fairness. The treatment by tuberculin is dealt with by Dr. Fleming, the preparation and standardisation of tuberculin by Dr. Okell, chemotherapy in tuberculosis by Prof. Cumming, and the laboratory diagnosis by Prof. McIntosh and Dr. Whitby.

There is a short but interesting chapter on "Tuberculosis in Cold-Blooded Animals" by Dr. Stanley Griffith.

Johne's disease is discussed in Chapter vi. by Mr. A. W. Stableforth. This is a record of all the main facts in relation to the bacteriology and morbid anatomy of this disease, well put together but lacking in any originality or critical discussion.

Leprosy is dealt with in Chapter vii. by Dr. Ernest Muir. One expects from a writer who has had a wide practical experience with leprosy, and has done a great deal of experimental work both in relation to its bacteriology and its treatment, a very full account of the pathological and bacteriological aspects of this disease. The author certainly does not fail us. His facts are well marshalled, and though he gives the views of almost all the workers on the subject, he is careful to draw conclusions only from facts which have been fully established. Thus, reviewing the work which has been done on the cultivation *in vitro* of *B. lepræ*, he does not criticise adversely the statements of the various experimenters, but he gives careful notes for guidance, notes which, had they been followed, would have prevented some of the writers from drawing their erroneous conclusions.

Chapter viii., on the non-pathogenic acid-fast bacilli, by R. St. John Brooks, is useful as an addendum to the chapters on tuberculosis, Johne's disease, and leprosy.

Dr. J. T. Duncan and L. E. H. Whitby contribute Chapter ix., on the Brucella Group. On this group a considerable amount of experimental work has recently been done, and the writers have done full justice to it. To those who wish a very good account not only of the pathology and bacteriology but of the chemotherapy, prevention, etc., of the diseases due especially to the *B. melitensis* and paramelitensis, we commend this chapter. The relation of *B. abortus* in the milk of cows to undulant fever is dealt with and all the relevant facts noted. This is a very useful article to the bacteriologist and the public health officer.

Chapter x., on *B. anthracis*, is by Dr. F. W. Eurich and R. T. Hewlett. This is simply a statement of known facts. The article does not call for special comment. It is a useful summary, dealing with the bacteriology, the pathology, and serum therapy of the disease. In the portion dealing with practical diagnosis, the estimation of the opsonic index, it is said, may prove useful in the hands of one who has acquired the necessary skill. One wonders how many times the opsonic index has been found useful in the diagnosis of anthrax.

In Chapter xi., R. St. John-Brooks writes on the non-pathogenic spore-bearing aerobic bacteria. This naturally follows the chapter on anthrax. It is a compilation of views of various authors and leaves the reader rather confused than otherwise. In the classification, the writer claims to follow Ford and his co-workers. It is difficult to see any reason why this classification was followed at all, if, as is the case, it was not followed completely. There is nothing in the chapter to indicate any reason for this. To take one example—the Cohærens-simplex

group; the writer gives three organisms, whereas Ford gives five. If the three were considered the only important ones and some mention made of them in the later text, one could have understood the omission, but they are not mentioned. If the whole classification had been omitted—for it serves no useful purpose in this article—the chapter would have been improved.

Chapter xii., on tularæmia, and Chapter xiii., on Bartonella and allied diseases, are useful additions which had necessarily to be included in some part of the series.

Throughout the volume the nomenclature is irregular, and we think it would have been wise either to adopt the recent American method throughout or not at all. Thus we find *Brucella melitensis*, *Corynebacterium diphtheriæ* alongside *Bacillus mallei* and *Bacillus tuberculosis*.

Taken on the whole, the volume is good, but scarcely up to the standard of the ones previously issued. With the exception of the chapters specially noted in the review, we do not think that by the issue of this volume any valuable addition has been made to bacteriological libraries.

J. M. BEATTIE.

German Work on Silicates.

Veröffentlichungen aus dem Kaiser Wilhelm-Institut für Silikatforschung in Berlin-Dahlem. Herausgegeben von Prof. Dr. Wilhelm Eitel. Band 3. Pp. 134. (Braunschweig: Friedr. Vieweg und Sohn A.-G., 1930.) 36 gold marks.

EDITED by Dr. W. Eitel, director of the Kaiser Wilhelm Institute for Silicate Research in Berlin, the third volume of publications issued from the Institute comprises a collection of twelve papers and reports, eight of which have previously appeared in various German technical journals during 1929. Among the contributors are W. M. Cohn, B. Lange, E. Kordes, and C. Gottfried, each of whom is concerned (alone or in conjunction with a fellow-worker) in two or more of the articles.

W. M. Cohn is responsible for two papers, the first being an illustrated account of a new self-registering apparatus for determining the thermal expansion of solid bodies. By the use of this contrivance, the expansion curves of solid rods can be obtained photographically up to temperatures beyond 800° C., so that even small effects, such as those representing transformation points, can be clearly perceived. Cohn's other paper relates to the expansion behaviour of new stoneware bodies, studied with the aid of the appliance described in his first paper. Results are cited indicating that a new stoneware body has been produced which possesses very low expansion values, the expansion being fairly regular. By altering the composition of the body, it is possible to produce various expansion values between those of silica glass and ordinary ceramic bodies.

B. Lange discusses the coloration and origin of gold ruby glass: with W. Heller the same author describes tellurium-platinum thermo-elements which permit very accurate determinations of low temperatures over small ranges (20° to 40°, 0° to 40°, and with certain conditions from −75° to +90°); a tellurium-bismuth thermo-element is also referred to. Lange and W. Cousins discuss the molecular condition of fused sulphur. Lange and H. Möhl discuss the application of sedimentation analysis (of Wiegner-Lorenz) and of depolarisation methods to ceramic analysis, citing experimental results obtained with various clays and kaolins.

E. Kordes contributes a somewhat lengthy paper on the lowering of vapour pressure in concentrated solutions of two volatile components; in collaboration with E. Klever, the results of calorimetric investigations on dehydrated kaolin are reported. Kordes and F. Raaz present a paper on boiling diagrams of binary high-boiling liquid mixtures (of mercury and cadmium, and of the chlorides of sodium and potassium, respectively), the measurements of vapour pressures or boiling points being carried out by the spiral method devised by O. Ruff.

C. Gottfried gives a short (second) paper on minerals of the Adamello group, dealing with hornblende from a special material found in the Val di Dois; jointly with E. Lubberger he contributes a short article on antimonite.

G. Trömel is the author of the remaining paper, in which silicates (or rather alumino-silicates) of the type of nepheline and anorthite are discussed at considerable length, including an account of results obtained from X-ray examinations and by the substitution of soda for lime (and vice versa) in such alumino-silicates, and also the results of substituting certain rare earth oxides for alumina in similar compositions. Some interesting deductions are drawn from the results obtained.

Fixed to the inside of the back cover as an appendix is a copy of the sixth part of the fifth year of *Schriften der Königsberger Gelehrten Gesellschaft*, consisting of a paper by W. Skaliks on some double combinations of alkaline carbonates with carbonates of alkaline earths.

While it may be admitted that several articles in the volume under consideration would scarcely

appeal to most readers of even scientific literature, others present features capable of useful application, and the whole volume constitutes an important record of high-class research. Such a miscellaneous assortment of papers does not provide an easy task for a reviewer, but it is hoped that sufficient indications have been given to enable readers interested to appreciate the real value of the work.

Impedance Networks.

Transmission Networks and Wave Filters. By T. E. Shea. Pp. xvii + 470. (London: Chapman and Hall, Ltd., 1930.) 32s. net.

THE study of impedance networks has acquired much importance during the past decade, as a result very largely of the pioneer work of G. A. Campbell on wave-filters. The literature of the subject has hitherto been scattered through the pages of patent specifications and technical journals, particularly the Bell System technical journal: the present very thorough account, which is particularly complete in its treatment of wave filters, will therefore be of the highest value to electricians. Although wave-filters have hitherto been used mainly in their practical applications to telephony, telegraphy, and wireless transmission, the precision with which they can be made to suppress some frequency bands while admitting others may render them of service in some branches of pure research.

Part I. deals with general principles, such as impedance-matching and the determination of iterative and image impedances—properties of asymmetric networks which correspond to the characteristic impedance of a uniform cable; propagation constants, the real part of which determines the attenuation of oscillations transmitted through the filter chain, while the imaginary part determines their phase change or velocity of propagation; and equivalences between various types of impedance combinations. Part II. deals with wave filters, as distinct from artificial lines for imitating cables, from retardation lines for producing progressive phase-change, and from attenuation equalisers for correcting distortion in telephony. It discusses the criteria for determining the 'cut-off frequencies' at the edges of the suppressed and transmitted frequency bands; the principal types of filter, particularly the 'constant-K' in which the product of the series and shunt impedances in each filter section is constant for all frequencies; the design of band-pass, low-pass, and high-pass filters; and the evaluation of the reflection losses which arise when a filter is not terminated by matched impedances.

Part III. is devoted to the transmission through impedance networks of transient impulses, such as telegraphic impulses, and gives *inter alia* an interesting analysis of the blurring caused in television by the fact that the width of the scanning aperture is not zero—a defect which can be remedied by the insertion of a suitably designed network. There are an excellent bibliography, numerical tables and graphs, a list of U.S. patents, and an index.

Although the wording of the book does not always strike an English reader as perfectly lucid, the author contrives to make his complicated subject clearly intelligible, and the mathematical treatment is simple and direct. The style in which the mathematical formulæ are set out suggests that they were originally typewritten with an ordinary typewriter, and leaves something to be desired. The choice of symbols is irritating: dashes, suffixes, and sub-suffixes appear and disappear like 'bats in a belfry', and the list of symbols on page xv omits the most puzzling of them. Nevertheless, as an intelligible exposition of subject matter which has not previously been summarised with anything approaching the present thoroughness, the book will be indispensable to all whom it concerns.

C. W. HUME.

Our Bookshelf.

Christ's Hospital: from a Boy's Point of View, 1864–1870. By the late Rev. W. M. Digues La Touche. Edited by his Brother. Pp. xii + 82 + 2 plates. (Cambridge: W. Heffer and Sons, Ltd.; London: Simpkin Marshall, Ltd., 1928.) 3s. 6d. net.

THE appointment of Mr. Hamilton Fyfe as the head of a university in Canada and of Mr. Flecker as his successor recalls one's mind to the famous school which the one is leaving and the other taking over. The Blue Coat School has always held a special place in the affections of English people, partly from the picturesque dress to which the boys remain loyally and proudly attached, partly from its old situation in the heart of London, partly from the lustre which a long array of distinguished ex-scholars have shed upon it. What school would not shine brighter in the light of Charles Lamb and Samuel Taylor Coleridge? It has since 1902 been housed in the most magnificent group of buildings provided for any school in England, and its efficiency in education reached its highest point under the able direction of its late chief.

The little book before us gives a lively and interesting account of the school in its old home from the pen of an 'old boy' now dead, the Rev. W. M. Digues La Touche, a member of one of the many gifted Huguenot families who came over from France

after the revocation of the Edict of Nantes. His father was a Shropshire clergyman and he himself returned there in mid-life in the same capacity. But he had added many things to the equipment of the average parson, for he was an enthusiastic and accomplished draughtsman, an ardent geologist, and a musician capable of training and conducting the village band and choral society. Evidently Christ's Hospital had done well by him, even in the rough and barbarous days which he describes. It is so evident in all he says that a spice of roughness is no drawback to a sound and even enjoyable education. The book is a welcome addition to the large literature which has arisen from Blue Coat surroundings. Every 'old boy' would wish to have it, and to the general student of education it has more than local interest. One striking feature which must have reached its highest point here is the list of special and esoteric names applied to the various boys, objects, and actions familiar in the school. In this vocabulary we go from the 'Grecians' at the top, down to the 'Trades' of each ward who brought up the food from the kitchens and even the 'Cakes' left on the boy's person by the cheerfully accepted canings. Can one have a really intimate and effective home or school without some such affectionate jargon?

F. S. M.

Penrose's Annual: the Year's Progress in the Graphic Arts. Vol. 33, 1931. Edited by William Gamble. Pp. xix+172+72+98 plates. (London: Percy Lund, Humphries and Co., Ltd., 1930.) 8s. net.

THIS ponderous volume is considerably thicker than any of its predecessors, presumably because of the larger number of examples of work that it contains. Of these examples, some, so far as one can judge, are very fine; but of course when the merit of a piece of work consists in copying an original as nearly as possible, one cannot really judge of it in the absence of the original.

We are very glad to see that Mr. A. J. Newton sets the good example of illustrating the results of the Peridak process by a graduated device, not a picture. Here we get a full range of tones with a patch of sensible size for each. This is a process of definitely controlling the reduction by means of Farmer's solution, in such a manner that dots that are completely joined may be reduced to mere pin points without losing their opacity. The screen negative is etched in nine stages. This tendency to complexity of method is also manifest in colour work. Theoretically, three colours are sufficient. Then for some time we got accustomed to four. In this volume there are specimens of pictures in up to eight colours, and from the nature of the examples we cannot see the advantage of running from the simplicity of three, or at most four, up to the complexity so nearly rivalling the colour work done before the three-colour era.

Mr. C. T. Jacobi has this year selected the Cambridge University Press for his historical article. He traces its development from A.D. 1521, when John Siberch printed the first Cambridge book. Dr. A. Ruppel, the Director of the Gutenberg Museum in Mayence on the Rhine, contributes an illustrated article on the Museum, past, present, and future. The editor gives his usual review and notes, summarising the progress of the graphic arts during the third of a century.

Grundlagen der praktischen Optik: Analyse und Synthese optischer Systeme. Von Dr. M. Berek. Pp. vii+152. (Berlin und Leipzig: Walter de Gruyter und Co., 1930.) 13 gold marks.

A NUMBER of circumstances have combined to bring the importance of applied optics to the fore in recent years. Unfortunately, research into the range of validity of some of the more important theorems has tended to lag behind the immediate needs of manufacturers, while, conversely, the practical optician has failed to appreciate the help which the applied mathematician—with workshop experience—can provide.

Prof. Berek is in a position to render great service in this connexion, in that he combines a first-hand knowledge of industrial conditions (and limitations) with an academic outlook upon physical optics. His book contains a number of very elegant theorems relating to image formation and synthetic optical systems, which should prove of considerable value in the design of microscopes and ophthalmic instruments. The latter have already benefited greatly from the classical work of Prof. von Rohr: it is gratifying to find the subject so much alive.

This is not a book that can be honestly recommended to junior students; its place is more in the post-graduate laboratory of technical colleges and in the research department of firms concerned with optical apparatus of high precision.

F. I. G. R.

Physik: ein Lehrbuch für Studierende an den Universitäten und technischen Hochschulen. Von Prof. Wilhelm H. Westphal. Zweite Auflage. Pp. xvi+571. (Berlin: Julius Springer, 1930.) 19·80 gold marks.

IN the second edition of his book, Prof. Westphal has retained the desirable features which were referred to in noticing the first edition (NATURE, July 6, 1929, p. 18). In particular, the first chapter is excellent, with its introduction to causality and the essence of hypothesis. This is clearly the way in which a text-book of physics should begin, and yet such an opening is all too rare.

As regards the rest, compared with the general high level, the portion dealing with thermodynamics seems a little uninspired. Would it not be possible to cut adrift from convention and attack entropy boldly from the axiomatic point of view of Carathéodory? Fear of the examiner is probably less acute in the German university than elsewhere. Again (p. 519), Debye's T^3 law is given without comment: Schaefer's reasons for doubting its validity at the lowest temperatures—where it is usually taken for granted—should surely have been mentioned.

The author writes with unusual clarity: many English-speaking students would do well to improve their physics and their German by using this book.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Ether and Relativity.

I OBVIOUSLY must not ask for space to discuss all the points raised in Sir Oliver Lodge's interesting letter in NATURE of Nov. 22, and so will attempt no reply to those parts of it which run counter to the ordinarily accepted theory of relativity. For I am sure nothing I could say would change his views here. But I am naturally distressed at his thinking I have quoted him with a "kind of unfairness", and should be much more so, had I not an absolutely clear conscience and, as I think, the facts on my side.

In the part of my book to which Sir Oliver objects most, I explained how the hard facts of experiment left no room for the old material ether of the nineteenth century. (Sir Oliver explains in NATURE that he, too, has abandoned this old material ether.) I then quoted Sir Oliver's own words to the effect that many people prefer to call the ether 'space', and his sentence, "The term used does not matter much".

I took these last words to mean, not merely that the ether by any other name would smell as sweet to Sir Oliver, but also that he thought that 'space' was really a very suitable name for the new ether. He now explains he was willing to call the ether 'space', "for the sake of peace and agreement". If I had thought it was only *qua* pacifist and not *qua* scientist that he was willing to call the ether 'space', I naturally would not have quoted him as I did, and will, of course, if he wishes, delete the quotation from future editions of my book. But I did not know his reasons at the time, and so cannot feel that I acted unfairly in quoting his own words verbatim from an Encyclopædia article.

Against this, I seem to find Sir Oliver attributing things to me that, to the best of my belief, I did not say at all, as, for example, that a mathematician alone can hope to understand the universe. My own words were (p. 128):

"No one except a mathematician need ever hope fully to understand those branches of science which try to unravel the fundamental nature of the universe — the theory of relativity, the theory of quanta and the wave mechanics."

This I stick to, having had much experience of trying to explain these branches of science to non-mathematicians. In the same way, if the material universe had been created or designed on æsthetic lines — a possibility which others have contemplated besides Sir Oliver Lodge — then artists ought to be specially apt at these fundamental branches of science. I have noticed no such special aptitude on the part of my artist friends. Incidentally, I think this answers the question propounded in the News and Views columns of NATURE of Nov. 8, which was, in brief: If the universe were fundamentally æsthetic, how could an æsthetic description of it possibly be given by the methods of physics? Surely the answer is that if the objective universe were fundamentally æsthetic in its design, physics (defined as the science which explores the fundamental nature of the objective universe) would be very different from what it actually is; it would be a *milieu* for artistic emotion and not for mathematical symbols. Of course, we may come to this yet, but if so, modern physics would seem rather to have lost the scent.

However, I am glad to be able to agree with much that Sir Oliver writes, including the quotations from Einstein which he seems to bring up as heavy artillery to give me the final *coup de grâce*: "In this sense, therefore, there exists an ether", and so on. On this I would comment that nothing in science seems to exist any more in the good old-fashioned sense — that is, without qualifications; and modern physics always answers the question, "To be or not to be?" by some hesitating compromise, ambiguity, or evasion. All this, to my mind, gives strong support to my main thesis.

J. H. JEANS.

Cleveland Lodge,
Dorking, Nov. 23.

Boric Acid in the Glaze of the Sealed Vases of Arezzo.

IT may be of interest to record a discovery I have made, with Dr Grassini, which should prove of importance in the study of old ceramics, and also of the commerce and industries of the Romans of the first century after Christ. My researches upon the antiquity of the boric acid bearing 'lagoni' and 'soffioni' of Tuscany led me to examine the glaze of the famous Arezzo pottery (*vasi sigillati aretini*). These vases are among the most beautiful and important of the artistic works of the Romans of the first century before and after Christ.

The constitution of that marvellous coral-like glaze, so bright and thin, many attempts at the reproduction of which have been made and about which so many hypotheses have been advanced, has always been something of a mystery. Dr. F. Keller,[1] a German worker, was the first to suggest that boric acid might be a constituent of the glaze, upon the assumption, based on experimental evidence, that good glazes could be obtained (excellent, to quote the author) only by using borax. His conclusions were not generally accepted, even by those who saw the results of his attempts to reproduce the old glazes. The question was still open. Nevertheless, the opinion was widely held that, in the glaze of the Arezzo vases, boric acid could enter as a constituent, and in the 'Storia della ceramica Greca', by Pericle Ducati, it is stated: "In Arezzo's manufactories, the application of a brilliant glaze, colourless, composed of silicates, iron oxide, and perhaps of borax, is also to be noticed". But no proof could be established; the historians of chemistry affirming, on the other hand, that borax was unknown to the Greeks and to the Romans.

I therefore made up my mind to try an *experimentum crucis* by analysing chemically the glaze of the Arezzo vases. This was not easy, since it was necessary to get a quantity of fragments of no artistic value; in addition, the glaze is only a thin layer, and it is difficult to detach it. Dr. A. Del Vita, the archæologist who, with his brother, so successfully attempted the revival in Arezzo of the famous Roman ceramic industry, came to my help by providing a good quantity of fragments from the potteries of "L(ucius?) Titi", and "Thursus", which were found during some trials made for research purpose, by Dr. De Vita, in an area situated under the walls of the northern side of Arezzo. Collaborating with Dr. R. Grassini, and in his private laboratory in Florence, the necessary analyses were carried out.

Accurate analyses of the glaze have led us to affirm with certainty that boric acid is found as a constituent part of the glaze, and not merely in occasional traces. It is, we think, the first time that boric acid has been certainly detected in products of that epoch;

it must be noted, on the other hand, that we have not found any boric acid in the glaze of Etruscan-Campanian fragments.

Prof. Xaver Landerer (born in Munich in 1809, died in Athens in 1883), of the University and Polytechnic of Athens, states that the Romans and Greeks were acquainted with boric acid, but I do not believe that his statements were based upon accurate analyses by himself or others. Whether the Romans extracted borax, mistaking it for other products, from Asia Minor or other places in the East, or whether they utilised, without knowing their nature, products of the actual 'lagoni', it is difficult to say. A detailed account of the present work, together with a full discussion of these questions, will appear elsewhere: we limit ourselves, for the time being, to recording the results of the present investigation, and expressing our thanks to those who are helping us in this difficult field. We would also urge the importance of extensive chemical and physico-chemical studies on the various ceramic, metallurgical, and similar products of antiquity, studies which, until now, have been very incomplete and fragmentary, and may throw new light upon so many vital questions.

Embryology and Evolution.

PROF. MACBRIDE, in his brilliant review (NATURE, Oct. 25, p. 639) of the recent embryological works by Dürken, Schleip, and Przibram, raises questions which are so fundamental in modern biology that I venture in all humility to interpose a word. Although I have not yet had the opportunity of reading these books, much of their work is already familiar ground, and Prof. MacBride's clear exposition renders reference to the originals unnecessary so far as these general questions are concerned.

My friend Prof. MacBride appears to have surrendered to the charm of Driesch's 'entelechy' as a directive agency in embryological development. But surely Driesch's method is the dangerous one of argument by exclusion. He says in effect, no mechanistic hypothesis yet brought forward will explain all the phenomena of development, therefore there must be some non-material agency at work. This, however, is an 'explanation' which explains nothing in any scientific sense. If it were to be accepted as an explanation, there would be no further incentive to experimental embryology. This is, indeed, the view which Prof. MacBride himself formerly took of Driesch's philosophy (see NATURE, vol. 92, pp. 291, 400; 1913).

But are the possibilities of a mechanistic explanation of development exhausted? I venture to think otherwise. The issue is the more important, because various writers, such as Rádl and Uexküll, endeavour to use Driesch as a means of decrying 'Darwinism', that is, evolution. Prof. MacBride's question, "If there be such a thing as evolution", leads one to wonder whether in his mind also an adherence to vitalism may lead to a questioning of evolution itself. Rádl, in his anti-evolutionary bias, goes so far as to say ("The History of Biological Theories", p. 187), "It is almost universally, though tacitly, assumed in biological text-books that organisms must have had a polyphyletic origin". I can only plead ignorance of any such 'text-book'. Again, he tells us (p. 388) that Darwinism was "completely rejected" by Driesch.

Turning to Uexküll ("Theoretical Biology", 1926), we find such statements as these. On p. 112 it is stated that whenever a vestigial organ has been tested, some function peculiar to it has always been revealed, and "it is to be hoped that 'vestigial organs' will soon disappear into oblivion". Again (p. 114), the framework of the cell "is an absolutely perfect machine", and "in this respect, there is no such thing as evolution". The first contradictory fact that occurs to one is the extremely primitive nuclei and mitotic mechanism of such organisms as the blue-green Algæ. But again (p. 164), "Every living creature is, in principle, absolutely perfect". Such statements savour more of medieval theology than of modern science. In this book we find (p. 238) that it was Mendelism which "swept the whole theory (of Darwinism) away"!

As is well known, Driesch's argument rests on those types of embryos in which the cells, when separated in the early stages of cleavage, are each capable of producing a complete embryo of smaller size. He argues that no machine can perform such feats, and that therefore, in short, the behaviour of such embryos cannot have a mechanical explanation. But what man-made machine is divided up into similar compartments, each having within it its own controlling centre? When those centres (the nuclei) are equipotential and are all moreover totipotent, why should there be surprise when each cleavage segment begins to develop as the original egg with its single nucleus began to develop?

Prof. MacBride agrees that emissions from the nucleus control development. Then why invent an entelechy to control these emissions? Is not the relation of the nuclei to the cytoplasm, and of the cells to each other and to the environment, sufficient to account for such differentiation of cytoplasm as takes place in development? Surely the facts of regeneration, remarkable as they are, would seem to lose some of their terrors when it is recognised that all the nuclei of an organism are in general totipotent.

Both Rádl and Uexküll adhere to the old conceptions of Weismann regarding the differentiation of nuclei during ontogeny, but such a view has long been obsolete and, as Prof. MacBride points out, the nuclei are to be regarded as undifferentiated during development. I reached a similar conclusion many years ago ("The Mutation Factor in Evolution", p. 297; 1915) on the basis of such mutations as *Œnothera lata*, which have an extra chromosome in every cell. Many similar cases have been discovered since. Driesch ("Science and Philosophy of the Organism", 1908, p. 154) regards the cambium of higher plants as a similar "equipotential system with complex potencies". This indeed appears to be true, but, so far as I am aware, botanists have never yet felt the need for an entelechy in their explanation of its characteristic activity. In the process of secondary thickening in an ordinary woody stem, secondary medullary rays soon begin to appear. This is because the cambium cells on certain radii change their activity and produce parenchyma cells instead of xylem and phloem. Has the entelechy changed its mind, or will it suffice to assume that with increasing diameter and circumference the altered spatial relationships between the tissues lead to a change in the activity of the cambial cells occupying certain positions?

The length to which such vitalistic conceptions can be carried is well exemplified by Uexküll, who, in his discussion of Mendelism, after adopting the current view that the chromosomes contain enzymes which in their turn initiate the development of

characters, makes the gratuitous assumption (l.c. p. 214) that these enzymes are themselves controlled by non-material impulses. We read (p. 216), "We may say that the genes are 'impulsive', but by that term we must not presume a physical energy, following the rule of causality; rather, we must understand the power to convert an extra-spatial and extra-temporal plan into a physical phenomenon". This seems pure mysticism, yet (p. 201) he accepts the usual conception that in Mendelian inheritance "a separation of the competing rudiments" takes place in germ cell maturation. What are these "competing rudiments" but material particles? After stating that Driesch "has proved that there is a framework present in the germ", Uexkull goes on to say (p. 209) that a framework is like a machine and cannot repair itself. It is important to point out that this also applies to the chromosomes. There is now clear evidence from various lines of observation and experiment that when a chromosome or a portion of one is lost it is never regenerated.

Prof. MacBride, in touching on the question of genes, states that Johannsen deplored "the damage and confusion of thought caused by the invention of the word 'gene'". There must be some further confusion of thought here, for it was Johannsen himself who invented the word gene ("Elemente der exakten Erblichkeitslehre", third edition, p. 165), as well as genotype and phaenotype. We find it more rational to accept the conception of genes spatially arranged in the chromosomes and distributed by mitosis to every nucleus during ontogeny, thus leading to an orderly development, than to postulate an entelechy the ways of which are past finding out, or a bundle of memories which seems an even more uncertain basis on which to explain the phenomena of ontogeny and regeneration.

Since Prof. MacBride accepts the conception of emissions from the nuclei as controlling development, and since we know that the nuclei of each species of animal or plant have a definite and characteristic morphological collocation of materials making up the chromosomes, might we not ask him to consider the definiteness in every detail of the structure of these bodies, as a possible basis for the orderliness which we behold in the successive stages of embryological development. That the essential substances in the chromosomes are autocatalytic in nature, is a view frequently held, and it appears to furnish an adequate mechanistic basis for the phenomena of development.

We fully agree with Prof. MacBride that Schleip's conception of an ultra-microscopic crystalloidal structure in the cytoplasm will not suffice to explain the phenomena of development and regeneration, but we have already seen that the known organisation of the nucleus appears to be sufficient, working in a cytoplasmic matrix which is relatively undifferentiated from species to species. The recent work on species-hybrids shows that in those cases, such as *Antirrhinum*, where Mendelian behaviour results, there is no cytoplasmic difference involved; whereas in many other experimental cases, both in plants and animals, the less nearly related species have their characteristic cytoplasm, as well as differences in the germ nuclei. It appears clear that in species differentiation nuclear differences arise first and cytoplasmic differences afterwards, as the nuclear differences become more pronounced.

We are fully impressed by Spemann's conception of 'organisers' in embryonic development, based chiefly on the more recent embryonic grafting experiments. But we take it that this need not lead to the conception that the organisers have an entelechy which dominates over the entelechy of the part on which they are grafted.

It is interesting to note that both Driesch and Przibram regard the stiffening or solidifying of the cytoplasm of the animal egg as an important element affecting development. For Driesch it limits the activities of the entelechy, and for Przibram it leads to the formation of 'apoplasm' which is not fully [illegible] ds plant embryoge[illegible] r, the conditions of stiffening in the cytoplasm appear to be quite the reverse. The meristem of a growing root or stem is composed of undifferentiated cells which are filled with dense and apparently stiff cytoplasm. Differentiation of the stelar tissues only begins in the older region of the stem or root, where the cells have taken in quantities of water and developed vacuoles which ultimately coalesce to form a large watery chamber with a thin peripheral layer of cytoplasm. It appears true that such secondary meristems as the cambium retain dense cytoplasm or develop it before they begin to divide, but their derivatives show a progressive increase in water content, and therefore in one sense at least in liquidity. These products of the meristems are, of course, the cells which become differentiated tissue elements.

R. RUGGLES GATES.

King's College,
Strand, W.C.2.

To answer Prof. Gates fully would require a philosophical treatise, for which I am sure no room could be found in NATURE. I shall endeavour to deal with his principal points as briefly as I can.

Prof. Gates asserts that Driesch assumed an entelechy because the facts of development could be explained by no mechanical hypothesis so far put forward; but that the entelechy "explained nothing" and was 'unscientific'. These are serious accusations to bring against a biologist of the eminence of Prof. Driesch. Prof. Gates's statement of Driesch's argument is incorrect. What Driesch said was that no *possible* mechanical hypothesis would explain development: for all such hypotheses in the last resort resolve themselves into the assumption of a "fixed constellation of parts" or, as I would put it, the juxtaposition in a fixed order of unlike molecules.

'Science' is only organised common sense, and if Driesch was driven to this conclusion by convincing logic, it is eminently 'scientific' on his part to say so. As to the entelechy explaining nothing, Prof. Gates should remember that *all explanation is comparison*—the ranging of less known with the better known. Prof. Gates does not believe that he himself is a mere mechanism; if he were, he could not carry out scientific reasoning. He knows that he possesses a personality which 'regulates' his bodily mechanism—and what Driesch's conclusion amounts to is that a rudimentary element of the same general nature exists in every organism. An eminently common-sense conclusion! For, as has been well said, the man who maintains that his brother or his cat is a mere mechanism, is either a fool or a 'physiologist'.

Prof. Gates agrees with me that nuclei are equipotential and that the nuclei control or 'organise' the cytoplasm, and these considerations, he thinks, afford a 'mechanical' explanation of development. On this point I shall only remark that it was precisely these considerations which led Driesch to his vitalistic hypothesis. I recommend Prof. Gates to re-read carefully "The Science and Philosophy of the Organism". The fact is that all so-called mechanical hypotheses of development surreptitiously introduce

vitalistic links into the chain of argument, but endeavour to cover them up by inventing technical names for them.

Prof. Gates admits that the cambium of the higher plants is an equipotential system, but says that no botanist as yet has postulated the existence of an entelechy. If Prof. Gates will read Prof. Bower's Bristol address to the British Association, he will encounter something suspiciously like the Drieschian entelechy.

I shall not follow Prof. Gates in his attack on Von Uexküll's "Theoretische Biologie", but will refer him to my review of that book which appeared in NATURE in July 1929.[1] Von Uexküll is one of our foremost comparative physiologists. His destructive criticism of the mechanistic position is, to my mind, unanswerable.

It is true, as Prof. Gates says, that Johannsen invented the word 'gene', but he lived to regret it, and his repudiation of it is contained in *Hereditas*, vol. 4 (1923), p. 133, to which I refer Prof. Gates.

Prof. Gates invites me to consider whether the conception of the chromosomes as composed of 'genes' which are 'autocatalysts' does not afford the explanation of development of which I am in search. The "orderly arrangement of genes" is a figment of the imagination; as Dürken has remarked, no one has ever seen 'genes' in a chromosome, which always appears when examined fresh to be a homogeneous rod of glutinous material. But if Prof. Gates were a zoologist instead of being a botanist, he would know that the assumption that 'genes' have anything to do with evolution leads to results, as in the case of *Drosophila*, that can only be described as farcical, and this assumption is repudiated by all those really conversant with the evidence for evolution.

The term 'autocatalysis' is a piece of bluff invented by the late Prof. Loeb to cover up a hole in the argument in his book, "The Mechanics of Living Matter". If we turn to the late Prof. Bayliss's book on enzyme action — and he is our foremost authority — we find a catalyst defined as something which causes a chemical action normally proceeding slowly to proceed quickly. All known chemical actions are inhibited by the accumulation of the products of the reaction. An 'autocatalytic' reaction, in which the products of the reaction accelerated it, must surely be a vitalistic one!

Prof. Gates has kindly and sympathetic concern about my 'salvation' as an evolutionist. Let me reassure him on this point: I am a thorough believer in evolution. I admit that statements of both Driesch and Uexküll give colour to his complaint that they repudiate evolution altogether. It was part of the object of my review to show that the concept of entelechy could be further analysed, and that entelechies could be brought into orderly relation to one another and fitted into a scheme of evolution.

Absorption of Sound at Oblique Incidence.

IN the issue of NATURE for Sept. 6, Dr. P. R. Heyl directs attention to a disagreement between theoretical conclusions concerning the absorption of sound by porous bodies at oblique angles of incidence.

The theories to which he refers are those given by Sir Joseph Larmor[1] and myself.[2] Dr. Heyl states that "For grazing incidence, Larmor finds that the absorption should be infinite, while Paris comes to the conclusion that it should be zero".

The disagreement is due to an unfortunate 'approximation' which occurs in Sir Joseph Larmor's calculation.[3] It is there shown that

$$\frac{u_1 - u_2}{u_1 + u_2} = \frac{k'}{k}\,\frac{a}{\cos\iota}, \qquad (1)$$

where u_1 and u_2 are the particle velocities in the incident and reflected waves respectively, k'/k is the ratio of the wave-length in the incident sound to the wave-length in the pores, a is the proportion of the reflecting surface occupied by the pore openings, and ι is the angle of incidence. The 'degree of stifling of the sound' (that is, the coefficient of absorption) is stated to be "$(u_1^2 - u_2^2)/u_1^2$ or approximately $(u_1^2 - u_2^2)/\frac{1}{4}(u_1 + u_2)^2$" (an obvious misprint which occurs in the original paper is corrected). This leads to an absorption coefficient $(k'/k)4a/\cos\iota$ which increases with obliquity and tends to become infinite at grazing incidence — a result which is manifestly wrong, since for physical reasons the coefficient cannot in any circumstances be greater than unity. The source of trouble is in the approximation. From the equation (1) quoted above we have

$$\frac{u_2}{u_1} = \frac{\cos\iota - (k'/k)a}{\cos\iota + (k'/k)a}, \qquad (2)$$

whence, without approximation, the absorption coefficient is

$$\frac{4(k'/k)a \cdot \cos\iota}{\{\cos\iota + (k'/k)a\}^2}, \qquad (3)$$

which tends to zero as grazing incidence is approached. It is clear from (3) that the so-called approximation consists in neglecting $(k'/k)a$ in comparison with $\cos\iota$ for all values of ι between 0 and $\pi/2$.

It appears therefore that when no approximation is made, Sir Joseph Larmor's results are in agreement with those given in my paper of 1927. In fact, the equation (1) which expresses the relation between the amplitudes of the incident and reflected waves has precisely the form of my equation[4] (3.4) deduced by the aid of 'acoustical admittance'.

It may be observed that $(k'/k)a = u/(p/a\rho)$ where u is the component of particle velocity normal to the reflecting surface, p is the pressure at this surface, a is the velocity of sound in air, and ρ is the density of air. This follows at once from equations on p. 234 of Sir Joseph Larmor's paper.[5] Hence $(k'/k)a = u/V$ where V is the particle velocity in a plane progressive wave in which the pressure is p. The possible values of $(k'/k)a$ therefore lie in the range zero to unity, that is, in the same range as the values of $\cos\iota$. Thus, from (2) we see that there are always values of ι for which u_2 is negligible compared with u_1, and for every value of $(k'/k)a$ there is a value of ι for which u_2 vanishes and the incident sound is totally absorbed.[6] The argument applies only to the ideal case when k' is real. For actual materials k' is expected to be complex, and then, as shown elsewhere, the absorption should be a maximum for some particular angle of incidence.

Glucose and the Structure of the Cycloses.

THE cyclohexanols $C_6H_{12-n}(OH)_n$ and their methyl derivatives are of considerable interest from the point of view of biochemistry. It has been known for some time that these substances can, according to theory, exist in a great number of isomeric forms.[1] The following table shows the number of possible isomers

for various values of n, on the assumption of a plane ring structure for the cyclohexane nucleus:

TABLE I.

CYCLOHEXANOL ISOMERS (PLANE RING).

n	Substitution.	Active (in pairs)	Inactive.	Totals	
1	1.	0	1		1
2	1.2.	2	1	3	
.	1.3.	2	1	3	
.	1.4.	0	2	2	8
3	1.2.3.	2	2	4	
.	1.2.4.(1.2.5.)	8	0	8	
.	1.3.5.	0	2	2	11
4	1.2.3.4.	8	2	10	
.	1.3.5 6.	4	4	8	
.	1.3.4.6.	4	3	7	25
5	1.2.3.4.5.	12	4	16	16
6	1.2.3 4.5.6.	2	7	9	9

The natural occurrence of the cycloses is summarised as follows: There are two inactive cyclohexanhexols, *i*-inositol and scyllitol, which are definitely known to occur. The monomethyl *i* inositols, bornesitol, mytilitol,[2] and sequoyitol,[3] and two dimethyl derivatives are also recorded. The two active inositols as such have been reported only in the racemic form in the berries of the mistletoe, but their methyl derivatives, quebrachitol and pinitol, are of more general occurrence.

The dextrorotatory pentol known as *d*-quercitol has been obtained from several sources and its lævorotatory diastereomer has been found in the leaves of *Gymnema sylvestre*. One active tetrol, betitol, the constitution of which has not yet been discussed, is reported to occur in the sugar beet.

While it cannot be said that the search for cycloses has been exhaustive, very considerable work has been done which would lead to their discovery.[4] It is therefore not unreasonable to suppose that at least a majority of the naturally occurring cycloses have been discovered. It remains then to explain the discrepancy between the seven known cycloses with four or more hydroxyl groups and the fifty which are theoretically possible.

In view of the widespread occurrence of these substances in Nature, one is tempted to look for some common function or property which will limit the number of cycloses which can occur. Without considering its plausibility, let us assume that in Nature the cycloses and their methyl derivatives have their origin in glucose, or at least are chemically closely connected with some substance which contains in its structure the configuration: *

$$\begin{array}{ccccccc} & & \mathrm{OH} & \mathrm{H} & \mathrm{OH} & \mathrm{OH} & \\ & & | & | & | & | & \\ \mathrm{XYZC} & - & \mathrm{C} & \mathrm{C} & \mathrm{C} & \mathrm{C} & -\mathrm{CUVW} \\ & & | & | & | & | & \\ & & \mathrm{H} & \mathrm{OH} & \mathrm{H} & \mathrm{H} & \end{array}$$

Let us now determine which of the theoretical isomers of Table I. can give rise to the glucose configuration. In Table II. the number of isomers which satisfy this condition is compared with the number actually found in Nature. Of course, the monol, diols, triols, the 1.3.5.6 tetrols, and the 1.3.4.6 tetrols cannot contain the required arrangement of hydroxyls.

* We do not concern ourselves with the substitution of the end carbon atoms or with the sign of the activity. Thus the above formula might apply to *d*- or *l*-glucose, or to *d*- or *l*-gulose. This ambiguity does not have any bearing on the present argument.

TABLE II.

n	Activity	Theory.	Found.
4	inactive	0	..
..	dextro	1	1
..	lævo	1	.
5	inactive	1	..
.	dextro	3	1 †
..	lævo	3	1 †
6	inactive	3	2
..	dextro	1	1
.	lævo	1	1

† These are not antipodes, so that two models are represented.

We see from this table that of the fourteen cycloses required by the present theory, seven have been found. This agreement is surprisingly good when we remember that no account has been taken of the possible effect of the end groups in the formation of the ring. Any further condition can only reduce the number of isomers, so that the data in Table II. correspond to the maximum number of isomers consistent with the present assumption.

I am aware that the assumption of a puckered ring or a ring of any lower symmetry leads to a considerable increase in the number of possible isomers. Any criticism on this account is, however, equally well a criticism of most of the results of stereochemistry, and therefore need not be taken into account until circumstances warrant a more general view of the whole subject.

Of course, the theory that *i*-inositol is closely related physiologically to glucose is by no means new.[4] It provides an explanation of the association of glycosuria and inosituria in both pathological and experimental polyurias. Needham[5] has shown that inositol is synthesised in the embryonic development of the chick; and that in this case the maximum of the inositol time curve can be nearly doubled by the injection of glucose at the beginning of the development. Needham[6] has also shown that the dogfish embryo synthesises scyllitol in a similar manner, although the effect of glucose still remains to be investigated.

It is important to note here that the present assumption is in agreement with the structure arrived at for *i* inositol by S. and T. Posternak.[7]

A Relation between the Radial Velocities of Spiral Nebulæ and the Velocity of Dissolution of Matter.

IN a letter in NATURE of Nov. 8, p. 722, Prof. A. Haas proposes to relate the rate of expansion of the universe to the rate of 'disintegration' of matter by using Einstein's formula,

$$M = \frac{2}{\pi} R \text{ (gravitational units)} \quad . \quad . \quad (1)$$

and taking derivatives with respect to the time t.

Apart from the fact that this would give a negative velocity, that is, a contraction, the method itself seems to be illegitimate. Equation (1) is derived on the explicit assumption that R is not a function of t. When R is a function of t, (1) must be replaced by

$$\left(\frac{dR}{dt}\right)^2 + 1 = \tfrac{1}{3}R^2\lambda + \frac{4M}{3\pi R} \quad . \qquad (2)$$

where λ is Einstein's cosmical constant.[1] From (2) and related equations Eddington[2] has shown that Einstein's universe is unstable, so that when once disturbed it will expand or contract even if the total mass remains constant. He has further shown that if the initial disturbance were a conversion of matter into radiation it would actually start a *contraction*.

Prof. Haas does not state whether he is considering the *proper* mass or the *relative* mass. The latter does not change when matter is converted into radiation. If the proper mass is to be understood, a relation of his proposed type might hold good, apparently, only if λ were to vary in a suitable manner with the total amount of matter present. I am not aware that such a possibility has ever been suggested.

[2] *Mon. Not. Roy. Ast. Soc.*, **90**, p. 668; 1930.

A. HAAS deduces the equation:

$$v = 1{\cdot}1 \times 10^{-49} M,$$

where v represents 'cosmical velocity' and M the mass of the universe.[1] Taking $M = 1{\cdot}8 \times 10^{57}$ gm. he obtains $v = 2000$ km. per second and then says: "This value agrees well with the magnitude of the velocity with which the farthest spiral nebulæ appear to recede from us".

As against this, I find that according to more recent investigations the mass of the universe is considerably less than $1{\cdot}8 \times 10^{57}$ gm. According to A. S. Eddington[2] we may assume that $M = 2{\cdot}3 \times 10^{55}$ gm. If we insert this value we obtain only $v = 25$ km. per second.

In the near future the *Zeitschrift für Physik* will publish my paper: "Einige Folgerungen aus den neuesten Ansichten von E. C. Stoner und von E. A. Milne über das Innere der Sterne". In that article, among other subjects, I deal with the problem of the dissolution of matter, but from a totally different point of view from that of A. Haas.

Evidence for Quadripole Radiation.

THE $S \rightarrow D$ transitions which occur in the alkali spectra are forbidden by the ordinary selection rules for the azimuthal quantum number. As they are still observable in absorption, the question arises whether they are due to the action of external electric fields and are still a dipole radiation from a perturbed atom, or whether they are due to quadripole radiation. Rubinowicz has calculated the Zeeman selection rules for quadripole radiation; they differ from the ordinary rules in that the change in the magnetic quantum number may have the values ± 2 in addition to the ordinary ones $0, \pm 1$. The polarisation also is quite different.

I have observed the transverse Zeeman effect of the 4642·17-4641·58 potassium doublet, which is an $S \rightarrow D$ combination, and I have been able to show that its Zeeman pattern agrees with the predictions of Rubinowicz for quadripole radiation and not with those for dipole radiation. This transition is thus shown to arise from quadripole radiation.

Details will be published elsewhere.

The Carbohydrate Complex of Serum Proteins and the Clinical Determination of 'Bound Sugar' in the Blood.

IN connexion with the reference to my work (Rimington: *Bioch. J.*, **23**, 430) upon the isolation of a carbohydrate complex from blood-serum proteins, made in an article in NATURE of Nov. 1, p. 704, it may be of interest to state that I have now extended these observations, with the consequence that I have somewhat modified my earlier conclusions.

The complex obtained from the proteins of horses' serum appears to be a *tri*saccharide structure (possibly polymerised) and not a *di*saccharide as originally suspected. This conclusion was announced to the Biochemical Society on May 17 of this year, and is to be found in the *Proceedings* of that Society published in *Chemistry and Industry*, May 23, 1930, p. 440.

Each molecule of glucosamine is associated with two molecules of mannose, thus giving a substance with the empirical formula $C_{18}H_{33}NO_{15}$ and containing 2·78 per cent nitrogen. A similar trisaccharide complex, which appears to be identical with that already described, has also been isolated from the mixed serum proteins of ox blood. All my preparations are optically inactive.

It is of interest that the nitrogenous impurity which was found to be present in the substance originally isolated proved to be histidine. For its complete removal prolonged and vigorous hydrolysis is required. Since the carbon and hydrogen content of histidine differs little from that of the sugar which was being isolated, the fact that its presence was unsuspected is capable of explanation.

More recently I have attempted to prepare sufficient of the so-called mucoid of blood serum to examine it for associated carbohydrate material. In view of Levene and Mori's recent findings in the case of ovomucoid (*J. Biol. Chem.*, **84**, 49), it seems possible that this protein of the serum, also, may prove to be carbohydrate containing.

Finally, I should like to add that the discovery of these complexes in serum albumin and globulin affords a satisfactory explanation of some of the contradictory observations of various authors upon the 'bound sugar' of the blood. Alkaline hydrolysis of the proteins leads to a non-reducing complex which is also unattacked by enzymes; acid hydrolysis, on the other hand, yields reducing substances. Both glucosamine and mannose form an osazone identical with glucosazone, and such has frequently been isolated from the hydrolysed protein fractions of serum, but it is incorrect to assume, as has frequently been done, that the protein sugar is thus proved to be glucose.

Certain quantitative discrepancies between the results of various authors can be similarly explained. Bierry and Rathery (*C. R. de la Soc. Biol.*, **83**, 1890) give the figures for the protein sugar of horse plasma as about 0·13 per cent; Dische (*Bioch. Z.*, **202**, 74) finds it to be about 0·22 per cent. The former authors deproteinised their solutions with a mercuric nitrate reagent, which also precipitates glucosamine, whilst

Dische's figure was arrived at when using phosphotungstic acid as the protein precipitant.

The 'bound sugar' of the blood may have a physiological significance (Glassmann; *Zeit. physiol. Chem.*, **150**, 16, and **158**, 113).

A further communication on this subject will be published shortly.

Natural Selection Intensity as a Function of Mortality Rate.

IN NATURE of May 31, Prof. Salisbury points out that most of the mortality among higher plants occurs at the seedling stage, and concludes that natural selection is mainly confined to this stage. I believe, however, that this apparently obvious conclusion is fallacious, for the following reason:

Consider two pure lines A and B originally present in equal numbers, and with a common measurable character, normally distributed according to Gauss's law in each group. Let the standard deviations of the character be equal in each group, but its mean value in group A slightly larger than that in group B. Johansson's beans furnish examples of this type of distribution. Now let selection act so as to kill off all individuals in which the character falls below a certain value. I think that this type of artificial selection furnishes a fair parallel to natural selection, in which chance commonly plays a larger part than heritable differences. Let x be the proportion of individuals eliminated to survivors, and $1+y$ the proportion of A to B among the survivors, so that x measures the intensity of competition, y that of selection.

Then when x is small y is roughly proportional to it. Thus when x increases from 10^{-4} to 10^{-1}, y increases 200 times. But when x is large y becomes proportional to $\sqrt{\log x}$. In consequence y only increases 9 times when x increases from 1 to 10^{12}, and is only doubled when x increases from 1 to 1800. In other words, when more than 50 per cent of the population is eliminated by natural selection, the additional number eliminated makes little difference to the intensity of selection. The theory, which I hope to publish shortly, has been extended to cover cases where the standard deviations differ, and also where populations consist of many genotypes. In general y changes its sign with x, but when x is large y never increases more rapidly than $\log x$.

Careful mathematical analysis seems to disclose the extraordinary subtlety of the natural selection principle, and merely verbal arguments concerning it are likely to conceal serious fallacies.

The Exit of *Leishmania infantum* from the Proboscis of *Phlebotomus perniciosus*.

SANDFLIES, *P. perniciosus*, infected with *Leishmania infantum* on a hamster, were allowed to feed on a solution of citrate by Hertig's method. This method consists of inserting the biting apparatus of living sandflies into a capillary in such a way that the mouth parts go through all the movements of piercing. In some species these movements in the Hertig apparatus are followed by activity of the pumping apparatus of the buccal cavity and pharynx which results in the ingestion of fluid. In the case of *P. perniciosus*, the mouth parts go through all the actions of piercing, but the insects seldom ingest fluid in the Hertig apparatus.

Fifteen sandflies from five to thirteen days after the infecting feed were placed in the Hertig apparatus. After an interval of one to three minutes, the sandflies were removed and the fluid in the capillary was examined. In six cases (9-10 days after the infecting feed) the fluid was found to contain flagellates. The number of flagellates found varied from one to hundreds, but in all cases the number recovered from the biting parts was very small as compared to the enormous numbers afterwards found in the dissected sandflies. In contrast to the flagellates from the midgut and œsophagus, which are very active, those recovered from the biting parts are sluggish and many of them quite motionless.

The above observations prove that *L. infantum* can leave the biting parts of *P. perniciosus* during the act of biting and enter a new host in the absence of any active interference on the part of the latter. We suggest that this accounts for the main peculiarity of Mediterranean kala-azar, that is, its relative frequency in infants less than twelve months of age.

and Hebrew University of Jerusalem.

Elements present in Animal Tissues.

IN a letter published in NATURE of Nov. 15, Mr. A. Chaston Chapman announces the interesting discovery of antimony in an animal. He refers also to the known presence of vanadium and arsenic in certain animal tissues. We purposely omitted from our letter to NATURE of Nov. 1 reference to a number of other elements which have previously been recorded as occurring in animal tissues but which have not up to the present been detected in our work, for reasons already given by one of us[1]. They are the following: Aluminium, zinc, boron, and silicon, from numerous animals; gold in mammals[2]; titanium in an ascidian[3]; bismuth[4] and tin[5] in human organs; vanadium, not only in ascidians, but also in a holothurian[6]. In addition, Dr. J. Needham has directed our attention to records of molybdenum[7] and uranium[8] in hens' eggs.

English Equivalents of *Eigenfunktion* and *Eigenwert*.

MR. C. N. HINSHELWOOD suggests in NATURE of Oct. 18, p. 604, that the English equivalents of *eigenfunktion* and *eigenwert* should be *proper function* and *proper value*. Having shown how to develop the functions used by Schrodinger (see, for example, my paper in the *Phil. Mag.*, vol. 6, July 1928), may I again suggest from the nature of the Heaviside operator method disclosed that the terms to employ are *parametrals* and *parametral functions*.

A. PRESS.

New York, Nov. 3.

Intense Magnetic Fields and Low Temperature Research.*

By Sir ERNEST RUTHERFORD, O.M., P.R.S.

EXPERIENCE has shown that the encouragement of research by minor grants for special apparatus and material is in reasonable measure provided for by the Government grant to the Royal Society, supplemented from the Society's own research funds. The grants to individual investigators from such sources are usually small but suffice to assist materially important researches of a limited scope. The situation, however, is very different when we consider large scale investigations of a pioneering character, which may require considerable financial support extending over a period of years in order to provide the necessary apparatus and technical assistance to bring the investigation to a definite conclusion. Few of our universities or other scientific institutions are sufficiently well endowed to support large scale researches of this kind, even when the research appears of marked promise and when the idea and the man are forthcoming. In considering the best method of utilising the balance of the Society's present resources, the Council of the Royal Society has decided that it can best help the advance of science by assisting major researches of this character, and, after careful consideration, was impressed with the fundamental importance of the researches at present being carried on by Dr. P. Kapitza, at Cambridge, and the need for continuing this work on a more permanent basis.

It may be helpful at this stage to give a brief history of the origin and development of the work on which Dr. Kapitza has been engaged for the past eight years. Trained as an electrical engineer, Dr. Kapitza was lecturer in physics in the Petrograd Polytechnical Institute from 1918 until 1921. In 1921 he came to England and commenced research work in the Cavendish Laboratory, Cambridge. In 1922 he began experiments to test the possibility of obtaining intense magnetic fields by sending very strong currents through a coil for such a short interval that the heating effect in the coil is restricted to a permissible value. With the assistance of a grant from the Department of Scientific and Industrial Research, special accumulators were constructed to give the necessary intense currents for a short interval of about $\frac{1}{50}$ sec. In this way, fields up to 200,000 gauss were obtained, and it was found practicable to carry out experiments by this method, for example, on the Zeeman effect and on the deflection of α-particles.

In order to carry these experiments still further, it was necessary to have a method of obtaining currents still larger and more under control. For this purpose, a generator of special design was constructed which gives, on short circuit, a current of about 70,000 amperes. The heavy current from the generator is passed for about one-hundredth of a second through a coil and is then broken by means of a specially designed automatic break. The Department of Scientific and Industrial Research gave a very substantial grant for the construction of this apparatus, while Sir William Pope kindly provided a temporary laboratory to install the plant and to carry out the experiments. In 1926 the laboratory was opened formally by the late Lord Balfour, then Lord President of the Council, who had throughout taken an active interest in promoting these large scale experiments. This pioneering investigation, which was carried out in connexion with the Cavendish Laboratory, was only made possible by the generous and bold support of the Department of Scientific and Industrial Research, which, up to the present, has defrayed the complete cost of the apparatus and of the subsequent investigations.

One of the chief difficulties in these experiments has been to construct a coil strong enough to withstand the enormous disrupting forces which arise when a large current is passed through it. A number of coils have been constructed which give magnetic fields of between 300,000 and 400,000 gauss over a volume of about 3 c.c. There appears to be no inherent difficulty why fields of the order of 1 million gauss should not be obtained, when called for, by this method. As the current through the coil only lasts for about $\frac{1}{100}$ sec., oscillograph methods are used to determine the strength of the current and magnetic field and to follow the changes in the properties of the material under investigation. There is no special difficulty in conducting experiments with these momentary fields. In fact, a single photograph, obtained in $\frac{1}{100}$ sec., may give a complete quantitative record of the magnetic effects produced in a material over a wide range of magnetic field.

The application of these new methods of producing intense magnetic fields opens up a wide field of research where all magnetic properties can be examined in fields ten to thirty times greater than those hitherto available by the use of electromagnets.

As soon as the apparatus was in working order, experiments were begun to investigate the change of resistance of crystals of bismuth in these intense magnetic fields from atmospheric temperature to that of liquid air. This was followed by an extensive investigation of the behaviour of a large number of metals under corresponding conditions. In general, it was found that the change of resistance was at first approximately proportional to the square of the magnetic field, but above a certain critical field, which varied from metal to metal, the change of resistance tended to become linear. On the basis of these new results, Dr. Kapitza has suggested a new way of looking at the phenomena which underlie the electrical conductivity of metals and its variation with temperature. Preliminary experiments have also been made on the action of these strong fields on the paramagnetism and diamagnetism of certain substances, while a new and sensitive apparatus has been constructed to study magnetostriction effects. An

* Excerpts from the presidential address to the Royal Society delivered at the anniversary meeting on Dec. 1.

account of the apparatus and the experimental methods, together with the results of some of these investigations, has been published by Dr. Kapitza in the *Proceedings* of the Royal Society.

Magnetic phenomena are shown in their simplest form at very low temperatures when the complications due to the motion of the atoms and molecules are largely avoided. In order to obtain temperatures still lower than that of liquid air, a liquid hydrogen plant has been installed during the present year, and is now in working order. Preliminary arrangements have been made to install a liquid helium plant when this is required for the investigations.

The grant given by the Department of Scientific and Industrial Research for carrying out these researches expires in a few years, while the laboratory temporarily lent for the purpose of these experiments is now required by the Chemical Department of the University. The Department of Scientific and Industrial Research, by its broad-minded and far-seeing action, has done a great service to science in thus supporting, through their initial stages, investigations having no obvious or immediate application in practice or industry. Their support for an indefinite period, however, could scarcely be part of the Department's policy. On the other hand, it appeared to the Council of the Royal Society that investigations of this kind, in which new fields of knowledge are being opened up by new methods, had a peculiarly strong claim for support from those funds which the Society was holding ready for the furtherance of fundamental researches in pure science.

The Council of the Royal Society, in addition to appointing Dr. Kapitza to a Messel professorship, has therefore agreed to offer the University of Cambridge the sum of £15,000 for the building of a suitable laboratory within the next three years, provided the University was prepared to offer an appropriate site and to defray the running expenses of the new laboratory. If the University of Cambridge concurs with these proposals, the Royal Society will thus have been instrumental in founding a new and up-to-date laboratory, primarily designed for carrying out researches in intense magnetic fields, but at the same time providing the essentials of a modern cryogenic laboratory for the study of magnetic and other effects at the lowest attainable temperatures.

The name of the new laboratory at Cambridge has not yet been settled, but it would be appropriate if it indicated the connexion with the Royal Society and with the late Dr. Ludwig Mond, whose bequest furnished the income from which the cost of the laboratory will be defrayed. It should be noted that among the purposes indicated in the will of Dr. Mond for the use of his bequest was "erecting new laboratories".

It will be remembered that, thirty years ago, Great Britain was pre-eminent in the study of effects produced on matter by the low temperature produced with the aid of liquid hydrogen. It will be recalled that the late Sir James Dewar, with the technical assistance of Mr. Lennox, first produced liquid hydrogen in quantity in the laboratories of the Royal Institution in 1898, and in 1899 the first solid hydrogen was obtained. It was so early as 1893 that Dewar devised the vacuum flask which has proved to be of such fundamental importance in the technique of low temperatures and has so greatly simplified the handling of liquid gases. It is of interest to note that it was decided in 1902 to construct a liquid hydrogen plant, of capacity of about five litres of liquid hydrogen per hour, as a British Government exhibit to the St. Louis Exposition in 1904. This plant was placed in the competent hands of Mr. (now Sir) Joseph Petavel, and I well remember the interest of his demonstrations of the properties of liquid hydrogen at that Exhibition. Some time later, a small liquid hydrogen plant was installed by Dr. M. W. Travers, in the laboratory of the late Sir William Ramsay at University College, London.

In the meantime, an efficient cryogenic laboratory had been established at Leyden, under the direction of the late Prof. Kamerlingh Onnes. His success in liquefying helium and also the wide range and importance of the investigations carried out on the effects of low temperatures on the properties of matter are well known. It was only a few years ago that Prof. W. H. Keesom, who followed Onnes in the charge of this laboratory, was successful in producing solid helium.

A few years ago, owing to the energy and enthusiasm of Prof. J. C. McLennan, liquid hydrogen and helium plants were installed in the University of Toronto, and have proved their utility in a number of important researches. In recent years modern equipment for the liquefaction of hydrogen and helium has been installed in the Reichsanstalt, Berlin, by Dr. W. Meissner, and very valuable results have been already obtained. Dr. Franz Simon, of the University of Berlin, obtains the temperature of liquid helium by an ingenious method involving the use of liquid hydrogen and the absorption of helium gas by charcoal.

I am sure it will be gratifying to the Society to know that we may soon expect to have an up-to-date cryogenic laboratory on a small scale in Great Britain. I believe that it is in helping such important schemes of research that the Society can best utilise any research funds which it already possesses or which may become available in the near future. It not infrequently happens that a promising line of research or the development of a new method may be held up or abandoned because of the difficulty of obtaining adequate financial support. In some important directions, advance can only be made with the help of technical assistance in the construction and use of special apparatus, in some cases on an almost engineering scale.

It is by the encouragement and support of such major researches, especially in their initial stages, that the Society can be of great service in helping the advance of fundamental science in Great Britain. Along such general lines, it is not difficult to foresee that the Society will exert an ever-increasing influence on the progress of science and thus promote still further the original intentions of its founders.

News and Views.

ADMIRABLE sentiments were expressed by the Prime Minister when proposing the toast of 'The Royal Society' at the anniversary dinner on Monday last. Readers of NATURE must be familiar with, and possibly weary of, our continual insistence upon the use of scientific knowledge in the service of the State and of scientific method in administration. It is encouraging, therefore, to find Mr. Ramsay MacDonald expressing himself in entire sympathy with the view that public administration without science may be little more than a collection of words and phrases which can never lead a nation to security and prosperity. We are glad to record the words in which he stated this conviction: "The Royal Society", Mr. MacDonald said, "has stood pre-eminently for experimental knowledge, for the testing of every dogma whenever a competent witness arose to bring that dogma to the bar of reason and experiment. Until in our public life we can catch up the same spirit, the same rationality, the same conception of how truth is to be discovered and reality reached, and those who are engaged in public work and in government acquire the same frame of mind and adopt the same methods that the scientists adopt in their laboratories, government will be feeble, uncertain, and misleading. I make bold to offer the claim that science does not merely deal with the conception of the universe, with biochemistry, or with the conception of human nature, but that when science has claimed its full field, in all its width and length, it will claim to deal with governments and with administrations, and will assault and attack successfully those tremendously interesting and intricate problems of how to handle great masses of men, not by rule of thumb, not by the passing emotions of the day, but by a careful study of the permanent psychologies, emotions, leanings, and allurements of the human mind."

Now that Mr. MacDonald is himself a fellow of the Royal Society and has publicly declared his belief in the application of the methods of scientific inquiry to government, we may perhaps expect to see the principle put into practice more clearly than it is usually. The position of the dyestuffs industry, for example, might be considered on the Baconian plan of collecting facts and arriving at conclusions from them, instead of being decided upon political grounds. Attention might also be given, as was pointed out in a leading article in NATURE of Nov. 22, to the ethnology, social anthropology, and customs of the Indian peoples in connexion with the Round Table Conference now sitting in London. These are two opportunities which present themselves for consideration in the light of ascertained knowledge; and we may perhaps now hope that the Prime Minister will take advantage of them. In science, the test of a principle is the fulfilment of a prediction based upon it, and when we see that standard applied to political promises there will be more faith in democratic government than exists in most scientific circles to-day.

IN a letter addressed to the Prime Minister jointly by fifteen professors of chemistry in British universities, a strong case for reconsideration of the Government's decision to allow the Dyestuffs (Import Regulation) Act to lapse is cogently presented. The point of view is industrial as well as educational, for so closely is organic chemical research linked to the prosperity of organic chemical industry that it is impossible to consider one except in relation to the other. Moreover, the dyestuffs industry, which was the first industrial result of the development of organic chemistry into a systematic science, provided the experience and remains the pivot for the development of other branches of synthetic chemical industry: in no other branch of industry has there been such a clear repercussion between the art of the manufacturer and the science of the schools. The signatories are just those persons who are best qualified to express an opinion on the support which organic chemical industry affords to the advance of chemical knowledge, and they have declared that the existence of flourishing schools of organic research in the universities is indeed dependent on the demands made by the industry for the services of their students. Further, they insist that the salvation of many great industries of national importance depends on the application of scientific methods. They claim that the best training school for the future technologists and administrators of many of these industries is the organic chemical laboratory. Hence anything which tends to check the growth of the schools of organic chemistry is a blow at the future of a great many industries besides those most obviously or immediately concerned.

PRESENTING the report of the Council at the annual general meeting of the British Association of Chemists at Liverpool on Nov. 22, the general secretary, Mr. C. B. Woodley, showed that there has been a steady advance in every department of the Association's established activities. Mr. H. T. F. Rhodes referred to the position of the dyestuffs industry, remarking that the Council of the Association has not yet definitely decided what action should be taken, but that it desired to assist the Government so as to ensure that the dyestuffs industry should not suffer as a result of the lapsing of the Dyestuffs (Import Regulations) Act of 1920. He said that the future of the organic chemical industry, and consequently the supply of adequately trained organic chemists, depends upon an efficient dyestuffs industry; if it suffers, the efficiency of all industries depending upon organic chemistry will suffer. Allusion was again made to this important matter in Mr. F. Scholefield's presidential address. It is obviously impossible, said the president, for any individual or group of individuals not in full possession of all the facts to arrive at any decision as to the extent to which it may be desirable to protect the industry against foreign competition, or if it is necessary to protect the industry at all. There is no doubt, however, that a successful dyestuffs industry is the very backbone of the whole organic chemical industry, and that the research carried on in organic chemistry is very largely applied to dyestuffs. This has naturally

stimulated interest in applied organic chemistry, and has resulted in improved facilities for training organic chemists and in the attraction of suitable recruits to the ranks of the profession of chemistry

MR. SCHOLEFIELD, continuing his presidential address to the British Association of Chemists, criticised chemical training in Great Britain, alleging that "the newer universities are showing a tendency to model themselves on Oxford and Cambridge, and to be too keen on purely academic studies", whilst an investigation into technical education on the Continent, and particularly in Russia, shows that excellent work is being done. The Association should advocate an extension of the course to at least four years, the universal adoption of the metric system, and a bridging of the gulf between industry and academic institutions At the annual dinner, when the Lord Mayor of Liverpool spoke of the city's long association with chemical industry, anxious reference was once again made to the lapse of the Dyestuffs Act: the speaker on this occasion was Mr. C. S. Garland, who feared injury not only to the industry but also to the profession of chemistry. Dr E. F. Armstrong declared that Europe is going through a crisis equalled only by that which resulted from the Napoleonic wars. Great Britain has not yet adjusted herself to the new conditions. As a result of the War we shall have to adopt the policy, adopted by other countries, of being self-contained and self-sufficient. The future of Great Britain, and indeed of the world, he said, is in the hands of the chemist: the chemist cannot and must not fail, for the price of failure in the modern world is death.

THE twenty-eighth annual report of the Imperial Cancer Research Fund contains an interesting summary of the year's work; full accounts will appear in the Ninth Scientific Report, which is to be issued immediately. A good deal of energy has, naturally, gone to the study of the tumours of fowls which can be transmitted from one bird to another without the intervention of living cells, and three distinct histological types of tumour of this sort are under investigation. The possibility of transmitting mammalian tumours by cell-free preparations has been re-examined in the light of the experience with bird tumours, without finding any certain evidence that living cells can ever be dispensed with. The question whether one tumour renders an animal resistant to the development of a second tumour still remains unsettled. A careful examination by modern methods of the innervation of the skin and of tumours developing therefrom in the mouse has failed to confirm the suggestion that tumours have nerves of their own, though it is of course possible that this may sometimes occur. Chromosome studies of tumour cells have also been resumed, partly from the point of view that irregular distribution during mitosis may underlie some of the abnormalities of cancer cells, and partly with the ideas of heritable changes in genes which a contemplation of the fixity of type of any one tumour throughout its history must suggest. The whole report gives an encouraging account of the solid, steady progress made by Dr. J. A. Murray and his colleagues.

AMONG the foreign men of science who either visited or settled in England during the eighteenth century, few were better known than Jan Ingenhousz, whose trough for comparing the thermal conductivities of metal rods has figured in innumerable textbooks. Ingenhousz, who was born on Dec. 8, 1730, two hundred years ago, was Dutch by birth and a doctor by profession, and it was his desire to acquaint himself with the method of inoculation for smallpox which first brought him to England. From England he went to Vienna to inoculate the Austrian Royal family, and then travelled in Italy, France, and Germany. Returning to England in 1779, he spent the remainder of his life in the congenial society of his scientific friends, enjoying, as he said, "that felicity which a free and independent man finds in the pursuit of knowledge and wisdom, in the society and friendly intercourse of those who have distinguished themselves by learning". A friend and correspondent of many, he was elected a fellow of the Royal Society, twice delivered the Bakerian lecture, and wrote on electricity, chemistry, magnetism, and other subjects. Ingenhousz died at Bowood, the seat of the Marquis of Lansdowne, on Sept. 7, 1799.

ON Dec. 7 occurs the centenary of the birth of the eminent Italian mathematician, Luigi Cremona. Born and educated at Pavia, Cremona in his eighteenth year joined the Italian volunteers, during the rising against the Austrians, and was present at the defence of Venice. Resuming his studies, he graduated at Pavia, where Brioschi was among his teachers, and afterwards taught mathematics at Cremona and Milan. In 1860 he became professor of higher geometry in the University of Bologna, in 1866 was transferred to Milan, and in 1873 became professor in the University of Rome and director of the School for Engineers. During thirty years of arduous work he reorganised the whole mathematical instruction of Italy, and was as ardent a politician as man of science. His writings include his "Graphic Statics", translated into English by Sir Hudson Beare, his "Introduction to a Geometrical Theory of Plan Curves", and "Elements of Projective Geometry". He became a Senator of Italy in 1879, and in 1898 was made Minister of Public Education. A member of many scientific societies, including the Paris Academy of Sciences and the Royal Society, he was well known among British mathematicians. He attended the tercentenary celebrations of the University of Edinburgh, and was the guest of Chrystal, who, in a note appended to an obituary of Cremona and referred to in NATURE of Aug. 27, 1903, p. 392, recalled the dinner given by Lord McLaren, when seated around the table were Cremona, Hermite, Picard, Helmholtz, Cayley, Sylvester, Kelvin, Stokes, Salmon, and Rayleigh.

MR. J. BRADLEY, Wallasey Grammar School, Cheshire, referring to the review by Prof. H. Dingle in NATURE of Nov. 22 of Sir James Jeans's 'The

Mysterious Universe", sends us the following apposite quotation from an address by Ernst Mach, delivered at the anniversary meeting of the Imperial Academy of Sciences, at Vienna, on May 25, 1882, entitled, "The Economical Nature of Physical Enquiry" ("Popular Scientific Lectures", by Ernst Mach. Open Court Publishing Company): "What those ideas are with which we shall comprehend the world when the closed circuit of physical and psychological facts shall lie complete before us, (that circuit of which we now see only two disjoined parts), cannot be foreseen at the outset of the work. The men will be found who will see what is right and will have the courage, instead of wandering in the intricate paths of logical and historical accident, to enter on the straight ways to the heights from which the mighty stream of facts can be surveyed. Whether the notion which we now call matter will continue to have a scientific significance beyond the crude purposes of common life, we do not know. But we certainly shall wonder how colours and tones which were such innermost parts of us could suddenly get lost in our physical world of atoms; how we could be suddenly surprised that something which outside us simply clicked and beat, in our heads should make light and music; and how we could ask whether matter can feel, that is to say, whether a mental symbol for a group of sensations can feel?"

MR. HERBERT MORRISON, Minister of Transport, proposing the toast of the Institution of Professional Civil Servants at the annual dinner on Nov. 27, paid an encouraging tribute to the work of the technical and professional people engaged in various departments of the Civil Service. These include research workers and observers of many types; civil, electrical, mechanical, naval, and aeronautical engineers; surveyors, architects, valuers, medical men, and others with professional qualifications carrying on the work of the State. Mr. Morrison said he has "a special affection for the technical and professional officers in the public service", and he appreciates their readiness "to make their political chiefs understand the technical effects of the problems with which they have to deal". The difficulty in the past has often been for an officer in charge of a scientific or technical department to have direct access to a Minister, but we believe this condition of things is changing, and Mr. Morrison is evidently desirous himself of being provided with as full knowledge as possible of the technical aspects of problems which it is his duty to champion in the public arena.

SIR RICHARD REDMAYNE, in responding to the toast of the Institution of Professional Civil Servants, referred to the importance of the problem of transport in connexion with the distribution of everyday commodities and the aid which scientific men and technologists can give the administrator in solving it. He said: "In my view, what is required to be done is to mobilise more fully, in the interests of the community, the scientific knowledge and the technical experience possessed by such classes as those who form the membership of the Institution. The difficulties in which we as a nation now find ourselves are not, if Mr. Morrison will allow me to say so, entirely soluble by political methods. When all is said, the expert, and under this term I, of course, include the scientist, is largely the architect of modern civilisation and should be given a status in the community worthy of his attainments. If the Royal Commission, now sitting, do nothing more than recognise this fundamental truth and make the necessary recommendations in regard to the Civil Service, we, in the Institution, would be well content with our efforts in that direction".

FOR the third time since the great disaster of 1923, Japan has been visited by a destructive earthquake. The Tazima earthquake of May 23, 1925, and the Tango earthquake of Mar. 7, 1927, both on the Japan Sea side of the Main Island, were responsible for the losses of 428 and 3017 lives respectively. The centre of activity has now returned to the Pacific coast, and at 4.3 A.M. on Nov. 26 (7.3 P.M. on Nov. 25, G.M.T.) a severe earthquake caused much loss of life and property in the Izu peninsula and on the west side of Suruga Bay. According to the official estimate of the following day, 245 persons were killed, the towns that suffered most being Shizuoken and Mishima, while great damage is reported at Numazu, Hakone, and other places in the Izu peninsula. The shock was felt as far as Fukui, about 170 miles from the epicentre, which, according to Prof. Imamura, is believed to be slightly to the east of the centre of the peninsula. It was recorded at Kew at 7 h. 15 m. 40 s. P.M. on Nov. 25, but the movement there was less than that on Mar. 7, 1927, or even on Aug. 5, 1927, and May 27, 1928. The Izu peninsula, which lies between the two deep depressions of Sagami Bay and Suruga Bay, has felt at least ten destructive earthquakes since the beginning of the Japanese seismic record in 416. Its eastern coast near Ito was the seat of 3684 slight shocks in the spring of the present year (NATURE, Aug. 30, 1930, vol. 126, p. 326). It is perhaps worthy of notice that, while the epicentre of the Tango earthquake lies 11 miles to the east of that of the Tazima earthquake, the epicentre of the recent shock is only a few miles to the west of that of the great Kwanto earthquake of 1923.

IT seems now to be quite satisfactorily settled that Louis Aimé Augustin Le Prince was actually the first to make cinematograph pictures and to show them by methods and apparatus strictly comparable with those in common use to-day. Le Prince was born at Metz in 1842, but he lived for about nineteen years in Leeds and five years in the United States. He was last seen entering a train for Paris on Sept. 16, 1890. From then, he and his luggage and papers disappeared completely, and exhaustive inquiries have never led to any clue being discovered. In 1886 he applied for an American patent, and in January 1888 for a British patent, which included punched holes fitting on the pins of the guide rollers. In 1888 he took pictures at the rate of 12 and at 20 a second, in Leeds, and showed them successfully. A memorial tablet to Le Prince will be unveiled by the Lord

Mayor of Leeds on Dec. 9, on the site of his workshop. It is also proposed, if sufficient funds are available, to publish a pamphlet giving full details of Le Prince's work in cinematography, and also that of other pioneers. There is already a considerable list of subscribers, but more funds are needed. Cheques or postal orders made payable to "Le Prince Memorial", and crossed "Midland Bank, Leeds", may be sent to the hon. treasurer, Mr. John H. Horsman, 31 Wesley Road, Armley, Leeds, or to the hon. secretary, Mr. E. Kilburn Scott, Conway Hall, Red Lion Square, London, W.C.1.

THE annual general meeting of the Newcomen Society was held at Caxton Hall on Nov. 27, when Mr. C. E. Greener was elected president in succession to Mr. L. St. L. Pendred. There are 259 individual members and 58 institutions now on the roll of the Society, of which 67 members and 25 institutions are in the United States. Seven papers were read during the session 1929–30; during the summer meeting at Liverpool the Society took part in the centenary celebrations of the Liverpool and Manchester Railway, and it was also represented at the jubilee meeting of the American Society of Mechanical Engineers and at the unveiling of the monument erected to mark the site of the Allegheny Portage Railroad constructed in 1834 to link together the eastern and western division of the canal system from Harrisburg to Pittsburg. Through the Council, the Society has given its adhesion to the International Congress of the History of Science and Technology to be held in London in June–July 1931.

AT the same meeting on Nov. 27 of the Newcomen Society, Mr. Rhys Jenkins read a paper on "Fire-extinguishing Engines in England, 1625–1725", the former year being that in which a patent was granted to Roger Jones by James I., and the latter being the year of Newsham's second patent. At Roger Jones's request, the patent was issued in the name of his brother John, a London merchant, who in his travels abroad had found out the plan of making a portable pumping apparatus. With the aid of the invention, so the patent ran, ten men could quench a fire with more ease than five hundred men with buckets and ladders, and its value had been shown on the occasion "of a fire latelie happened in the dwelling house of James Demetrius, Brewer in St. Katherines neare the Tower of London". Illustrating his remarks by means of the writings of Besson, 1587; Lucar, 1590; Zeising, 1612–14; de Caus, 1615; Bate, 1634; Fuller, 1662; and others, Mr. Jenkins gave a sketch of the development of the hand fire-engine, which reached a certain degree of perfection by the efforts of Richard Newsham, of Cloth Fair, London, engineer, one of whose engines can be seen in the Science Museum. It was remarked of Newsham by a writer in the *London Magazine* for 1752 that in his engines he gave "a nobler present to his country than if he had added provinces to Great Britain". These early fire pumps could throw a jet of water a considerable height, but their usefulness always depended on the rapidity with which water could be conveyed to them, which was generally done with buckets.

ACCORDING to a dispatch from its Beirut correspondent which appears in the *Times* of Nov. 27, a chair in archæology has been founded in the American University of Beirut through the munificence of a Syrian woman who wishes to remain unknown. The first occupant of the chair will be Dr. Ingholdt, the Danish archæologist, the appointment in the first instance being for a period of five years. Under the terms of his appointment, Dr. Ingholdt will lecture during one semester in each year and will spend the second semester in excavation at Hama, on the Orontes, on behalf of the Carlsberg Foundation. Dr. Ingholdt, who is a gold medallist of the University of Copenhagen, is an authority on Aramaic inscriptions and papyri of pre-Christian times and on Aramaic dialects. His discoveries of a few years ago in Palmyrene tombs attracted no little attention at the time. Although archæological studies have been actively prosecuted in Beirut for some time past, especially by the French Fathers of the Université de St. Joseph, who publish a journal of much interest to students of early Syrian culture, the facilities for instruction and training which will now be available in Syria itself will prove without doubt of great assistance in the advancement of such studies in an area which, notwithstanding its interest, has scarcely received adequate attention.

AT a meeting of the Optical Society, on Nov. 13, Mr. D. M. Smith, of the British Non-ferrous Metals Research Association, demonstrated the use of the spectrograph in metallurgical analysis. Messrs. H. Buckley and F. J. C. Brookes, of the Photometry Department, National Physical Laboratory, showed a new type of spectrophotometer in which there are no moving optical media. Two light sources, consisting of gas-filled tungsten lamps each behind ground glass, are used. The ground glasses are used as secondary light sources of high uniform brightness (up to 400 candles per square inch). The photometric scale of the instrument is in terms of the voltage intensity relation of one of the light sources at a standard wave-length in conjunction with rotating sector discs of known transmission. The voltage intensity relation at other wave-lengths is deducible from that at the standard wave-length by simple computation. Special provision is made whereby the wave-length scale of the instrument is not affected by mechanical alteration in slit width. The Maxwellian method of view is utilised. The precision of the instrument is high, the average deviation from the mean of determinations of spectral transmission throughout most of the spectrum being about 0·5 per cent.

EXCELLENT and novel methods of lighting streets and buildings have recently made rapid progress in many towns in Germany. When electric light was first used, the main object was efficiency. The sole object of the lamps was to give light. Then came the time when old chandeliers, lanterns, and brackets were introduced, some of which were good and others very bad reproductions of 'period forms' with electric bulbs instead of candles. Now, especially in Germany, the designers of illuminating fittings have

recognised that the shapes of the lamps can be made interesting and decorative. In a series of papers on modern lighting, the first of which appeared in the *Electrical Review* for Oct. 24, A. B. Read gives many illustrations of the modern methods of lighting used by German electricians. He compares the lighting of the dining-rooms in our giant liners with the decorative lighting of the new North German Lloyd *Bremen*. British shipping companies still adhere to 'period' decoration similar to that used in many large hotels. In the *Bremen* the lighting forms a prominent decorative feature. The continuous alabaster lighting of the first class dining-hall and the huge ceiling fitting in the ballroom are admirably designed. Neat tubular wall brackets, corner lights, large decorative fixtures, and even the small bunk lights all show a breaking away from tradition. In London we see too often shops competing with their neighbours by means of projecting signs and flickering lights of every conceivable kind. There are also in some places huge signs with colossal letters straddling over windows and other architectural features and quite spoiling well proportioned buildings. In many towns on the Continent the names over the shops are made luminous at night and a high standard of lettering is used. The orderliness of the signs adds dignity to the streets and is very impressive.

THE Astor expedition to the Galapagos Islands, an account of which appears in the August number of the *Bulletin* of the New York Zoological Society, is the latest of several recent expeditions to this wonderful group. The explorers reached farther inland on Indefatigable Island than former travellers and attained a height of 2100 feet, but the main observations have to do with the fauna of the islands, which is distinctive. The islands boast two flightless sea-birds, the Galapagos penguin and a flightless cormorant (*Nannopterum harrisi*), a species which is gradually disappearing. The same fate hangs over many of the inhabitants the great tortoises, the land iguana, the peculiar fur seal (*Arctocephalus philippi*), and others. This is due partly to the use made of some for food and oil, and partly to the introduction on some of the islands of pigs, dogs, cats, and rats, all of which are now abundant in a wild state, and have seriously affected the native fauna. The recommendations are made that all surviving species of tortoises, as well as the penguin and flightless cormorant, should be protected; that sealing should be prohibited; that the land iguana should be introduced to such islands as are free from pigs and dogs; and that pests should be destroyed. It is wise advice (notwithstanding that it so often comes from an expedition which has freely satisfied its own needs), and it would be well for science if the Ecuadorian Government could be convinced of its necessity and supported in carrying it out.

AN excellent photograph of a school of the false killer whale (*Pseudorca crassidens*) stranded near Kayts, Ceylon, in 1929, appears in the Report of the Colombo Museum for that year. Extraordinary interest attaches to this occurrence, following upon the strandings of large numbers, first in the Dornoch Firth in Scotland and later near Cape Town, of a species regarded as on the verge of extinction. It is strange, therefore, that the only reference in the text of the Report to the stranding of the false killers is a bare record—not even mentioning the numbers of whales observed—of the preparation of 12 skulls and 2 complete skeletons. The Museum itself becomes more and more appreciated, judging by the increase in the number of visitors (now about 800,000 a year) and the greater use made of the collections by teachers and school classes. A new wing is now being built to relieve congestion amongst the exhibits.

AT a general meeting of the members of the Royal Institution held on Dec. 1, Lord Eustace Percy was elected president of the Institution in succession to the late Duke of Northumberland. Lord Eustace, who is a younger brother of the late Duke, was president of the Board of Education in 1924–29 and this year is president of Section L (Educational Science) of the British Association.

AN international celebration and exhibition to mark the three-hundredth anniversary of the first recognised use of cinchona by Europeans will be held at the Wellcome Historical Medical Museum, 54 Wigmore Street, Cavendish Square, London, W.1, on Dec. 8 and 10. Addresses will be given by the Marquis de Merry del Val, Ambassador for Spain; Archbishop Goodier, formerly Archbishop of Bombay; Sir David Prain, formerly Director of the Royal Botanic Gardens, Kew, and Sir Humphry Rolleston, Regius professor of physic in the University of Cambridge. An extensive collection of exhibits has been arranged to illustrate the history of cinchona, the addition of which to the world's materia medica has, for three hundred years, proved itself to be of incalculable value, especially in tropical regions. An article on the history of cinchona and its introduction to India and other countries appeared in NATURE of Nov. 29, p. 850.

THE annual Congress and Exhibition of the British Institute of Radiology was held at the Central Hall, Westminster, on Dec. 3–5. The Mackenzie Davidson Medal of the Institute was awarded to Prof. G. P. Thomson, of the Imperial College of Science and Technology, and the Silvanus Thompson Medal to Dr. A. E. Barclay, lecturer in medical radiology and electrology in the University of Cambridge, who delivered the respective memorial lectures during the Congress.

DR. BRONISLAW MALINOWSKI, professor of anthropology in the University of London (London School of Economics), has been awarded the Rivers Memorial Medal of the Royal Anthropological Institute, in recognition of his distinguished field work in anthropology. Prof. Malinowski, who graduated at Cracow, did research work at the British Museum and the London School of Economics from 1910 onwards, went with the Robert Mond Anthropological Expedition to New Guinea and North-west Melanesia in 1914, returning to Australia in 1918 and to Europe in 1920. Among his numerous publications may be

mentioned "The Family among the Australian Aborigines", "Argonauts of the Eastern Pacific", "Crime and Custom in Savage Society", "Sex and Repression in Savage Society", and "The Sexual Life of Savages in North-west Melanesia".

THE Royal Anthropological Institute has created a class of associates with the object of bringing its facilities for study and research within the reach of the younger workers in anthropological subjects. Associates must be less than twenty-six years of age, they will pay an annual subscription of one guinea only, will receive the Institute's monthly publication (*Man*), and will have access to the library and ordinary meetings.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned: A graduate in engineering at the Oxford City Technical School and Municipal Secondary School—The Principal, City Technical School, Oxford (Dec. 8). A chief assistant in the Physico-therapy Department of St. Thomas's Hospital—The Secretary, St. Thomas's Hospital, S.E.1 (Dec. 9). A principal of the Constantine Technical College, Middlesbrough—The Director of Education, Education Offices, Middlesbrough (Dec. 13). A full-time teacher in the Department of Chemistry of West Ham Municipal College—The Principal, West Ham Municipal College, Romford Road, Stratford, E.15 (Dec. 13). An assistant bacteriologist and pathologist, an assistant and a junior assistant, each in the Bacteriological and Pathological Laboratory of the Staffs County Council—The Clerk of the County Council, County Buildings, Stafford (Dec. 13). A pathologist at the Royal Devon and Exeter Hospital, Exeter—The Secretary and Manager, Royal Devon and Exeter Hospital, Exeter (Dec. 31). An assistant in the Natural History Department of the Royal Scottish Museum—The Director, Royal Scottish Museum, Edinburgh (Jan. 17). An instructor for evening classes in engineering drawing at the Kingston-upon-Thames Technical College and School of Art—The Principal, Technical College and School of Art, Kingston-upon-Thames.

Our Astronomical Column.

Ancient Eclipses in Scotland. Mr. L. MacLellan Mann writes with reference to his claim of having identified a record on stone of the eclipse of B.C. 2983 Mar. 28 (see NATURE, Nov. 8, p. 743). As regards the time of day at which the eclipse occurred, he notes that the 0·6 day (about 2.30 P.M. Greenwich) found by the writer of the note in NATURE, is in good agreement with the value 0·63 found by C. Schoch, and with the value 0·66 which Mr. Mann obtains from the record on the stone; he notes that this may be the end of the eclipse. He states that he obtained the year by his interpretation of the system of wheel-like markings on the stone, which he takes to be cycles of years.

Referring to the cycle of 1805 years, Mr. Mann claims that this was probably known in ancient times; M. Oppert, the discoverer of the cycle, made a similar claim, but most astronomers hesitated to accept it. Mr. Mann makes an evident mistake when he speaks of the related cycle of 100 saroses: there is no such cycle—the greatest possible number of returns of an eclipse in the saros cycle is about 84; further, the eclipses at the beginning of a series would be visible in regions near one of the terrestrial poles, while those at the end would be visible near the opposite pole. Some thirty returns, or not many more, would suffice to carry the region of visibility away from a given latitude. Mr. Mann states that his investigations of these old stone records have occupied him for some twenty-five years, and he promises to make his results accessible to students at an early date.

Light-variation of Eros.—A note from Leningrad in *Astr. Nach.*, No. 5748, dated at the end of October, notes that M. Zessewitsch detected a light-variation in Eros with an amplitude of 1 magnitude and a period of 0·105 days, or $2^h\ 31^m$. In February 1901 a light-range of a magnitude was also noted, but the period was then given as $5^h\ 16^m$, slightly more than twice the period now announced. The $5^h\ 16^m$ period, however, included two unequal maxima, so that the period now found may be half the complete period. The variation was noticed in 1903, but appeared to be absent in 1907. The study of the light-variation is a suitable one for amateurs to undertake. The attention of the large observatories will be chiefly taken up in photographs for position, for the deduction of the solar parallax and the mass of the moon.

The Kepler Tercentenary. It is noted in *Astr. Nachr.*, No. 5744, that at the celebrations in memory of the death of Kepler that took place at Regensburg on Sept. 24 and 25, two minor planets were given names that would commemorate the event. Planet 927, discovered in 1920, was named *Ratisbona*; while planet 1134, discovered last year, was named *Kepler*. Both these planets were found at Konigstuhl by Prof. M. Wolf. The use of a masculine name for 1134 is justified by its small perihelion distance; the usual rule is that the names should be feminine, but exceptions are made in the case of the Trojans, and those (like Eros) that come fairly near the earth.

Astronomical Equipment.—The new catalogue of astronomical instruments and observatory equipment issued by Messrs. Cooke, Troughton and Simms, Ltd., is a beautifully illustrated volume which will be of interest to all concerned with observational work in astronomy, whether they are in need of additional facilities or not. The catalogue includes four main sections, dealing respectively with object glasses and general telescopic accessories, telescope mountings, transit instruments, and observatory domes, each of which is prefaced by a short note on the general subject of the section. These notes—particularly the first, on the adjustment, care, and use of telescope objectives—will be found very valuable by the working astronomer of limited experience. The telescopic accessories which are described are, in addition to eyepieces, mainly photographic, spectroscopic, and micrometrical. The spectroscopic instruments mentioned are not numerous, but a note of general application in the introduction states that although the catalogue includes only instruments of general interest and use, others required to meet special and unusual needs can also be supplied. The fine quality of the work produced by this firm and its predecessors is well known, and a historical note at the beginning of the catalogue reminds the reader of the original work of the separate firms of Troughton, Simms and Cooke, photographs of some of the more important instruments of which are given.

Research Items.

The Greenland Shaman.—Dr. William Thalbitzer records in the *Journal des Américanistes*, N.S., vol. 22, fasc. 1, observations on the character of the shaman and his beliefs relating to the world and the soul, made at Ammassalik, the most northerly settlement on the eastern coast of Greenland. Near the settlement were about 500 pagan Eskimo, living in villages. Each group had its shaman (*angakkok*). These had no temporal power but considerable moral and religious authority. The shaman gave spirit manifestations almost nightly in one of the houses by the light of a single lamp, all other lights being extinguished. He conversed with the spirits in a sacred and mystical language, consisting of archaic words not fully understood by the spectators. Only the elect became shamans—dreamers and visionaries of an hysterical temperament. They were selected by the shaman to become his pupils and receive instruction in the mountains. The course of instruction lasted for from five to ten years, and the pupil received instruction not from one alone but from several shamans. In the course of instruction the pupil was devoured by the spirit of a bear but came to life again; he entered into communion with the spirits of the dead, spirits of metamorphosed animals, and the spirits of the other world. When he had learned from these their names, they became his allies and he could summon them to do his bidding. When he had thus become the master of all knowledge, he took up the functions of a shaman, one of these being the power of inflicting evil on a man's enemies or protecting him from their attacks. Each shaman had from ten to fifteen allied spirits. The shamans were thoroughly sincere in their belief in their powers and the manifestations of the spirits.

The Monozoic Cestode *Archigetes*.—L. W. Wiśniewski, in *Mem. Acad. Polonaise Sci. et Lettres*, Series B, Sci. Nat., vol. 2, 1930, gives an account of the anatomy, biology, and systematics of the cestode genus *Archigetes*, three species of which were studied. The adult *Archigetes* is regarded as a neotenic procercoid and this is the final stage of the life-history. The host, an aquatic oligochaete—for example, some species of *Limnodrilus* or of *Tubifex*—becomes infected by swallowing the egg containing a fully developed oncosphere which is not ciliated or free-swimming. The oncosphere issues from the operculate egg in the intestine of the host, penetrates the gut-wall, and lies in the body cavity, where it grows to sexual maturity, causing a swelling of the body and eventually a rupture of the body wall so that the parasite escapes to the exterior. Its tissues decompose and the eggs fall into the mud. The oncosphere, which has three pairs of hooks—a larger median and two lateral pairs—develops in about 40 days and may live enclosed in the egg-shell for 70-80 days. The egg-shell is formed from the secretion of the yolk-cells. In the young stages the cells of the developing oncosphere lie loose, there is no epithelium; the cells are surrounded by a membrane. The author describes the anatomy and histology of the adult worm. An account of the early stages of *Archigetes* is given by I. Motomura in *Annot. Zool. Japon.*, vol. 12, 1929, who states that the development so far as the oncosphere is carried on in the uterus of the parent.

Demanian Vessels in Nematodes.—N. A. Cobb (*Jour. Washington Acad. Sci.*, June 1930) describes in nematodes of the genus *Oncholaimus* a remarkable system of vessels which he terms the demanian vessels—after de Man, who first discovered these tubular organs. The complicated double system of vessels is connected with the middle or posterior part of the intestine and with the uterus. The two ducts are confluent and discharge their contents through pores in the body wall near the base of the tail. The vessels are not present in young females; they come into existence at the last moult. In adult females the vessels elaborate a copious sticky secretion, insoluble in water; and the author, after examining the possible functions of this material, suggests that it is utilised during agglomeration and copulation, and also presumably to protect and preserve the batches of eggs after deposition. The demanian organs seem to occur in mud-inhabiting Oncholaims, that is those of stagnant habit, and to be absent in those which live in more thoroughly oxygenated water.

Habits and Development of the Synentognathi.—Mr. C. M. Breeder's notes on the fishes belonging to the families Belonidæ and Exocœtidæ from the Dry Tortugas are very interesting (Year Book 28, Carnegie Institution of Washington, pp. 279-282). The young of the four species of *Strongylura* are highly differentiated and specialised in various ways, the proportional development of the beak proceeding in decidedly different directions in each. The post-larvæ here are almost entirely confined to the drifting *Sargassum*. Older, but still young, fish occur in schools, usually of one species and of one size, and stay close to the shores, circulating about so that a given school may appear every two or three hours at a given place, in the meantime being replaced by other schools of different species or of different-sized individuals. Three species belonging to the Exocœtidæ were specially studied, *Parexocœtus mesogaster* being much the most abundant. Its young, of only a few millimetres in length, when the wings are too short for flight, so closely resemble their parents as to be recognisable at sight with their simple blue and silver colouring. These occupy the clear spaces between the drifts of *Sargassum*. On the other hand, the young of *Cypselurus fuscatus* are markedly different from their parents and show a series of patterns and colour changes which resemble the floating *Sargassum* and debris in which they are found. Associated with the habitat is a difference in the possession of barbels in the young *Cypselurus* and not in *Parexocœtus*. The barbels seem to be used in poking about in the weed. The Exocœtids, especially the young, are found to be very important as food for other fishes and for sea-birds.

Types of Gabb's Californian Fossil Pelecypods.—R. B. Stewart's revision and rectification of Gabb's work on the Cretaceous and Tertiary fossils of California (published in 1864 and 1869 by the California Geological Survey) has now been completed by the issue of the part relating to the Pelecypoda or Lamellibranchia (*Acad. Nat. Sci. Philad.*: Special Publication, No. 3). The first part, relating to the Gastropoda, appeared in 1926 and attention was directed to it in NATURE of Feb. 12, 1927, p. 255, and the lines on which the reviser proceeded were then indicated. The same methods have been adopted in the present part, with some amplification of the information concerning the strata containing the fossils, but as a whole it is of far greater importance to systematists generally. For the first time, we believe, in an American work of this importance, Pelseneer's classification of the group Pelecypoda, as set forth in Lankester's "Treatise on Zoology" (vol. 5), has been employed in lieu of Dall's; whilst in the matter of nomenclature, the International Rules of Zoological Nomenclature have been applied even when opposed to the revisor's own ideas, and the need for teaching students of palæontology the rudiments of those rules pointed out. To all this has gone

an immense amount of research work, which has been most thoroughly and carefully carried out, to the great benefit of all subsequent investigators, although doubtless some *emendanda* will reveal themselves as time goes on. Certain new names have had to be created: thus there are seven new genera and twenty-five new subgenera proposed, some of the latter being for the reception of old friends. The illustrations on the 17 plates are, as before, from photographs taken and retouched by Miss Helen Wichester: and excellent they are. Some additions and corrections to the part on the gastropods have been appended to the introductory chapters, while an "Index to Genera and West Coast Species and to Genera of the paper on the Gastropods" concludes this indispensable work.

Flora of Yucatan.—This work by P. C. Standley (*Field Museum of Nat. Hist.*, Chicago. Bot. Series, vol. 3, No. 3; 1930) treats of the Mexican portion of the Yucatan Peninsula. The whole area of 55,000 sq. miles is low-lying and composed of a sheet of porous and friable limestone rock with a striking absence of permanent surface streams. In the dry region of the northern plains there are few large trees, and where not under cultivation the land is covered with scrub, a few cacti being plentiful, with occasional palms. The central undulating part of the Peninsula, which has a heavier rainfall, has extensive low forests, whilst the forests of Campeche and Quintana Roo yield many valuable woods and other produce, including logwood, mahogany, cacao, sarsaparilla, and rubber. The sharply differentiated geological and physiographical features of Yucatan are reflected in the flora, which is radically different from that of other parts of Mexico and Central America. Its proximity to Cuba and similarity in geological conditions account for the many plants common to both countries. The number of native plants listed comprises 557 genera and 1068 species, the best represented families being the Leguminosæ (119 sp.), Compositæ (86 sp.), Euphorbiaceæ (69 sp.), and Gramineæ (68 sp.). The degree of endemism is notably high for a continental area, embracing 17 per cent of the native flora. Of the Euphorbias 39 per cent are endemic, whilst three genera of the Rubiaceæ and Compositæ are confined to the Peninsula. The species enumerated include naturalised and cultivated plants, whilst an account is given of botanical exploration of the Peninsula—far from complete—together with a list of vernacular names and a bibliography.

Pre-Cambrian Formations of Western Australia.—The Annual Progress Report of the Geological Survey of Western Australia for 1929 is notable in containing a valuable summary of the present state of knowledge of the Pre-Cambrian rocks of that terrain, accompanied by a clearly drawn geological map. The Yilgarn Series are predominantly of sedimentary parentage; they are invaded by greenstones which in turn are followed by granites. In the Kalgoorlie Series, greenstones with intermediate and acid lavas and pyroclasts are the characteristic members. A later series of metamorphosed basic and ultrabasic rocks, known as the "younger greenstones", invades the "older greenstones". The Mosquito Creek Series has been regarded as younger than the Kalgoorlie greenstones. It consists in the main of sediments that are less profoundly metamorphosed than those of the Yilgarn Series. The Government Geologist, Mr. Blatchford, however, thinks that some of the rocks mapped as Mosquito Creek may be Yilgarn or Kalgoorlie, while others may even be Nullagine. The Nullagine Series is not yet definitely known to be Pre-Cambrian, in the Kimberley district; it may be Lower Cambrian. A large part of the State is shown as consisting of granites and gneisses. It is probable that these are of several ages. The goldfields granites cut the Yilgarn, Kalgoorlie, and Mosquito Creek series, but the marginal gneisses are themselves cut by dykes which are indistinguishable from those of Kalgoorlie age.

Relations between Sunspot and Earthquake Frequency.—Messrs. T. Takayama and T. Suzuki have studied the relations between sunspot activity and the frequency of destructive earthquakes in Japan (*Earthq. Res. Inst. Bull.*, vol. 8, pp. 364-374; 1930). In the whole Japanese area they are unable to detect any relation, but considering Omori's three seismic zones separately, they find that, in the inner or Japan Sea zone, destructive earthquakes are more frequent near the sunspot maxima, in the outer or Pacific zone near the sunspot minima, while in the inland zone between them there is no definite relation.

Surface Drift Currents in the North Sea. Mr. J. B. Tait, in "Surface Water Drift in the Northern and Middle Areas of the North Sea and in the Faroe-Shetland Channel" (*Fisheries, Scotland, Sci. Invest.*, 1930, No. 2), reports upon the drift of 4825 bottles which were liberated in batches from numerous widespread points in order to determine the drift of surface waters in this area during each of the five years 1910-14. Of these bottles, weighted to float just awash, 1096 were recovered, mostly stranded on the east coast of Britain and on the shores of the Continent between Texel and the North Cape. The results suggest that more water from the Atlantic enters the North Sea between Shetland and Norway than through the channels between Shetland and the mainland of Scotland, and indicate that almost two-thirds of the distance between Shetland and Norway is occupied by water moving southward into the North Sea. A stream of surface water from the Atlantic in the direction of the channel between the Shetlands and Orkneys appears to have its progress barred on occasions by a north-flowing surface current from the Moray Firth to Shetland, causing the former stream to divide, part turning north to flow west of the Shetlands and part turning south between Fair Isle and Orkney. The results also suggest that the general current system in the northern part of the North Sea is subject to irregularities. The author mentions the lack of close correlation between the drift of these bottles and wind, such as is met with in the southern part of the North Sea and in the English Channel.

Map Revision by Air Photographs.—With the view of investigating the value of air photography compared with ground work in the revision of large scale maps, the Ordinance Survey chose an area near Brighton to be photographed on a scale of about 1 to 7500 with a 50 per cent overlap in consecutive negatives. The photographs were compared with corresponding field traces which were marked to show where alterations had occurred. Revisers then visited these places and put in the detail by the usual ground methods. Three types of country were included in the experimental area, open down, suburban districts with much new building, and closely built town. The results are summarised in a leaflet of the Ordinance Survey (Report on the Experimental Revision of the 1/2500 Ordinance Survey Plans with the aid of Photographs taken from the Air, No. 2, 1928-30). The method was found to be uneconomical in open down lands and in suburban areas of rapid growth. On the other hand, in closely built areas it effects substantial economies compared with ground work, although the completeness of the revision is liable to suffer since certain features are

missed, notably wire fences and internal divisions between houses. These would have to be put in by ground work if required.

Flashing Afterglow in Discharge Tube.—Mr. V. Dumert, 22 Fortis Green Road, East Finchley, sends us a letter describing flashing phenomena in a discharge tube similar to those described by Mr. Braddick in NATURE of Nov. 8, p. 725. The discharge tube was a burnt-out carbon filament lamp, made presumably of soda glass since it showed green luminescence. A continuous afterglow was followed by an intermittent flashing when the glass of the lamp was touched. A valve amplifier, connected between the metal cup and an external electrode of copper foil, gave no sound during the continuous afterglow; then a rushing sound which stopped abruptly at each flash. The phenomenon suggests that the conditions in a discharge tube may be considerably affected by charges on the inside and outside of the glass walls. An effect which is doubtless due to such charges is sometimes observed with heavy discharges run through capillary tubes with moderate voltages; for example, the hydrogen discharge tubes used as a source of light in ultra-violet spectrum work. The tube refuses to run steadily unless an earthed coating of metal foil is closely wound about the capillary.

Emission of Radiation from Excited Surfaces. It is known, from the experiments of Prof. O. W. Richardson and others, that the inelastic reflection of an electron from a metal surface involves characteristically the transfer of a definite amount of energy from the electron to the surface. The surface appears to have quantised energy levels, and so it might be expected that an excited surface would emit radiations corresponding to transitions between pairs of these. A search for radiation of this type is described by Dr. E. Rudberg in the *Proceedings of the Royal Society* for November, a number of substances being bombarded which would be expected to emit line radiation from this effect in the visible or quartz ultra-violet regions. The experiments were entirely negative, the only lines obtained being attributable to impurities in the vacuum apparatus; and from a discussion of other results on the energy levels of the surfaces, Dr. Rudberg concludes that this result, which applies in the first instance only to the lower possible energy losses of the surfaces, is probably general, that is, that the rearrangement of the disturbed surface takes place without emission of radiation.

Ozone in the Earth's Atmosphere.—Dr. G. M. B. Dobson has contributed a paper to the November number of the *Proceedings of the Royal Society*, in which, after giving an account of further detailed observations on the ozone of the air, which conclude the original programme of work proposed five years ago, he summarises the results which have been obtained, and discusses the remaining outstanding problems. Dr. Dobson considers that the two fundamental points which need to be decided are, first, the nature of the agents forming and destroying the ozone, and secondly, the nature of the connexion between the ozone high in the atmosphere and the meteorological conditions much lower down. He expresses the opinion that the chief ozone-forming agent is the corpuscular radiation from the sun—including the action of electric fields which may be set up by this in the air—at least, near the poles, and possibly over the whole world; the destruction of ozone is attributed to the action of solar radiation of wave-lengths between 3300 A. and 2200 A., and to thermal decomposition, the amount of the latter being rather sensitive to the temperature. Dr. Dobson expresses no definite opinion on the second question, but gives, as the most probable ways in which a connexion could be brought about, transport of large masses of the atmosphere over the surface of the earth, transport by vertical currents, and actual formation and decomposition of ozone over the areas in question, all of which are, however, somewhat unlikely for one reason or another. Dr. Dobson hopes to conduct future work with photoelectric spectrophotometers, instead of the photographic instruments which have been used up to the present. It should be mentioned that two recent papers by Prof. S. Chapman (in the *Philosophical Magazine* and the *Memoirs of the Royal Meteorological Society*) in which the kinetic aspects of the reactions occurring in the upper air are examined, emphasise the need for fairly accurate knowledge of the temperatures involved, and that these are now believed to be higher than was previously supposed.

A New Methylation Process.—The difficulties encountered in the exhaustive methylation of hydroxyl groups in complex compounds are well known. Since the methylated products have often proved extremely useful in the elucidation of structural problems in the investigation of carbohydrates and many other natural compounds, it is of interest to learn that Dr. M. Nierenstein, of Bristol, has described a new process of methylation which consists in replacing acetyl groups by methyl groups with the aid of diazomethane in the cold. This reagent needs careful handling as it is extremely poisonous. In the *Journal of the American Chemical Society*, vol. 52, p. 4012, some preliminary results are recorded. The reaction takes place in the presence of piperidine, one molecular proportion of which is used for every acetyl group replaced. An ethereal solution of diazomethane prepared from nitrosomethylurethane by a method described in a previous paper in the same journal (vol. 52, p. 1508) is distilled into an alcoholic solution of the acetylated hydroxy-compound to which the requisite amount of piperidine has previously been added. After standing for 24 hours the alcohol is removed and the residue refluxed with aqueous alkali. The piperidine is then extracted with ether and the methylated product is liberated with acid. The method has been successfully applied to the preparation of veratric acid, isovanillic acid, dimethyl β-resorcylic acid, monomethyl β-resorcylic acid, and trimethyl gallic acid. Experiments on the methylation of penta-acetyl catechins, which by other methods give impure products, are in progress.

Atomic Weight of Rhenium.—Since the element rhenium is now being produced in Germany in considerable quantities, its atomic weight has been redetermined by O. Honigschmid and R. Sachtleben in the Atomic Weight Laboratory at Munich (*Zeit. anorg. und allgem. Chemie*, **191**, 309; 1930). The authors have studied the reaction of rhenium which appeared suitable for an atomic weight determination, and found that the preparation of metallic rhenium from the disulphide by heating in a stream of hydrogen did not take place quantitatively, so that the value for the atomic weight determined by W. and I. Noddack appeared doubtful. By heating rhenium metal in a stream of chlorine there was formed a rhenium chloride which could be sublimed but was apparently not homogeneous. The analysis of silver perrhenate ($AgReO_4$), by precipitating with hydrobromic acid and weighing the silver bromide, proved to be a suitable method. The methods used in the preparation and analysis of the pure silver perrhenate are described. From seven determinations it was found that 51·82860 gm. $AgReO_4$ gave 27·17309 gm. AgBr, from which was derived the relation: $AgReO_4 : AgBr = 1 \cdot 90735$, and the atomic weight of $186 \cdot 31 \pm 0 \cdot 02$ for rhenium.

Anniversary Meeting of the Royal Society.

SIR ERNEST RUTHERFORD completed his term of office as president of the Royal Society by a noteworthy address on the Society's policy for the promotion of research, before he presented the medals for 1930 at the anniversary meeting on Dec. 1.

Looking back over the years since the end of the War, Sir Ernest pointed out how the responsibilities and work of the Society have increased during that period. Between 1919 and 1923, the Society received bequests under the wills of Miss Agnes Foulerton, Dr. Rudolph Messel, and Dr. Ludwig Mond, and a notable benefaction from Sir Alfred Yarrow. Foulerton and Yarrow research professorships were in due course instituted, and regulations for the Messel and Mond funds were adopted, subject to periodical review, which provided for further professorships as the need and opportunity might arise.

The Council of the Royal Society has watched the effect of thus endowing research professorships and is satisfied that the experiment, in Sir Ernest's words, "has proved an unqualified success". The appointments have added materially to the strength of the research side of the universities where the Royal Society professors are working, and "have led to a marked increase in the research power of the nations". While it would be unwise to increase their number unduly in the near future, the Council has decided that the Messel and Mond funds can now be employed to the benefit of the whole body of science by supporting the work carried out in recent years by Dr. P. Kapitza, fellow of Trinity College, Cambridge, who has accordingly been appointed to a Messel professorship.

The funds held in trust by the Royal Society now amount to more than £600,000. Plans for the utilisation of the income from these funds have been carefully matured during the past ten years, for it was difficult to foresee the financial commitments of the Society due to its existing activities. The increased volume of publication after the War and the disproportionate increase of costs involved heavy expenditure, which the Council felt was justified in the interests of scientific research, but it has now been decided that the price of the Society's publications to outside subscribers must be increased. This will release a substantial sum which can be devoted to other purposes. It is now felt, however, that the time and opportunity have come to expend some of the accumulated income of the Society's trust funds, with the result that the sum of £15,000 has been offered to the University of Cambridge for the purpose of building a cryogenic laboratory for the continuance of Dr. Kapitza's researches on the magnetic properties of materials at very low temperatures. The circumstances of the offer and an outline of Dr. Kapitza's work are given in an extract from Sir Ernest Rutherford's address which appears elsewhere in this issue.

The Council's policy, Sir Ernest said, has been and will be to keep watch over the whole field of scientific activity, giving help where there is promise of important advances and where the right man is to hand. It is by the support of major fundamental researches, especially in their initial stages, that the Society can employ most effectively the research funds which it has at its disposal.

Sir Ernest Rutherford also referred to the institution of a new research fellowship, financed from the bequest of the late Mr. E. W. Smithson. The first award has been made to Dr. P. D. F. Murray. After a distinguished undergraduate career in the University of Sydney, Dr. Murray spent two years in research work in the Department of Comparative Anatomy at Oxford, and since 1926 has been lecturer in zoology at the University of Sydney. Nearly all his work has been in the field of experimental embryology, and he has investigated with conspicuous success the factors which determine the differentiation and shaping of the limbs and other parts of the body. Dr. Murray proposes to examine the cellular differentiation of the developing chick, which underlies the coarser morphology, and he will work in the first instance at the Strangeways Research Laboratory in Cambridge.

Sir Ernest Rutherford announced at the anniversary meeting that it has been decided to increase the number of candidates recommended annually for election to the Society from fifteen to seventeen. The Council reports that during the past year the Society received £8000 for general purposes under the will of Sir Dawson Williams and £500 for research under the will of Col. G. H. Leathem. In addition to the Messel research professorship and the Smithson research fellowship referred to above, the following research appointments were made during the past year, the subject of research being given in brackets: Foulerton Research Fellow, Dr. A. S. Parkes (physiology of reproduction); Mackinnon Research Student, Miss M. E. J. Chandler (fossil fruits and seeds of tertiary and quaternary age); Moseley Research Students, Mr. G. S. Adair (proteins of blood) and Dr. J. K. Roberts (exchange of energy between gas atoms and solid surfaces); Lawrence Research Student, Lieut.-Col. E. C. G. Maddock (tuberculosis); Tyndall Mining Research Student, Mr. A. G. R. Whitehouse (loss of salts from the body in sweating and the passage of water through the skin with and without sweating). Through the bequest of the late Mrs. Sollas, the capital of the Moseley Fund has been increased to more than twice its former value, so an additional studentship has been created; the two studentships will be awarded for work in physics or chemistry and for biological work bearing on pathology respectively. The Tropical Diseases Committee, with the aid of the Anonymous Bequest Fund, has instituted a research into kala-azar in Mediterranean countries, which is being conducted by Dr. Saul Adler, of the Hebrew University of Jerusalem. Grants amounting to £6002 have been allotted from the general fund by the Government Grant Committee, and ten grants, amounting to £1600, have been made from the Government Publication Grant.

We print below extracts from the remarks made by the president on the recipients' scientific work at the presentation of medals.

Presentation of Medals.

COPLEY MEDAL, AWARDED TO SIR WILLIAM BRAGG.

To the rapid advance of experimental physics in the last thirty years, Sir William Bragg has made conspicuous contributions by his pioneering researches in radioactivity, X-rays, and crystallography. He was the first to realise, in 1904, the characteristic difference to be expected in the nature of the absorption of the massive α-particle and the light β-particles expelled from radioactive substances. His experimental researches brought out clearly

the rectilinear path of the α-particles and their limited range of travel. In collaboration with his students, he examined in detail the variation of the ionisation of the α-particle along its path and its absorption by different kinds of matter. In his researches in X-rays and γ-rays, he was impressed by the difficulty that these high frequency radiations behaved like projected corpuscles—a difficulty which has only been in part resolved to-day. Following the discovery by Laue of the diffraction of X-rays by crystals, he was the first to develop a method for showing that ordinary X-radiation gave bright lines superimposed on a continuous spectrum. This reflection method of studying the spectrum of X-rays has proved of great importance to the development of knowledge. In the hands of Moseley, it supplied a means of showing that the atoms have all a similar structure and that their properties are defined by a whole number. In the hands of Sir William Bragg and his son, Prof. W. L. Bragg, it has provided a powerful tool for unravelling the structure of crystals. In this important development, which has added widely to our knowledge, Sir William Bragg has taken an active part, not only by his own researches but also by the direction of an important school of research on this subject at the Royal Institution.

RUMFORD MEDAL, AWARDED TO PROF. P. DEBYE.

Prof. Debye introduced and developed a theory of the specific heats of solids which is of fundamental importance. By it, for the first time, the main phenomena relating to specific heats and their variation with temperature were quantitatively explained. He has made important contributions to the theory of the scattering and reflection of X-rays. Independently of Compton, he put forward the quantum theory of the change of frequency due to the scattering of X-rays—the Compton effect. He was one of the inventors of the powdered crystal method of X-ray crystal analysis. By his introduction of the idea of spatial quantisation and by his investigations relating to the electric and magnetic properties of molecules he did much to advance our understanding of radiation and molecular phenomena. In collaboration with Hückel, Debye has developed a theory to account for the properties of strong electrolytes which has many important applications.

ROYAL MEDAL, AWARDED TO PROF. O. W. RICHARDSON.

In his earlier work, Richardson laid the foundation of thermionics. He was the first to study in detail the escape of electrons from hot bodies in a vacuum and to give the correct interpretation of the phenomena. His work on photo-electric emission was also of fundamental importance, and in it many of the now generally accepted ideas relating to interaction between radiation and matter were suggested. Among many important contributions in other fields was the prediction and calculation of the gyromagnetic effect—the rotational torque accompanying the magnetisation of a rod. In addition, he has done important work on electron emission associated with chemical action. He and his students have contributed largely towards filling up the gap between the ultra-violet and X-ray spectra. His main work in recent years has related to the hydrogen molecule, and has afforded a detailed test of the new quantum mechanics when applied to one of the simplest structures for which the old quantum mechanics breaks down.

ROYAL MEDAL, AWARDED TO PROF. J. E. MARR.

At a time when few believed it possible, Prof Marr discerned a delicate time-scale in the Lower Palæozoic Rocks, chiefly in the Lake District and North Wales, and applied it to elucidating the development of life and earth-structure. After testing his results in Scandinavia and in Bohemia he was able to make further use of them in setting in order corresponding rocks in South Wales. He has worked out the structure, origin, and development of the mountains, lakes, and rivers in Lakeland and elsewhere in the north of England. His work in association with Dr. Harker on the metamorphism brought about by the great mass of granite of Shap Fell on the rocks into which it was injected has become classic, and has inspired the rapid advance now being made in kindred studies. Of recent years he has contributed largely to knowledge of the Cambridge district, and particularly of the Pleistocene deposits and their relation to early man there and in East Anglia generally.

DAVY MEDAL, AWARDED TO PROF. R. ROBINSON.

By his investigations of the chemistry of the alkaloids, Prof. Robinson has made notable additions to the knowledge of the structure of these complex substances, and by experiment extended by theoretical discussion he has strikingly indicated possible mechanisms of their formation in Nature. He has also carrie[d] out brilliant synthetical work in connexion with th[e] colouring matters of flowers. His theoretical studie[s] of the mechanism of organic reactions, in particula[r] substitution in aromatic compounds, have led t[o] results of great value in that they enable a very wi[de] range of reactions to be considered from a comm[on] point of view.

DARWIN MEDAL, AWARDED TO PROF. JOHANNES SCHMIDT.

Dr. Johannes Schmidt is at the same time a distinguished oceanographer and a recognised research worker in genetics of animals and plants. The number and extent of the voyages in small research vessels which Dr. Schmidt has accomplished with success; his large and varied collections of the pelagic fauna and flora, and the remarkable series of observations made under his direction, on the physical and chemical phenomena of the sea, give him an undisputed place in the first rank of those scientific explorers whose labours have built up our knowledge of the oceans of the world. His researches on the life-history of the fresh-water eel and the discovery of its breeding places far out in the Atlantic are widely known. Dr. Schmidt's breeding experiments on the tropical fresh-water fish, *Lebistes*, carried out in the Carlsberg Physiological Laboratory at Copenhagen, are of much interest, whilst his investigations on the local races of the viviparous blenny (*Zoarces viviparus* L.) are of outstanding importance and originality.

HUGHES MEDAL, AWARDED TO SIR VENKATA RAMAN.

Sir Venkata Raman is one of the leading authorities on optics, in particular on the phenomenon of the scattering of light. In this connexion, about three years ago he discovered that the light's colour could be changed by scattering. This had been predicted theoretically some time before, but in spite of search the change had not been found. The 'Raman effect' must rank among the best three or four discoveries in experimental physics of the last decade. It has proved, and will prove, an instrument of great power in the study of the theory of solids.

Polar Front Analysis.

FIVE years ago Dr. J. Bjerknes, of Bergen, Norway, visited the forecasting branch of the London Meteorological Office to demonstrate the methods of weather forecasting that had been developed by him and his colleagues. These methods had been arrived at in the first place because of a dearth of telegraphic reports from foreign countries during the War, which made it possible to progress only by securing more numerous local telegraphic reports giving an unusual wealth of information about conditions in Norway. Such a direction of development is contrary to that generally followed in synoptic meteorology in other countries, the natural course during the past few decades having been constantly to extend the network of stations to cover an increasingly large area, as it has been realised more and more that many weather phenomena can only be explained by tracing the past history of the wind currents involved during several days, which may involve the construction of 'trajectories' several thousand miles in length. Sir Napier Shaw has been prominent in these developments, and his "Life History of Surface Air Currents" is a notable landmark of progress on those lines. Nevertheless, as was shown by the French meteorologist Durand Gréville at a competition in weather forecasting held at Liège in 1905, it is equally true that many phenomena can be explained only by a very detailed study of local variations of wind and pressure in a portion of a single cyclonic depression, and this line of advance has not been followed nearly to the extent that it deserves.

Dr. Bjerknes has left as a memento of his visit to London a paper * which deals with three meteorological situations analysed by his 'polar-front' method, full use being made of the large number of autographic records of wind, pressure, temperature, etc., that are maintained in Great Britain. The spacial distribution of the masses of 'polar' and 'equatorial' air that according to the Norwegian school of meteorology are the fundamental elements of the cyclonic depressions of middle and high latitudes, and possibly even of tropical cyclones, is not the main subject matter of this paper, which is concerned rather with a demonstration of certain ways in which a 'front', that is, the line or band separating such different air masses, may be modified either by downward movement of air within the cold polar air mass or upward movement of air in a transitional band separating polar and equatorial air masses. Three cases covering the periods Mar. 30–April 1, 1925, Feb. 10–11, 1925, and Jan. 22–23, 1926, are analysed.

It is not possible in a short space to give more than an outline of the subject matter of the paper. As some of the ideas introduced are published here for the first time, the paper should be read by all who wish to follow the progress of this interesting school of meteorological thought. It is doubtful whether the pursuit of this method of analysis is likely to lead to an understanding of the causes of formation and maintenance of depressions, but it is none the less almost indispensable for explaining certain weather sequences, and as an aid to greater precision in making forecasts for periods up to about twenty-four hours ahead, and especially for periods of six or twelve hours ahead. The application to longer periods is normally unpracticable, because the complexity of meteorological conditions makes it impossible to get much beyond a kind of extrapolation of tendencies revealed by a sequence of synoptic charts. The causes of acceleration or retardation of fronts, which last are so important in controlling the upward and downward motion of the air masses on either side of a front, are still obscure.

* Practical Examples of Polar-front Analysis over the British Isles in 1925–26, by Dr. J. Bjerknes. Meteorological Office Memoirs, No. 50. (London: H.M. Stationery Office, 1930.)

Body and Mind.

IN a paper read before Section J (Psychology) of the British Association at Bristol, Dr. H. Banister discussed the psychology of the tuberculous patient. He quoted various authorities who have attributed to tuberculosis a great variety of mental changes. The disease has been regarded by some to be stimulating to intellectual activity, even to the extent of producing the genius; others consider it to be the cause of neurasthenic syndromes, hysterical manifestations, certain types of psychosis, and homicidal tendencies. As his own view, Dr. Banister insisted that the mental mechanisms of tuberculous patients are the same as those of the healthy individual. Their apparently peculiar psychology is not dependent on tubercle infection; it is the ordinary reaction of the mind to the inhibitions, restrictions, and difficulties which inevitably accompany the disease, and is absent only in those who can readily adapt their outlook and their lives to the new and limiting circumstances. In some persons such adaptation, coupled with a tendency to day-dreaming which can be present during any chronic illness, may bring out the creative tendencies of the individual, expressed in literature and the arts. The state of undue exaltation and optimism often stated to be characteristic in phthisis, is very infrequent, and is simply a manifestation of the dissociation which might follow any severe mental stress.

Considering the effects of the mental attitude of the tuberculous, Dr. Banister stated dogmatically that the patient with a hopeful outlook has a far better chance of arresting the disease than the one who is constantly in a state of despair and anxiety. This points to an extremely important line of treatment. The patient must be encouraged to aim for a life of useful though limited activity, to beware of invaliding himself beyond the degree required, and to avoid anxiety and worry. This is not always easy for the rich; for those of limited means it is, in the home, almost impossible; but that it can be successful under suitable conditions is fully confirmed by the results obtained at Papworth Village Settlement.

A related topic was discussed in a paper before Section I (Physiology) of the Association by Mr. P. Watson-Williams, who referred to chronic toxæmia as a cause of mental disorder and alteration in character. He pointed out that chronic infections can give rise to mental changes and produce disorders of conduct resulting in the unfortunate victim being charged with misdemeanours or criminal actions. As a typical illustration, he cited the well-known character changes which often follow epidemic encephalitis in children. Of equal importance, but more readily overlooked, is toxic absorption from some focus of sepsis. The results of such toxæmia vary within wide limits, from a mild depression to a certifiable psychosis with suicidal tendencies.

While recognising that there must be convincing evidence before attributing misconduct to a toxic mental breakdown, Mr. Watson-Williams emphasised the necessity for expert medical examination to determine whether a delinquent should be dealt with in a hospital rather than before a magistrate.

ordinances founding a chair of psychology and a chair of geography in the University.

Dr. J. Duncan White was appointed as University lecturer in radiology in succession to Dr. J. M. Woodburn Morison.

Intimation was received of a bequest by Mrs. A. M. Cameron, widow of the late Surgeon Lieut.-Col. Lewis Cameron, the bequest to be for the constitution of a Lewis Cameron Fund for a prize in connexion with bacteriology or the diagnosis of disease, as the Court may from time to time decide.

On the recommendation of the Senatus, the Court resolved to institute a course of twenty-five lectures in acoustics in the Department of Natural Philosophy for students in music.

Having consulted the General Council, the Court concurred in a proposal of the Scottish Universities Entrance Board to adopt a regulation including natural science among the subjects of the Preliminary Examination.

Fishes from the *Dana* Expedition.

DR. C. TATE REGAN and Miss Ethelwynn Trewavas have described a large and unique collection of fishes in "The Fishes of the Families Stomiatidæ and Malacosteidæ" (The Danish *Dana* Expedition, 1920–22, in the North Atlantic and Gulf of Panama. Oceanographical Reports edited by the *Dana* Committee, No. 6).

The closely related families Astronesthidæ and Chauliodontidæ have already been dealt with, and the present work is a complete systematic revision of the Stomiatidæ and Malacosteidæ, except for the ... The report is based on the *Dana* collection and on the specimens in the British Museum (Natural History), and in addition several type specimens have been examined from elsewhere. Four new genera, twelve new sub-genera, and seventy-three new species of the Stomiatidæ and four new species of the Malacosteidæ are here described, the new species exceeding in number those previously known. They are all oceanic and probably predaceous, mostly living at no great depth below the surface.

Of the nineteen genera described by Dr. Tate Regan and Miss Trewavas, all but one are known to occur in the North Atlantic. The presence of a barbel is general, and there are two series of photophores on each side of the lower part of the body and a single series on the tail. Behind the eye is a large organ with luminous surface which can be turned downwards and inwards into a pocket and so concealed. The authors suggest that the serial photophores possibly serve as recognition marks, enabling the members of a shoal to keep in touch with one another, and that the post-ocular luminous organ may give light for vision, but the use of the barbel in these fishes of the upper and middle layers of the ocean is more difficult to see. It is suggested that it may be sensory, perhaps receiving impressions that indicate the approach of other fishes, or, when very long and simple, may be tactile. The bulbs and swellings which often occur on the barbel are glandular, similar to the luminous organs on the body, and are probably also luminous, serving as lures. In some species, especially those belonging to the genus *Eustomias*, the form of the barbel is the chief distinguishing mark.

Very interesting changes are shown in some of the young stages of these fishes. In *Aristomias* in the family Malacosteidæ and *Eustomias* and *Idiacanthus* in the Stomiastidæ there are young specimens of the same species with juvenile characters which are as large or larger than those with the structure of the adults, indicating a rapid transition from one stage to another, possibly accompanied by a decrease in size.

University and Educational Intelligence.

CAMBRIDGE.—The Appointments Committee of the Faculty of Physics and Chemistry has appointed Dr. R. G. W. Norrish, of Emmanuel College, to be Humphrey Owen Jones lecturer in physical chemistry for three years.

The General Board recommends (1) that a professorship of geography be created as from Jan. 1, 1931, that the stipend attached to the professorship be £1200 a year, and that the present reader in geography, Mr. F. Debenham, be the first holder of the chair; (2) that a professorship of experimental psychology be created as from Jan. 1, 1931, that the stipend attached to the professorship be £1200 a year, and that the present reader in experimental psychology, Mr. F. C. Bartlett, be the first holder of the chair.

DURHAM.—Lord Londonderry has been appointed Chancellor of the University in succession to the late Duke of Northumberland.

EDINBURGH.—At a meeting of the University Court held on Nov. 24, it was resolved to proceed with

... Pleistocene deposits ... in East Anglia ...

ROBINSON.

ACCORDING to the Report of the Board of Management of the London School of Hygiene and Tropical Medicine, presented to the Court of Governors on Nov. 28, the financial situation of the School is satisfactory up to a point, the Court of the University having secured to the School an Exchequer grant for a term of years at the rate of £40,000 per annum. The School, however, has to supplement this by voluntary effort, not only to meet the cost of the present programme, but also to meet the cost of developments, especially in regard to industrial medicine and hygiene, which are already pressing for attention. The report on the work of the School during the first year of occupation of the premises, the gift of the Rockefeller Foundation, which were opened by the Prince of Wales in July 1929, stated that no less than 217 post-graduate students had attended the courses and a further 75 non-medical persons proceeding to the tropics had attended the lectures in tropical hygiene. Reference was also made to the assistance rendered by the Seamen's Hospital Society, and to the extension it has recently made to the Hospital for Tropical Diseases, which provides a valuable centre for the teaching of tropical medicine in association with the School. A beginning has been made with the teaching of industrial physiology and medical industrial psychology.

THE annual conference of the Geographical Association will be held on Dec. 31–Jan. 5 at the Imperial Institute, South Kensington, S.W.7, and the London School of Economics, Houghton Street, W.C.2, under the presidency of Mr. B. B. Dickinson, who will deliver his presidential address on Jan. 1. The programme includes a discussion and exhibition on school journeys, exhibition of maps showing agricultural distribution in Scotland (Mr. H. J. Wood), regional study of the Chod villages of south-west Bohemia (a Leplay House group), lantern lecture by Major R. W. G. Hingston on the 'tree-roof' of the Guiana forest and by Miss R. M. Fleming on regions of Russia, a paper on the distribution of houses in England and Wales as a population index (Dr. P. W. Bryan), a discussion for secondary school teachers of Mr. B. C. Wallis's paper on geography from the point of view of the examiner, and another for primary school teachers on geography and the extension of the school age. Reference is also made to the discussion on the teaching of geography arranged by the Conference of Educational Associations for Jan. 5 at University College, Gower Street, W.C.1. A publishers' exhibition of books and apparatus will be open upon Jan. 1–3. Information regarding the meeting of the Geographical Association can be obtained from the Clerk of the Association, Municipal High School of Commerce, ... Street, M...

Historic Natural Events.

Dec. 7, 1663. High Tide.—Pepys records that 'last night was the greatest tide ever known in the Thames; all Whitehall was drowned".

Dec. 7, 1873. "Cattle-Show" Fog. During the whole of the week beginning Dec. 7, the British Isles were under the influence of an anticyclone. Hard rosts and dense fogs occurred over the whole country. In London the fog was continuous throughout the week, which was that of the annual Cattle Show, and caused great inconvenience. It was followed by a great increase in the number of deaths from respiratory diseases.

Dec. 7, 1879. Great Cold in Central Europe.—December 1879 was the coldest month of the century France and central Europe. The frost began on Nov. 22 25, and reached its greatest intensity on Dec. 7, when it extended over France, Switzerland, Italy, and even northern Africa, for snow fell in Tunis. At Montsouris, Paris, a temperature of $-11°$ F. was recorded in the shade, and farther east, at Langres, $-22°$ F. In Paris there were 75 days of frost, 33 in succession, and in France 50 persons died of cold. The Seine, Yonne, and Loire were frozen. There was heavy snow in Paris. The Dutch waterways were frozen for 54 days. On Dec. 8 the Zuider Zee became an ice lake. By way of contrast, the winter was not cold in Russia. A second period of cold came at the end of January, but February was very warm. The beginning of December was very cold in England and Scotland (see Dec. 4), but afterwards the cold was not excessive and the Thames was not frozen over.

Dec. 8-9, 1886. Storm and Low Barometer over Eastern Atlantic.—This storm was notable for its great extent, the low barometer in its centre, its duration, and the violence of its winds. It appeared off the west of Ireland on the evening of Dec. 7 and travelled due eastwards across the south of England. At Belfast on the afternoon of Dec. 8 the barometer to 27·38 inches (927·2 mb.). The average wind velocity reached 80 miles per hour at Fleetwood from 8.30 to 9.30 A.M. on Dec. 9, and exceeded 70 miles per hour from 8 A.M. to 4 P.M. The gale extended over the whole area from Stornoway to Corunna, more than 1100 miles. A sharp squall with thunder, lightning, and hail passed over London at 9 A.M. on Dec. 8. On the coasts no fewer than 217 vessels were recorded as lost or damaged, while two lifeboats were capsized near Fleetwood, with the loss of 27 lives.

Dec. 9-11, 1671. Glazed Frost in Somerset.—Although there was no ice on any water, the rain of these days in Somerset froze as it fell. An ash branch weighing three-quarters of a pound had 16 pounds of ice on it, the ice being five inches in circumference. Vast numbers of trees were destroyed by the weight of the ice.

Dec. 10, 1149. Severe Winter in England.—The winter of 1149-50 was very severe in England and the Netherlands. The Thames was frozen from Dec. 10 until Feb. 19, and was used as a highway for carriages and horses. The sea off Holland was frozen three miles from the shore. The winter caused a severe famine, and the whole year was very unfavourable.

Dec. 12, 1901. Snowstorm over England.—A deep barometric depression travelled eastward along the English Channel on Dec. 12-14, and during these three days strong north-easterly winds prevailed over the British Isles, while a violent snowstorm raged over most of England, especially the north Midlands. Enormous damage was done to telegraph wires, the north of England being isolated from London, while railway traffic was completely disorganised. Great drifts were formed in hilly districts, blocking roads and causing the loss of many sheep.

Dec. 13, 1795. Meteorite.—The controversy as to whether so-called 'thunder-bolts' ever actually fell from the sky was ended in 1795, when an aerolite was observed to fall on Dec. 13 at Wold Cottage, Thwing, near Scarborough. This aerolite, which weighs 56 lb., is now in the British Museum (Natural History).

Societies and Academies.

LONDON.

Mineralogical Society, Nov. 4.—**Arthur Russell**: An account of British mineral collectors and dealers in the seventeenth, eighteenth, and nineteenth centuries. A first instalment of a series of short biographies dealing with:—Nehemiah Grew, F.R.S. (1641 1712), William Borlase, F.R.S. (1696 1772); Rudolf Erich Raspe (1737–1794); and Philip Rashleigh, F.R.S. (1729 1811). **M. H. Hey**: On cupriferous melanterite from the Skouriotissa mine, Cyprus. A crystallographic study of a well crystallised specimen from an ancient working (perhaps Roman) in the Skouriotissa mine, revealed a very peculiar habit tabular to $b(010)$, and the presence of the new forms $x(161)$, $y(231)$, $g(112)$, $q(102)$, and $\beta(150)$. A partial analysis shows the presence of 7·7 per cent. $CuSO_4{,}7H_2O$.—**C. E. Tilley**: On the dolerite-chalk contact-zone of Scawt Hill, Co. Antrim. The production of basic alkali rocks by the assimilation of limestone by basaltic magma. (With chemical analyses by **H. F. Harwood**): Assimilation of limestone at the contact of a dolerite intrusion with the chalk at Scawt Hill gives rise to a hybrid zone built up of pyroxene-rich rocks (pyroxenites), titanaugite-melilite rocks, and basic rock-types bearing nepheline (theralite and nepheline-dolerite assemblages). The segregation of a basic alkali residuum is the complementary process in the precipitation of magnesia-rich pyroxene in the pyroxenites. Plagioclase is resorbed and gives place to a titaniferous lime-augite rich in alumina, melilite, and nepheline, while perovskite, aegirine, and wollastonite are other products in the hybrid zone. **Frank Smithson**: A simple method of observing the magnetic properties of mineral grains. The tests are made with softened steel needles attached to the poles of a horse-shoe magnet, a strong field being obtained when the points are 1 mm. or so apart. The attraction is observed under the microscope. **M. H. Hey**: On studies of the zeolites (1). General review. A short review of the general properties of the zeolites, with some suggestions on the interpretation of the available data, and a comparison of the zeolites with the clays, ultramarines, permutites, and 'artificial zeolites'.

Royal Meteorological Society, Nov. 19. J. Edmund Clark, I. D. Margery, R. Marshall, and C. J. P. Cave: Report on the phenological observations in the British Isles, December 1928 to November 1929. A year of extreme conditions resulted in average results for 1929. Winter migrants, such as fieldfares and redwings, fled from usual haunts to avoid the cold, but reappeared as welcome guests in south Ireland and south-west England. Sharp spells of cold in April, May, and June neutralised the alarming number of queen wasps. In the table of flowering dates, all are late in England and Wales, though decreasingly so: from 17 to 14 days for the hazel and coltsfoot in February, to 1 and 2 days for the devil's bit scabious and ivy in early August and late September. That the determining factor was cold of continental type

spreading exceptionally in proportion to propinquity is well shown by the district values. Our earliest bird record, the song of the thrush, and the honey bee date for insects, tell the same tale. The exceptional nature of the March warmth and sunshine is best illustrated by the insects: on the average the queen wasp appears two days after blackthorn blooms; in 1929 ten days earlier. It was more than a month early in Scotland W., and the orange tip butterfly nearly as much in Scotland E. The year's results in farm and garden as to quantity and quality showed a small balance on the credit side, due chiefly to the superb September. But to drought in the south-east was due a shortage of hay and straw, while in the far north, late comparatively in its harvest-time, the October deluge played sad havoc.—**A. V. Williamson** and **K. G. T. Clark**: The variability of the annual rainfall of India. Variability is defined as the percentage departure—irrespective of sign—from normal annual rainfall which has occurred at a given station in half the years of the period 1890–1923. Two generalisations are submitted: (1) the lower the rainfall the greater variability tends to be; (2) rainfall is less reliable when it is characteristically concentrated than when it is well distributed in time. A map of India divided into zones by means of "lines of equal-variability" has been prepared.

PARIS.

Academy of Sciences, Nov. 3. **Bigourdan**: The Technological Institute of I. Porro. Historical account of the astronomical equipment of this observatory. **E. L. Bouvier**: The systematics of the Saturnioides of the family of Hemileuca. **Georges Claude**: The utilisation of the thermal energy of the sea. An account of the laying an iron tube, 2 km. in length, in the Bay of Matanzas, for the purpose of extracting cold water from the sea floor, to be utilised by the Claude-Boucherot plan.—**C. Camichel, J. Leclerc du Sablon**, and **L. Escande**: Experiments on the pipes supplying water to the Miègebat power station. **N. Achieser**: The polynomials of Tchebyscheff for two segments.—**Henri Dumas**: The generalisation of a theorem of Mandelbrojt.—**Mandelbrojt**: Some theorems on holomorph analytical functions limited in an infinite region.—**Jean Chazy**: The velocity of propagation of the Newtonian attraction.—**G. Wataghin**: The relations of indetermination in the theory of quanta.—**L. Goldstein**: The distribution of the electrons in the atom.—**Pan-Tcheng Kao**: The vibrations of piezoelectric quartz along the optic axis. Quartz possesses three fundamental frequencies related to the three axes, and this is not in contradiction with Curie's law.—**A. Dargenton**: The refraction of pencils of right lines.—**A. Couder**: Spectrograph with a non-inclined plate. **R. Tréhin**: The absorption of aqueous solutions of hydrochloric acid in the ultra-violet.—**R. Zouckermann**: The phosphorescence phenomena presented by fused silica discharge tubes. The phenomena described are analogous with those described by Curie as resulting from the action of radium rays on various substances and by Wiedemann and Schmidt when studying the action of the cathode rays.—**J. Giuntini**: The compounds of tartaric acid and copper. Solutions of the copper tartrates were prepared by dissolving increasing proportions of precipitated copper hydroxide in tartaric acid and these were examined for rotatory power and dichroism. The discussion of the data from the point of view of formation of definite compounds is reserved for a later communication.—**E. Darmois** and **Jean Pierre Pérez**: The variation of the rotatory power of the camphorsulphonates in the presence of neutral salts.—**Jean Becquerel** and **W. J. de Haas**: The paramagnetic rotatory power of crystals of xenotime at very low temperatures and on the paramagnetic saturation. The temperatures were taken down to 4·2° abs. (liquid helium) with a magnetic field of 27,000 gauss. Under these conditions the paramagnetic saturation is almost complete. Curves have been obtained representing the rotations as functions of H/T, where H is the magnetic field and T the absolute temperature.—**H. A. Kramers**: Paramagnetic rotation in uniaxial crystals of the rare earths.—**Desmaroux** and **M. Mathieu**: The X-ray study of the gelatinisation of nitrocellulose.—**A. Kling** and **A. Lassieur**: The hydrogen exponent (pH) of water. In two earlier communications the authors have found by two independent methods a value 5·8 for the pH of water. This figure has been criticis[ed] on the ground that the experiments may have bee[n] vitiated by the presence of a trace of carbon dioxi[de] in solution. An experiment is described in which th[e] water used was directly distilled from a platinu[m] vessel after addition of caustic soda, the distillatio[n] being carried out in a current of pure hydrogen. Th[e] water again gave a pH of 5·8 by a zero electrometr[ic] method, confirming the previous results.—**Al. Yak[i]mach**: A complex compound of quadrivalent van[a]dium cyanide. The preparation of the compound $K_2V(CN)_6$ is described. **Joseph Robin**: The migration of the amino groups in the arylamines derived from the diarylarylethinylcarbinols. The constitution of the compounds obtained. **Paul Bruère**: The colorimetric micro-reactions of the glutenogen proteids and of the cellulose gels of the wheat grain.—**J. Beauverie** and **J. Treyve**: The survival and development of green plants during periods up to nearly two years in hermetically closed receivers. **Fontaine**: The parallelism existing in fish between their resistance to variations of salinity and the independence of their interior medium.—**H. Laugier** and **Mlle. L. Lubinska**: Reflex excitability and refractory phenomena in the nerve centres.—**Georges Blanc** and **J. Caminopetros**: The sensibility of *Citillus citillus* to the Mediterranean kala-azar. This marmot is so sensitive to kala-azar infection that it is undoubtedly the best experimental animal for the study of this disease and its mode of transmission.—**J. Magrou** and **Mme. Magrou**: Action at a distance and the development of the egg of the sea urchin. New experiments.

LENINGRAD.

Academy of Sciences, *Comptes rendus*, No. 15, 1930.—**V. Ipatjev**: Cellulose from sugar. An analysis of the cellulose obtained by Prof. E. Schmidt, Munic[h], from monosaccharides.—**A. Čičibabin**: Acids in petroleum.—**A. Karpinskij**: (1) Studies of [prob]lematic objects and phenomena: a study of the [rem]nants of *Helicoprion*.—(2) A problematic fossil f[rom] the Palaeozoic deposits of the northern Ural[s]: description and discussion of *Proamphibia proble[ma]tica*, represented by a fossilised scaly skin.—(3) [A] cast-iron resembling in structure a piece of w[ood]. Chemical, metallographic, and microscopic analys[is of] an object found in a furnace and representing a [piece] of cast-iron, with all the details of structure of wo[od].—**V. Chlopin** and **B. A. Nikitin**: The radium conte[nt of] the petroliferous waters of the Grozny area. [The] concentration of radium in some samples was high, namely, 1/28, 3/28, and 1/31.—**V. Diary of Societies.

FRIDAY, DECEMBER 5.

ROYAL SOCIETY OF MEDICINE (Otology Section), at 10.30 A.M.—Dr. G. Riddoch, Dr. A. B. Rosher, and others: Discussion on Intracranial Complications of Otitic Origin: Neurological and Pathological Investigation.

ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 5.

PHYSICAL SOCIETY (at Imperial College of Science), at 5.—M. Fahmy: A Point of Analogy between the Equations of the Quantum Theory and Maxwell's Equations.—B. K. Johnson: Sources of Illumination for Ultra-violet Microscopy.—W. A. Wood: The Influence of the Crystal-orientation of the Cathode on that of an Electro-deposited Layer.—C. A. Kloss: Relations between the Fundamental Physical Constants.—Demonstration by Prof. G. B. Bryan of some Stroboscopic Effects.

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (in Muspratt Lecture Theatre, Liverpool University), at 6.—U. R. Evans: The Protection of Metals by Painting.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Prof. W. E. S. Turner: Machinery and Methods of Manufacture of Sheet Glass.

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (at Engineers' Club, Manchester), at 7.—Dr. T. Callan: The Estimation of Minute Traces of Copper.—Dr. F. C. Wood: (a) The Reaction of Formaldehyde Derivatives with Cellulose; (b) The Formation of Cellulose Monomethylene Ether; (c) The Action of Grignard Reagent on Cellulose.—C. M. Whittaker: Some Notes on Viscose Dyeing.—J. M. Preston: A Skin Effect on Viscose Rayon.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group) (Informal Meeting), at 7. Discussion on The Camera for the Pictorialist.

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7.—O. Howarth: The Metering of Three-Phase Supplies.

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7.30.—R. L. Mayston: Oil Burning for Domestic Central Heating.

GEOLOGISTS' ASSOCIATION (in Architectural Theatre, University College), at 7.30.—Dr. A. K. Wells: A Journey through South and West Africa, with special reference to Igneous Phenomena (Lecture).

LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemistry Section) (jointly with Leicester Association of Engineers) (at College of Technology, Leicester), at 7.30.—G. F. O'Riordan: Recent Developments in Chemical Engineering.

ROYAL SOCIETY OF MEDICINE (Anæsthetics Section), at 8.30.

SATURDAY, DECEMBER 6.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir E. Denison Ross: Persia and the Persians (1): The Country and its History.

INSTITUTE OF BRITISH FOUNDRYMEN (Lancashire Branch) (at College of Technology, Manchester), at 4.—S. H. Russell: Foundries—and Foundries.

[INSTI]TUTE OF BRITISH FOUNDRYMEN (Scottish Branch) (at Royal Technical [Co]llege, Glasgow), at 4.—A. Harley: The Production of an Aluminium [Al]loy Casting.

[C]HEMICAL SOCIETY (in Department of Physiology, London Hospital [Medic]al College), at 5.—H. Chick and A. M. Copping: Observations on the Water Soluble B Vitamin Complex.—G. T. Calthrop and J. R. Marrack: Carotinæmia in Diabetes.—J. R. Marrack and F. Campbell Smith: Quantitative Aspects of Immunity Reactions.—Prof. C. Lovatt Evans, Chao Tsai, and F. G. Young: The Influence of Adrenaline on Glycogen Distribution in the Cat.—Demonstrations:—F. Campbell Smith and E. R. Holiday: Photo-electric Spectrophotometry of the Ultra-violet using the Hydrogen Discharge Tube as the Source of Radiation.—J. R. Marrack and F. Campbell Smith: A Kataphoresis Apparatus.—K. S. Thompson: A Precipitin Reaction with Bee Stings.

INSTITUTE OF BRITISH FOUNDRYMEN (West Riding of Yorkshire Branch) (at Technical College, Bradford), at 6.30. F. Griffiths: Some Aspects of Modern Foundry Practice.

MONDAY, DECEMBER 8.

CAMBRIDGE PHILOSOPHICAL SOCIETY (in Cavendish Laboratory), at 4.30.—L. H. Gray: The Photoelectric Absorption of Gamma Rays.—L. G. Vedy: On the Rotation of Dielectrics in Electrostatic Fields and Related Phenomena.—*Papers to be communicated by title only*:—W. G. Welchman: On Elliptic Quartic Curves with Assigned Points and Chords.—Dr. S. Verblunsky: Note on Continuous Functionals.—A. Oppenheim: Note on some Linear Diophantine Inequalities.—Prof. C. G. Darwin: The Diamagnetism of the Free Electron.—Prof. J. B. S. Haldane: A Mathematical Theory of Natural and Artificial Selection. Parts VII., VIII.—G. de B. Robinson: On the Rotation Groups of Four Dimensions.—Prof. L. M. Milne-Thomson: On the Operational Solution of Linear Finite Difference Equations.—Dr. D. R. Hartree: The Propagation of Electromagnetic Waves in a Refracting Medium in a Magnetic Field.—H. R. Hassé: The Calculation of the van der Waal Forces for Hydrogen and Helium at Large Interatomic Distances.—Dr. G. S. Carter: Aquatic and Aerial Respiration in Animals.—Von Gottfried Fraenkel: Die Mechanik der Orientierung der Tiere im Raum.—G. C. Hirsch: The Theory of Fields of Restitution with Special Regard to the Phenomena of Secretion.

ROYAL GEOGRAPHICAL SOCIETY, at 5.—Prof. J. W. Gregory: The Earthquake off the Newfoundland Banks.

INSTITUTION OF AUTOMOBILE ENGINEERS (Birmingham Centre) (at Queen's Hotel, Birmingham), at 7.—H. C. Armitage: Machine Tools from the Manufacturing Users' Point of View.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—A. O. Gibbon, Lt.-Col. K. Edgcumbe, and others: Discussion on Impulse *versus* Synchronous Time Service.

INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (in University, Liverpool), at 7.—O. Howarth: The Metering of Three-phase Supplies.—J. Urmston: The Electrical High-pressure Testing of Cables and the Localisation of Faults.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Eastern Section) (at Armstrong College, Newcastle-upon-Tyne), at 7.—S. G. Brown: Loud-speakers since their Conception with Gramophone Pick-ups and Wireless Recording Apparatus.

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at University, Birmingham), at 7.—D. B. Hoseason: The Cooling of Electrical Machines.

SOCIETY OF CHEMICAL INDUSTRY (Yorkshire Section) (jointly with Institute of Chemistry—Leeds Area Section) (at Great Northern Hotel, Leeds), at 7.15.—Dr. W. J. S. Naunton: Antioxidants.

ROYAL SOCIETY OF ARTS, at 8.—Prof. C. R. Darling: Modern Domestic Scientific Appliances (Cantor Lectures) (3).

CHARTERED SURVEYORS' INSTITUTION, at 8.—A. T. A. Dobson: The Land Drainage Act, 1930.

TUESDAY, DECEMBER 9.

ROYAL SOCIETY OF MEDICINE (Therapeutics and Pharmacology Section), at 5.—Discussion on The New Mercurial Diuretics and their Uses in Medicine.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Prof. E. A. Milne: Stellar Structure and the Origin of Stellar Energy (2).

INSTITUTE OF MARINE ENGINEERS, at 6.—Dr. J. Tutin and A. C. Hardy: Modern Developments in Ship Design, with Special Reference to Propulsion.

INSTITUTE OF METALS (Swansea Section) (at University College, Swansea), at 6.15.—W. Andrews and H. Martin: Copper Welding.

INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—S. G. Brown: Loud-speakers since their Conception with Gramophone Pick-ups and Wireless Recording Apparatus.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Western Centre) (at Engineers' Club, Manchester), at 7.—Dr. J. J. Rudra and Prof. M. Walker: The Theory and Performance of Phase Advancers.

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (Associate Members' and Graduates' Section) (at Borough Polytechnic), at 7.

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (Associate Members and Graduates' Section) (Manchester and District Branch) (at Milton Hall, Manchester), at 7.—P. G. Fairhurst: Paper.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Kinematograph Group), at 7.—Display of New Apparatus. Projection of Films.

INSTITUTE OF BRITISH FOUNDRYMEN (Lancashire Branch) (Burnley Section) (at Municipal Technical College, Burnley), at 7.15.—F. Harris: Survey in Making of Light Castings.

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Centre) (at King's Head Hotel, Coventry), at 7.30.—E. V. Pannell: Light Alloy Piston Development.

INSTITUTE OF METALS (North-East Coast Section) (at Armstrong College, Newcastle-upon-Tyne), at 7.30.—Prof. H. V. A. Briscoe: Properties of Coke.

INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Centre) (at 39 Elmbank Crescent, Glasgow), at 7.30.—D. D. Hoseason: The Cooling of Electrical Machines.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, at 8.30.—Prof. D. M. S. Watson: Endocrine Organs (Lecture).

ROYAL SOCIETY OF MEDICINE (Psychiatry Section), at 8.30.—Dr. N. H. M. Burke: Stigmata of Degeneration in relation to Mental Deficiency.

WEDNESDAY, DECEMBER 10.

INSTITUTION OF CIVIL ENGINEERS (Informal Meeting), at 6.—Dr. J. S. Owens: Atmospheric Pollution due to Combustion of Fuel, and Methods of its Prevention.
TEXTILE INSTITUTE (Midlands Section) (at Colleges of Art and Technology, Leicester), at 6.—W. Kershaw: Research in the Textile Industry.
TELEVISION SOCIETY (at University College), at 7.—T. Thorne Baker: Television in Natural Colours and the Fundamental Problems involved.
INSTITUTION OF AUTOMOBILE ENGINEERS (Leeds Centre) (at Metropole Hotel, Leeds), at 7.15.—Dr. H. E. Merritt: Trends in the Transmission.
BACUP TEXTILE SOCIETY (at Natural History Rooms, Bacup), at 7.30.—Dr. J. H. Kitson: Factory Hygiene.
INSTITUTION OF ELECTRICAL ENGINEERS (Hampshire Sub-Centre) (at University College, Southampton), at 7.30.—H. W. Taylor: Voltage Control of Large Alternators.
ROYAL SOCIETY OF ARTS, at 8.30.—A. L. B. Ashton: Persian Textiles.
EUGENICS SOCIETY (at Linnean Society), at 8.30.—Dr. M. Radford: Heredity in Education.
ELECTROPLATERS' AND DEPOSITORS' TECHNICAL SOCIETY (jointly with Faraday Society).—D. J. Macnaughtan: The Determination of the Porosity of Electrodeposits.—D. J. Macnaughtan and R. A. F. Hammond: The Influence of Small Amounts of Chromic Acid and of Chromium Sulphate in the Electrodeposition of Nickel.—D. J. Macnaughtan and A. W. Hothersall: 'Stopping Off' Materials for Use in the Electrodeposition of Nickel. S. Glasstone and J. B. Speakman: The Electrodeposition of Cobalt-Nickel Alloys.—W. J. Shutt and J. Stirrup: The Time Factor in Anodic Passivation of Metals.

THURSDAY, DECEMBER 11.

ROYAL SOCIETY, at 4.30.—Prof. J. Bordet: Les Théories des Bactériophages (Croonian Lecture) (*in English*).
LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5.—W. N. Bailey: An Extension of Meissel's Expansions in Kapteyn Series, and Some Similar Expansions.—Dr. R. A. Fisher and J. Wishart: The Derivation of the Pattern Formulæ of Two-way Partitions from those of Simpler Patterns.—Prof. L. M. Milne-Thomson: Ten Figure Table of the Complete Elliptic Integrals K, K', E, E'.—V. C. Morton and Dorothy S. Meyler: Quadrics and Quadric Cones of a Set of Three Associated Steiner Trihedral Pairs.—R. F. Whitehead: Ramanujan's Approximation for e^n.
ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Sir John Russell: The Agricultural Development of the Empire (2): Conquest of the Drought.
CHEMICAL SOCIETY (at Imperial College of Science), at 5.30.—Prof. W. A. Bone: Fifty Years' Experimental Research upon the Influence of Steam on the Combustion of Carbonic Oxide (1880–1930) (Liversidge Lecture).
ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6.30.—D. R. Pye: The Origin and Development of Heavy Oil Aero-Engines.
SOCIETY OF CHEMICAL INDUSTRY (Bristol Section) (jointly with Chemical Engineering Group) (in Chemical Department, University, Bristol), at 6.30.—S. Stephens: Modern Water Treatment.
INSTITUTE OF MARINE ENGINEERS (Junior Section), at 7.—E. W. Causton: Types of Internal Combustion Engines.
INSTITUTE OF METALS (Birmingham Section) (at Chamber of Commerce, Birmingham), at 7.—E. J. Dobbs: Plating.
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Colour and Kinematograph Groups), at 7.—Kinematograph Group: S. G. French: Some Kodacolor Films of the Italian Lakes.—Colour Group: Instantaneous Colour Photography. Some Comparative Tests of Bead and other Lantern Screens.
INSTITUTION OF ELECTRICAL ENGINEERS (Dundee Sub-Section) (at University College, Dundee), at 7.30.—A. V. Reis: Electricity and Mining—a Story of Progress.
NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Teesside Branch) (Informal Meeting) (at Cleveland Scientific and Technical Institution, Middlesbrough), at 7.30.—J. Crichton and others: Discussion on Shipbuilding in Japan and Russia.
OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7.30.—T. H. Court and Dr. M. von Rohr: New Knowledge on Old Telescopes.—Mrs. E. Gifford: On Interpolating Refractive Indices.—H. Buckley: On the Determination of the Transmission Factors of Coloured Step Lenses.
INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre—Dublin) (at Trinity College, Dublin), at 7.45.
INSTITUTION OF WELDING ENGINEERS (at Institution of Mechanical Engineers), at 7.45.—C. C. Hall: The Fabrication of Plant in Acid-Resisting Steels.
INSTITUTE OF METALS (London Section) (jointly with Institute of British Foundrymen) (at Chemical Society), at 8.—E. Player: Magnesium Alloy Castings.
ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at 11 Chandos Street, W.), at 8.15.—Major G. Shanks: Demonstration on the Pathology of Epidemic Dropsy in Bengal.—Sir Aldo Castellani: Minor Tropical Diseases.

FRIDAY, DECEMBER 12.

ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botany Department Lecture Room, Imperial College of Science and Technology), at 2.30.—The Purification of Waste Waters from Beet-Sugar Factories:—D. W. Cutler: Microbiological Aspects.—E. H. Richards: Biochemical Aspects.
ROYAL SOCIETY OF ARTS (Indian Meeting), at 4.30.—A. Wigglesworth: India's Commercial Fibres.
ROYAL ASTRONOMICAL SOCIETY, at 5.—E. A. Kreiken: (*a*) On the Relation of Colour and Spectral Type in the Different Galactic Latitudes; (*b*) On the Axial Rotation of the Stars; (*c*) Some further Remarks on the Rotation of the Stars.—Prof. H. N. Russell and R. S. Dugan: Apsidal Motion in Y Cygni and other Stars.
MALACOLOGICAL SOCIETY (at Linnean Society), at 6.
INSTITUTION OF MECHANICAL ENGINEERS, at 6.—V. E. Pullin: X-Rays in Engineering Practice.
NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle-upon-Tyne), at 6.—W. J. Rees: Refractories for Boiler Furnaces.
INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section), at 6.15.—W. D. Oliphant: Laboratory Method as met with in Wireless Technique.
SOCIETY OF DYERS AND COLOURISTS (Manchester Section) (at Literary and Philosophical Society, Manchester), at 7.—Short Papers.
OIL AND COLOUR CHEMISTS' ASSOCIATION (Manchester Section) (at Royal Institution, Liverpool), at 7.—A. W. C. Harrison: The Incorporation of Dry Pigments into the Medium.
SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (jointly with South Wales Section of Institute of Chemistry) (at Thomas' Cafe, Swansea), at 7.30.—Dr. P. M. Davison: The Structure of Molecules.
JUNIOR INSTITUTION OF ENGINEERS (at Royal Society of Arts), at 7.30.—Sir Henry George Lyons: Technical Museums and their Value to Engineers (Presidential Address).
INSTITUTE OF METALS (Sheffield Section) (in Non-Ferrous Section of Applied Science Department, University, Sheffield), at 7.30.—R. B. D. Barklie and A. E. Nicol: Studies in the Electrodeposition of Silver. Throwing Power. The Behaviour of Silver Anodes, with special reference to Blackening and its Prevention.

SATURDAY, DECEMBER 13.

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS, at 2.30.
ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir E. Denison Ross: Persia and the Persians (2): Art and Literature.

PUBLIC LECTURES.

SATURDAY, DECEMBER 6.

MATHEMATICAL ASSOCIATION (at Bedford College), at 3.—Dr. Cyril Norwood: The Value of Exactness (Presidential Address).
HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: Prehistoric Man in Minorca.

MONDAY, DECEMBER 8.

IMPERIAL COLLEGE, ROYAL SCHOOL OF MINES, at 5.30.—Dr. M. A. Hogan: Supports for Underground Workings in Coal Mines. (Succeeding Lectures on Dec. 9, 10, and 11.)
IMPERIAL COLLEGE OF SCIENCE (Royal College of Science), at 5.30.—Dr. T. M. Finlay: The Life of the Past (Swiney Lectures). (Succeeding Lectures on Dec. 10, 12, 15, 17, 19, Jan. 5, 7, 9, 12, 14, and 16.)

TUESDAY, DECEMBER 9.

KING'S COLLEGE, LONDON, at 11 A.M.—S. P. Turin: The Economic Geography of U.S.S.R.: Social and Economic Life.

WEDNESDAY, DECEMBER 10.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Sir Hubert Bond: The Prevention of Mental Illness.
ROYAL ANTHROPOLOGICAL INSTITUTE (in Portland Hall, Great Portland Street Extension of Regent Street Polytechnic, Little Titchfield Street), at 5.30.—Lord Raglan: Nilotic Tribes of the Anglo-Egyptian Sudan.
BELFAST MUSEUM AND ART GALLERY, at 8.—C. W. Harvey: Linen Damask: Historical Sketch.

THURSDAY, DECEMBER 11.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Dr. Marie C. Stopes: Positive and Negative Control of Conception in its various Technical Aspects.
NATIONAL INSTITUTE OF INDUSTRIAL PSYCHOLOGY (at London School of Economics), at 6.—Dr. W. J. Pinard: Tests of Character.—C. B. Fox: Industrial Psychology applied to the Blind.
BIRKBECK COLLEGE (Celebration of Foundation), at 8.15.—Sir Josiah Stamp: The Responsibility of Knowledge (Foundation Oration).

FRIDAY, DECEMBER 12.

INSTITUTE OF INDUSTRIAL ADMINISTRATION (at Institute of Hygiene, 28 Portland Place), at 5.30.—A. S. Comyns Carr: Education for Management, to be followed by a discussion.
SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Technical College, Cardiff), at 7.30.—H. Ll. Bassett: Nitrogen in Nature and Industry.

SATURDAY, DECEMBER 13.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—J. E. S. Dallas: Bird Life in and around London.

CONGRESSES AND EXHIBITION.

DECEMBER 5.

BRITISH INSTITUTE OF RADIOLOGY (at Central Hall, Westminster).
Friday, Dec. 5, 10.30 to 12.30.—Dr. H. A. Harris: The Growth of Bone as illustrated by Radiography.
Dr. D. Hunter: Changes in the Bones in Hyperparathyroidism and Hyperthyroidism.
At 4.30.—Dr. A. E. Barclay: The Danger of Specialisation (Silvanus Thompson Memorial Lecture).

DECEMBER 5.

INSTITUTION OF CHEMICAL ENGINEERS (at Chemical Society).—The Utilisation of Trade Wastes.
Friday, Dec. 5, at 10.30 A.M.—Dr. D. J. Lloyd: The Problem of Tannery Waste.
O. Wans: The Use of Wood Waste for Heating and Generation of Power.
At 2.30.—E. B. Busenburg: The Utilisation of Waste Rubber.
Prof. J. W. Hinchley: The Recovery of Metal from Waste Materials.

SATURDAY, DECEMBER 13, 1930.

No. 3189, Vol. 126]

Central Research Stations in Tropical Agriculture.

ONE of the features of the post-War administration of the tropical possessions of the British Empire is the increasing attention which is being paid to the application of science to agriculture. This is no longer the sole concern of the Colonial Office, as a number of new organisations, official and commercial, such as the Empire Marketing Board and the Empire Cotton Growing Corporation, are devoting every year large sums of money to research. The new movement gained considerably, both in impetus and in direction, when the Imperial Agricultural Research Conference met for the first time in London in 1927 (Nature, Oct. 29, 1927). One of the main recommendations of this Conference, as regards research, was a proposal for the establishment, as funds and staff permit, of a chain of central tropical and sub-tropical research stations which should, in the main, " confine themselves to long-range and wide-range investigations, or, in other words, should concentrate on (1) problems requiring more prolonged research than can normally be expected from the technical staff of any single administrative department, and (2) problems arising in more than one territory of the Empire towards the solution of which the comparative method may be expected to make an effective contribution ". On the relations between the proposed central stations and the local agricultural departments, the Conference laid down some general directions. The work of the central stations was expected to be developed as a reinforcement of the undertakings of the local agricultural departments and in no sense as a substitute for such activities. It was felt that such a policy would not only prevent friction but also would make overlapping impossible.

The recommendations of the Imperial Agricultural Research Conference were, with commendable promptitude, duly endorsed by the Committee on the Colonial Agricultural Service appointed by the Secretary of State for the Colonies, under the chairmanship of Lord Lovat. The first of the chain of Imperial Agricultural Research Stations, to be devoted solely to research, was started at Amani in East Africa in 1927. Steps were taken to develop and expand the estate and buildings taken over from the Germans at the armistice of 1918. The reports of the new station for the period Mar. 2, 1927, to Mar. 31, 1930—a little more than three years—have just been issued by the Colonial Office.*

* East African Agricultural Research Station, Amani. First Annual Report, 1928–29. Price 6*d*. net. Second Annual Report, 1929–30. Price 1*s*. net. London: His Majesty's Stationery Office, 1930. (Colonial, Nos. 50 and 51.)

These papers contain the fullest details of the history, purpose, and progress of the Amani Institute, and should be carefully studied, not only by all research workers concerned with tropical agriculture, but also by the administrative officers of the Colonial Services interested in the development of the regions entrusted to their care.

Although the original experiment station at Amani, founded by the Germans in 1902, passed through a period of neglect and vicissitude from November 1918 until March 1927 when the new scheme started, nevertheless the station generally was found to be in a surprisingly good condition when the present Director, Mr. W. Nowell, took over charge. The roads and plantations were in good order; the laboratories, library, and the botanical and entomological collections were well cared for. These circumstances have not only lightened the heavy work involved in the formation of a modern agricultural experiment station, but have also assisted the Director and the staff of the Institute in formulating a programme of work and in setting in motion a number of interesting investigations on such subjects as the rôle of shade trees in coffee cultivation, the nature and spread of the virus diseases of plants, the best methods for the study of soil erosion, and the maintenance of the fertility of tropical soils—a matter of the first importance in the future development of the African continent. One important extension of the research station has already been carried out. The neighbouring coffee estate of Kwamkoro has been taken over, connected with Amani by a motor road, and considerably developed. Plans for additional sub-stations at Tengeni and other places are being rapidly matured. The Amani Station is settling down to serious work and already the need for more workers is beginning to be felt.

As is inevitable in such undertakings, the new station has had to contend not only with local difficulties of a particularly trying nature, but also with a certain amount of adverse criticism. Much time and energy have had to be expended in improving the communications of the station itself and in making it accessible to visitors. The supply of local labour is scanty, as the climate of Amani is unpopular with the inhabitants of the lower levels. The experiment station has not yet been provided with a fully qualified medical officer and has to rely in all cases of emergency on the medical staff of the Universities' Mission at Tongwe. This is a great defect in organisation and one which should be dealt with by the authorities without delay. Adequate medical arrangements are not only imperative for the scientific workers and their families, but also would help in attracting a better supply of native labour. A good deal of local criticism, to the effect that Amani is not representative of East African conditions and that the results obtained cannot possibly apply to the six dependencies which contribute to its support, has had to be met. The Director points out that such criticisms would apply to any other site that could be selected, and that no alternative has yet been suggested with advantages which would offset the roads, buildings, equipment, and plantations which were already in existence at Amani in 1927 and which cost no less than £100,000 sterling.

A critical study of the Amani reports discloses one administrative weakness which is of considerable interest both to the scientific worker and also to the general public, namely, the incompatibility of long-range and wide-range research with the preparation of a detailed annual report. So little progress can be made in such work in twelve months that the submission of an annual report is almost ridiculous. Further, the practice leads t the waste of much valuable time, and also expo s the workers to the risk of uninformed comme and to undeserved criticism. It would seem th an important improvement in administration co be made, and that a reform long overdue co be carried out, if these annual reports could abolished altogether so far as research is concerne. If the workers at Amani could be asked to furnish instead a well-thought-out quinquennial review in which the purpose, equipment, progress, and cost of the station could be set out in clear and definite form, the present annual reports could be replace by a brief account of important administrative events, to which a statement of the annual receipts and expenditure, with the usual auditor's certificate, could be attached. This would provide fo any necessary administrative control of the station

From the point of view of the scientific investigator such an innovation has obvious advantages The workers overseas would then receive adequate protection, and they would be able to work ou their own salvation under conditions approximatin to those obtaining in the research centres of Grea Britain. The growing volume of annual reports now such an alarming feature of agricultural re search in the Empire, would be replaced by th five-yearly review, which would soon find a per manent place in the literature of the subject Further, such reviews would provide an effectiv documentation both for the Press and for th general public interested in the work, and woul

also prove invaluable as a basis for the deliberations of the Imperial Agricultural Research Conference, the next meeting of which will take place in Australia in 1932. A beginning in the direction indicated might be made next year. If quinquennial reviews of the various experiment stations in Australia and New Zealand for the period ending Mar. 31, 1931, could be prepared and circulated in time, visitors to the antipodes in 1932 would be provided with all the information they need for the study of the local experiment stations and of the results obtained. If other parts of the Empire adopted the same practice, the 1932 meeting of the Imperial Agricultural Research Conference would mark a distinct step in advance in providing that effective publicity which is now becoming so necessary in scientific work, not only for the workers themselves, but also for the public from whom the funds are ultimately derived.

(3) *The Spirit of Chemistry: an Introduction to Chemistry for Students of the Liberal Arts.* By Prof. Alexander Findlay. Pp. xvi + 480. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1930.) 10*s.* 6*d.*

AT the beginning of the present century there were few works on chemistry written in such a manner as to appeal to the intelligent layman; so that, in spite of such earlier works as Scoffern's "Chemistry No Mystery" (1839), chemistry remained a decided mystery to the average educated person. The text-books of the period were dressed in the trappings of an unimaginative formalism, and to layman and aspiring chemist alike the subject appeared to be far removed from the activities and interests of everyday life. Little attention was paid at that time to the historical evolution of the science or to the personalities of its creators. Such a system of instruction was capable of transforming a chemical enthusiast into a chemist, but it aroused no general interest in chemistry.

The texts of thirty years ago were designed originally for the training of chemists. In recent years, particularly since the War, there has been a growing recognition of the importance of chemistry as a subject of general education. As a result, it is no longer sufficient to provide treatises and courses for the training of the professional chemist: it has become necessary to consider the needs of the increasing number of pupils and students who require courses in what may be called cultural chemistry. Thus, the last few years have witnessed a striking popularisation of chemistry, and there is now available, particularly in the English language, a considerable variety of works on chemistry which may be read with pleasure and profit by the general student and by the educated layman. The publication of works of this kind has influenced in turn the character of the more formal text-books of chemistry. Altogether, the last decade has been characterised by a strong movement towards a brighter and more arresting presentation of chemical facts and theories, and at the same time there has been an equally marked growth of interest in the historical and humanistic aspects of chemistry.

(1) The three books under notice illustrate some of the main tendencies to be observed in the modern methods of presenting chemistry in the school, to the general reader, and to the lay student. In discussing methods of increasing the interest of pupils in school chemistry, an American writer (Collier, *Journal of Chemical Education*, 1930, 2141) states that "the foundation of a course is laboratory work. It is here the student at the start is given an opportunity to satisfy his curiosity and indulge in the interesting manipulation of chemical materials." Dr. Holmyard voices the same opinion in the preface to his little book: "Every opportunity has been taken to press into service those attractive phenomena in which chemistry is so rich; but if a boy or girl assimilates the fare provided, he or she will have acquired a knowledge of scientific method more difficult to appreciate than the beauty of the phenomena." Thus, already on p. 9, following an account of common laboratory apparatus, we find descriptions of an "astonishing experiment" with iodine and aluminium and an "exciting" chemical reaction with ammonium dichromate. We begin to realise, in fact, that "chemistry is a joyous adventure . . . rich in spoils". At appropriate intervals the narrative is projected against the background of history: when we visit Priestley, for example, we wear powdered wigs, travel in sedan chairs, and retail the current society gossip of Bath. Again, "our experiments with oxygen, simple as they are, represent the work of many different men,

of many different countries and ages ". From the chemical laboratory, Dr. Holmyard passes in succession to chemical changes, combustion, oxygen, hydrogen, formulæ and equations, water, acids, bases and salts, carbon dioxide, and air. The result is a very efficient and attractive little book with an excellent selection of illustrations.

We have often wondered, by the way, why Jan Ridd's vivid description of a " winkey " has never been commended to their pupils, in these days of *laissez-faire*, by writers of popular school texts, in dealing with the phenomenon of combustion. " This is the manner of a ' winkey ', which I here set down, lest child of mine, or grandchild, dare to make one on my premises ; if he does, I shall know the mark at once, and score it well upon him. . . . Anon, as he reads by that light his lesson, lifting his eyes now and then it may be, the fire of candle lays hold of the peter with a spluttering noise and a leaping. Then should the pupil seize his pen, and, regardless of the nib, stir bravely, and he will see a glow as of burning mountains, and a rich smoke, and sparks going merrily ; nor will it cease, if he stir wisely, and there be good store of peter, until the wood [of his desk] is devoured through, like the sinking of a well-shaft " (" Lorna Doone ", Chap. i.).

(2) Returning from Blackmore to our American writer, we read that little do the modern secondary students " care whether oxygen weighs 1·429 grams per liter, or that lead has a specific heat of 0·0305. Far more important to them is the fact that hydrogen used to be used in balloons and is now used to make oleomargarine and ammonia gas. Material must be presented in a modern way if it is going to stick and mean anything to the student in later life. The applications must be stressed rather than the actual physical and chemical properties of the various elements. . . . The uses of materials that affect the life of the student should be stressed rather than simply the building bricks of chemistry, namely, the study of the elements and their properties." We cannot accept these statements at their face value. The principle outlined, however acceptable to the chemical propagandist, should be applied with caution by the teacher of chemistry. This principle is the *leitmotif* of such works as Slosson's " Creative Chemistry ", and it is discernible in Prof. Deming's new book, which " is intended for the general reader who would like to know something of the manner in which organic chemistry grew and developed, and something of its contributions to the comforts and conveniences of modern life ".

Prof. Deming, however, has skirted the pitfall which has swallowed divers of his countrymen who have sought to popularise chemistry ; for, although he emphasises the material achievements of organic chemistry, he is not led thereby to shut his eyes to the importance of the theoretical foundations and the historical development of the science. He has, indeed, produced a proportioned and readable story of organic chemistry, written around the sub-titles : How the foundations were laid ; The organic chemical industries ; and, The chemical activities of living cells. The numerous illustrations include several original drawings which are intriguing if not always quite convincing in detail. We wonder, for example, whether Pasteur actually sorted his dextro- and lævo-rotatory crystals with the aid of two slips of paper labelled ' L ' and ' R '.

(3) Prof. Findlay's book is a comprehensive text for British and American " students of the liberal arts " who are studying chemistry " as an element of general culture rather than as a part of their professional or technical training . . . the purpose of the book is not so much to impart a detailed knowledge of a wide range of facts as to create a scientific spirit ; a spirit of toleration and of co-operation, of intellectual adventure and of intellectual honesty, which seeks ever to enlarge our knowledge of the external world and to found that knowledge, not on tradition or authority, but on a basis of ascertained fact." A mere glance at this admirably produced work, with its 480 pages, 88 figures, and numerous portraits and illustrations, gives an indication of the thorough manner in which the author has handled a task of considerable difficulty. The first three chapters deal with the aim and method of science and with the historical development of chemistry ; fundamental laws, atomic weights, atomic constitution, and the states of matter are next discussed. The historical setting which is a feature of the whole treatment assumes a prominent place in Chap. x., which treats of the atmosphere and of combustion. The ensuing discussion leads naturally to a consideration of matter and energy and of fuels and illuminants. Without enumerating further headings, it may be said that the book constitutes a facile and consecutive narrative embracing and illustrating the fundamental principles, materials, and achievements of chemistry, inorganic, physical, and organic.

In reading this work, we were impressed particularly by its logical and balanced treatment of so wide a field, its apposite quotations, its historical background, and in general by its scholarly and literary presentation of a scientific theme. The book contains several illustrations of historical

interest which are not readily accessible elsewhere; we may here mention Cruikshank's interesting caricatures concerning the introduction of coal gas and the effects of laughing gas. As an example of the author's attention to detail, we commend his footnote on van Ostade's painting of "The Alchemist", incorporating an interesting observation which will e new to many admirers of this well-known picture: "On the sheet of paper lying on the floor he artist, with ironic humour, has painted the words, *oleum et operam perdis*, thou labourest in ain".

From these comments it will be realised that the book is not of the sugar-coated variety, which aims at sparing the reader all thought and effort and nds by giving him at the best a superficial smattering of the subject. It is, on the contrary, a sound and carefully planned treatment of chemistry for the non-professional student, framed withal in a ery attractive and readable form. In evolving it, he author has carried out a noteworthy experiment in chemical exposition, and, in our opinion, has mply fulfilled the purpose indicated in his preface. Ve hope that in due course he may have an opportunity of expounding, in a complementary publication, his views concerning the practical work appropriate for the students for whom this book has been ritten.

JOHN READ.

Older Tectonic Geology of North-Western Europe.

Geologie von Europa. Von Prof. Dr. Serge von Bubnoff. (*Geologie der Erde*, herausgegeben von Prof. Dr. Erich Krenkel.) Band 2: *Das ausseralpine Westeuropa.* Teil 1: *Kaledoniden und Varisciden.* Pp. xii + 691 + 4 Tafeln. (Berlin: Gebrüder Borntraeger, 1930.) 49·50 gold marks.

THE fourth of the volumes of Prof. Krenkel's monumental work, "Geologie der Erde", is the first part of the second volume of Prof. von Bubnoff's "Geologie von Europa" and is a valuable monograph on the older geology of the extra-Alpine regions of north-western Europe. It is entitled the "Kaledoniden und Varisciden" and dopts the term Caledonids in the extended sense for all the pre-Permian mountains and not only for those of the Middle Palæozoic. That extension involves a double use of the word and makes it applicable to a greater range in time than when for one of the main orogenic epochs—the "Kaledonische Discordanz" (p. 607).

The volume is occupied mainly by a description of the pre-Permian and, for some areas, also of the Lower Permian geology of north-western Europe. The first two chapters deal with the Caledonids of Norway and some parts of Sweden, and with the British Caledonids: it summarises the Palæozoic geology of the British Isles except of southern Ireland, Cornwall, and part of Devon, which are grouped tectonically with north-western France as part of Armorica. The further chapters deal with Brittany, the Central Plateau of France, the Ardennes and the Middle Rhine, and the mountain blocks beside the Upper Rhine, comprising the Vosges, the Black Forest, and some of the hilly uplands of south-western Germany, including the Spessart and the Odenwald; further chapters describe the Harz Mountains, the Bohemian mass and its bordering mountains—the Sudetes on the north-east and the Thuringer Wald on the west. The last chapters are on the older rocks of Poland, which are less well known as the Sventokrizer than under their old name of the Lyssa Gora. The final chapter discusses the influence of these old mountain remnants on the structure of western Europe.

Each chapter gives an account of the pre-Palæozoic and Palæozoic stratigraphy of the area, and of its structure and economic geology, with a bibliography which is especially useful as it gives reference mainly to the later literature. The book is not only a compendium but also a critical re-examination of the main evidence and states the conclusions regarding various questions of stratigraphical classification by an authority whose knowledge of European stratigraphy is unusually wide. The stratigraphical successions and their correlation are clearly stated in four large folding tables. On the controverted question of the Silurian-Devonian boundary the author divides the Downtonian into two and places the upper division, including the Ludlow Bone Bed and the beds above it, in the Devonian; but as he correlates them with the Foreland Sandstones and the Dartmouth Slates, and includes the Whitcliff Flags (which he calls the Whitecliff) in the Downtonian, he does not take quite the same ground as those British geologists who extend the Devonian down to the Ludlow Bone Bed.

The term Silurian is not much used, as according to the author it includes everything between the Cambrian and Devonian, and thus the rocks which British geologists regard as the Silurian he calls Gotlandian.

In dealing with the claims for extensive rock metamorphism by the Variscan movements, the author notes but does not accept the view of the upper Palæozoic age of the schists and gneisses

which form the dominant constituents in the Moldavian-Danubian belt; and in re-affirming the pre-Cambrian age of the granulites of Saxony he notes the conclusion of Pietzsch (1922) that the quartzites and arkose of middle Saxony, which have been generally classified as Lower Carboniferous (Culm.), are also pre-Cambrian.

Each chapter concludes with an interesting account of the economic geology; the author notes that of the coal of Europe the British shelf contains 11·2 per cent, as compared with 87 per cent in the fields associated with the Variscan blocks, mainly in Germany and Upper Silesia. As regards the disputed genesis of the Rammelsberg ore-body, he quotes the recent conclusion of Frebold that it is of sedimentary origin but has undergone fundamental dynamic metamorphism; this view takes up a position intermediate between the old syngenetic and the metasomatic theories. As the book includes only rocks up to the top of the Rotliegende, the Kupferschiefer which lies upon that horizon is not considered.

British geologists naturally turn first to the British section, which is the least complete. The author makes a heroic attempt to deal with the problems of the Scottish Highlands and gives summaries of the various classifications. Prof. von Bubnoff appears to favour the views of Frodin, according to whom the Scottish metamorphic rocks conform with the conclusions of those Scandinavian geologists who accept the Palæozoic age of large areas of their crystalline schists. The book reproduces a sketch map by Frodin that represents the schists of the Scottish Highlands as the metamorphosed representatives of the Ordovician and Silurian rocks of the Southern Uplands. The evidence from Ireland appears, however, to negative that view conclusively.

There are occasional verbal slips in the British section, such as 'in Lancaster' instead of Lancashire, and 'scherts' for cherts, while 'Jorkian' is unfamiliar for Yorkian, and 'Canal' for English Channel. The volume is large and expensive, but it is illustrated by 201 excellent figures, which are mostly sketch maps and sections, with theoretical diagrams to summarise the author's interpretation of the epeirogenic movements that controlled the depth and character of the deposits. Unfortunately, the map of the German Variscan Mountains, which like many others is after Kosmat, has been printed upside down in reference to the legend, so that use of this instructive figure requires constant inversion of the book to compare its elaborate shading with the explanation.

J. W. G.

Bird Studies.

(1) *British Birds.* By F. B. Kirkman and F. C. R. Jourdain. Pp. xvi + 184 + 202 plates. (London: T. C. and E. C. Jack, Ltd., 1930.) 21*s.* net.

(2) *The Birds of Tropical West Africa: with Special Reference to those of the Gambia, Sierra Leone, the Gold Coast and Nigeria.* By D. A. Bannerman. Published under the authority of the Secretary of State for the Colonies. Vol. I. Pp. lxxv + 376 + 10 plates. (London: The Crown Agents for the Colonies, 1930.) 22*s.* 6*d.* net.

(1) THE shelf of works of reference on British birds is now so crowded that a new book must have special merit to be welcome as an addition. This requirement is well fulfilled by the volume which comes from two well-known authorities, Mr Kirkman and Mr. Jourdain, with two hundre[d] coloured plates by a group of artists Winifr[ed] Austen, G. E. Collins, H. Goodchild, H. Grönvol[d], G. E. Lodge, and A. W. Seaby. The plates, amo[ng] the best of their kind both for utility and for pi[c]torial merit, were published nearly twenty yea[rs] ago in the monumental "British Bird Book" edit[ed] by Mr. Kirkman. Their reappearance here, ex[cel]lently reproduced, in a single volume of moder[ate] size, will be convenient even to possessors of t[he] larger work, and will also bring them within t[he] reach of a wider public.

The text is new and adequate to the purpose. [It] consists of a brief account of the appearance, ran[ge] and habitat, nest and eggs, food, and usual notes, [of] each species, conveniently placed to face the cor[re]sponding plate. The information given is accur[ate] and up-to-date within its scope, but no gene[ral] description of habits is attempted. There is te[xt] also for the rarer species which are not figured, a[nd] at the end there is a series of plates showing the eggs of British breeding birds. Altogether, most excellent value for a guinea; but the alphabetical table of contents has not been revised with sufficient care.

(2) In writing a book on the birds of West Africa, Mr. Bannerman is breaking practically new ground, but he has immediately set a high standard. The bulk of the volume consists of a systematic account of the species, giving for each the distinguishing characters, particulars of range, and a summary of the information available as to habits. The volume before us covers only eight natural orders, and, with the Passeres among those still to be treated, several further volumes are to be expected. It is to be hoped that, despite the immense labour that must be involved, the author will be able to

complete the work in the near future and so let it achieve its full measure of utility.

That the work will be most useful cannot be doubted. Mr. Bannerman has aimed not only at setting down existing information, in which there are necessarily many gaps, but also at facilitating further additions to knowledge of the subject. At present, many potential observers in our West African colonies are hampered by the lack of means for identification, and opportunities for gaining valuable information on habits and economic status are thus wasted. Mr. Bannerman has therefore supplemented the account and figures of the species by the addition of two useful 'keys', one pictorial and the other verbal, to assist the observer to classify and identify the birds. The practical ortance of the subject, from an economic point iew, is encouragingly recognised by the financial port to publication given by the West African ernments, and by the preface contributed by the tary of State for the Colonies.

Matter of much general interest is to be found in preliminary chapter in which Mr. Bannerman y discusses the relation of vegetation belts to the ribution of bird life. The region includes belts desert, either wholly barren or with the scant haran vegetation; of savanna, either of the orn-scrub type or grass-woodland; and of rain-rest; while smaller areas show the mangrove, the eshwater swamp, or the 'montane' types of egetation. Each kind of area has its character-tic bird association. The virgin forest, with its closed canopy' above and its twilit, almost im-enetrable depths, has indeed two distinct associa-ons, the hornbills and parrots of the tree-tops being lmost in a different world from the guinea-fowl and round-doves that walk below: a third type of vifauna is found in secondary forest.

Several general points stand out. The vegetation belts stretch mainly right across the continent, so that latitude makes more difference to bird-life than longitude. Then there is the similarity of the avifaunas of the various widely separated mountain ranges. Striking, too, is the statement that equatorial forest constitutes a greater barrier even than utter desert to the spread of native species or to the passage of northern migrants: the extent and continuity of the forest zone in the west as compared with the east, indeed, seems to be one of the chief factors influencing routes of bird-migration in Africa. Truly, as Mr. Bannerman says, "Naturalists who find themselves in West Africa need not allow time to weigh heavily on their hands!" His book will certainly help to direct their activities.

Our Bookshelf.

Handbuch der Pharmakognosie. Herausgegeben von A. Tschirch. Zweite, erweiterte Auflage. Lieferung 1. Pp. 112. (Leipzig: Bernhard Tauchnitz, 1930.) 8 gold marks.

PROF. TSCHIRCH'S handbook of pharmacognosy, the publication of which was commenced in 1909, has proved to be such a mine of information to all interested in crude drugs that the appearance of a new edition will undoubtedly meet with general approval. In the course of the twenty-one years that have elapsed since the issue of the first part, the study of drugs has been so vigorously prosecuted and with such important results that many additions and corrections were necessary; in fact the early parts were in many respects out-of-date. It is obvious that the task of revising a work comprising some 4000 pages and embracing pharmacognosy, botany, chemistry, and several other sciences, was an almost impossible task for a single individual, and the news that the author has obtained the collaboration of other experts for certain sections of the book will be universally welcomed. It is expected that the revision will be completed in about three years and that the size of the work will be increased by about 1000 pages.

On comparing the first part now published with the corresponding part of the first edition, it is evident that this revision is being very carefully carried out and that much new matter is being incorporated. Entirely new, for example, is the truly remarkable list of medicinal plants used in the allopathic and homœopathic treatment of disease. The section on the collection and cultivation of medicinal plants has been entrusted to Dr. W. Himmelbaur, who, with Prof. de Graaff and others, has contributed so much to the revival of interest in this department of pharmacognosy. In this section numerous additional maps and illustrations have been incorporated. Quite apart from the information given in the text, the very complete bibliography will be invaluable to research workers; for example, in the list of plants grown in East Prussia the number of references has been more then trebled. The utility of microchemical reactions, of microsublimation and of examination by means of the quartz lamp, all methods of comparatively recent introduction, receive adequate attention, which serves to show the thoroughness with which the revision is being carried out. The author and his collaborators are to be congratulated upon the results of their work.

A Narrative History of Aviation. By John Goldstrom. Pp. xii + 319 + 32 plates. (New York: The Macmillan Co., 1930.) 17*s*. net.

"A NARRATIVE History of Aviation" is a title both bold and comprehensive enough to suit the most captious person. Unfortunately, this book falls far short of justifying either of these adjectives. One of the most essential requirements of the historian is a sense of proportion, unless he is producing an encyclopædic production continuing to many volumes. 'Scissors and paste'

may have legitimate functions, but they are not for the writer of history, as their use means sacrificing whole batches of facts contained in the lopped-off portions. 'Precis' is rather his refuge.

The author's extensive use of inverted commas admits that his book is principally culled from other sources, as indeed any history must be; but his editing of the subject matter at his disposal is out of proportion. He states that "Countless centuries of heroic failure . . . must be summarized in a chapter", and then proceeds to devote whole chapters to such subjects as "Women in Aviation" and "The American Air Mail". Such things have occurred only in the last few years, and are then merely episodes.

Lack of perspective is marked in the author's choice of subjects and illustrations. American aeronautics receives a far larger proportion of pages than its share in the world's aeronautical history merits. This is understandable in a book written and published in the U.S.A. National pride is wholly admirable, but it is out of place under the title that this book carries. The book goes even further than this in publishing a photograph of the author with a delivery of U.S.A. air mail. Surely the decision as to the historical importance of that could better have been left to posterity.

Its limitations are redeemed, to a certain extent, by an extensive bibliography, which mentions other sources of historical knowledge, but this is by no means up-to-date, especially with regard to European publications.

As a collection of short historical studies the book provides instructive and amusing reading. It should never have been submitted to the world of serious technical history under so ambitious a title. *Coram non judice.*

The Electric Wiring of Buildings. By F. Charles Raphael. Pp. x + 258. (London: Sir Isaac Pitman and Sons, Ltd., 1930.) 10*s*. 6*d*. net.

THERE are many practical hints in this little book which appeal to common sense, although from the point of view of the ordinary electric wireman they are quite unorthodox. The author points out, for example, that the wiring of many houses is spoilt by placing the wall sockets indiscriminately without regard to the position or character of the apparatus to be connected to them. It is as absurd to place the wall socket for a floor standard lamp or vacuum cleaner three feet from the floor as to put one for a table standard at floor level, if the table is to be against the wall. It is quite right to put the wall socket for an electric fire on the skirting, but the almost universal practice of placing the switch there as well is foolish. It is true that this saves the cost of a wood block and a few feet of wire, but this saving of a shilling or two on capital cost is only effected by compelling people for ever afterwards to stoop down to the floor when they want to switch on or off the electric fire. The book finishes up with a useful chapter on bells, telephones, fire alarms, and radio. As a rule, it is advisable to have all these kinds of wiring done before the building is actually furnished. In the case of telephones, however, it is sometimes difficult to tell which is the most suitable place for them before the house is furnished, and hence surface wiring is very frequently used for telephone work. The proper wiring of all electric radio receiving sets deserves special care. Unless the Institution of Electrical Engineers Wiring Regulations, published in June 1928, be followed, there may be danger from shock or fire.

Calculus. By Prof. Egbert J. Miles and James S. Mikesh. Pp. xiii + 638. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1930.) 18*s*. 9*d*. net.

To the student reading natural science as his main object, this book will have a definite appeal. A considerable number of well-chosen examples of the use of the derivative in hydrostatics and in pumping machines is an unusual feature. The authors state that, in the earlier part of the book at least, they purposely reject the delta notation, with the object of making the transition from conventional algebra easier for the average reader. This seems a somewhat needless scruple, for it only means greater difficulty at a later stage when the methods of the operator calculus have to be mastered: in these days this branch of the subject is finding new applications.

Nevertheless, one gets the impression that the authors intended to produce their work, in the first place, for the pure mathematician rather than for the physicist or engineer. If this is so, they will be less successful, for the treatment throughout tends to be more careful of the reader's supposed attainments at each stage than is quite compatible with perfect rigour.

That the volume will prove helpful in a variety of ways is certain: a special word of commendation is due to the publishers for the excellence of the graphs, which really do enhance the value of the book.

Optical Rotatory Power: a General Discussion held by the Faraday Society, April 1930. Pp. iv + 265-461. (London: The Faraday Society, 1930.) 10*s*. 6*d*.

THE reports of discussions held by the Faraday Society are always welcome. Naturally, a series of individual contributions lacks unity of aim to some extent, but a certain freshness of outlook results, which is all to the good. The meeting itself has been described at some length in our columns (NATURE, May 17, 1930, p. 762); little therefore remains but to direct attention to the appearance of the papers in book form.

The memoirs by Dr. Temple, Dr. Kuhn, and Prof. Ewald contain the vital points at issue; probably, however, in no case has the last word been said on a subject unusually intractable. Right- and left-handed forms of active molecules certainly possess stability, and yet the new mechanics has no solution of these facts to offer. Workers will be grateful, none the less, for the results of a decidedly interesting conference.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Constitution of Tungsten.

AFTER many earlier unsuccessful attempts, I have now obtained the mass-spectrum of tungsten. As in the cases of the lighter members of the same group, chromium and molybdenum, success was made possible by the preparation of the volatile carbonyl, $W(CO)_6$, by Dr. A. v. Grosse, of Berlin. It was to be expected from the greater atomic weight that the photographic effect would be feeble, and only by means of very sensitive plates were lines of satisfactory intensity obtained.

Tungsten proves to have four isotopes, of which the strongest two give lines of practically identical intensity. The mass numbers and provisional relative abundances are as follows:

Mass number . .	182	183	184	186
Percentage abundance	22·6	17·2	30·1	30·0

The packing fraction has not been measured with accuracy, but the position of the lines relative to those of mercury proves their correspondence to whole numbers within one part in two thousand, and the packing fraction curve also suggests a zero value. Adopting this, we get for the atomic weight on the chemical scale 183·96, in good agreement with the value 184·0 now in use.

The X-Ray Interpretation of the Structure and Elastic Properties of Hair Keratin.

RECENT experiments,[1] carried out for the most part on human hair and various types of sheep's wool, have shown that animal hairs can give rise to two X-ray 'fibre photographs' according as the hairs are unstretched or stretched, and that the change from one photograph to the other corresponds to a reversible transformation between two forms of the keratin complex. Hair rapidly recovers its original length on wetting after removal of the stretching force, and either of the two possible photographs may be produced at will an indefinite number of times. Both are typical 'fibre photographs' in the sense that they arise from crystallites or pseudo-crystallites of which the average length along the fibre axis is much larger than the average thickness, and which are almost certainly built up in a rather imperfect manner of molecular chains—what Meyer and Mark [2] have called *Hauptvalenzketten*—running roughly parallel to the fibre axis.

Hair photographs are much poorer in reflections than are those of vegetable fibres, but it is clear that the α-keratin, that is, the unstretched form, is characterised by a very marked periodicity of 5·15 A. along the fibre axis and two chief side-spacings of 9·8 A. and 27 A. (? mean value), respectively; while the β-keratin, the stretched form, shows a strong periodicity of 3·4 A. along the fibre axis in combination with side-spacings of 9·8 A. and 4·65 A., of which the latter is at least a second-order reflection. The β-form becomes apparent in the photographs at extensions of about 25 per cent and continues to increase, while the α-form fades, up to the breaking extension in cold water, which is rarely above 70 per cent. Under the action of steam, hair may be stretched perhaps still another 30 per cent, but no other fundamentally new X-ray photograph is produced. The question is thus immediately raised as to what is the significance of a crystallographically measurable transformation interpolated between two regions of similar extent where no change of a comparable order, so far as X-ray photographs show, can be detected.

The elastic properties of hair present a complex problem in molecular mechanics which up to the present has resisted all efforts at a satisfactory explanation, either qualitative or quantitative. Space forbids a detailed discussion here of the almost bewildering series of changes that have been observed, and we shall merely state what now, after a close examination of the X-ray and general physical and chemical data, appear to be the most fundamental.

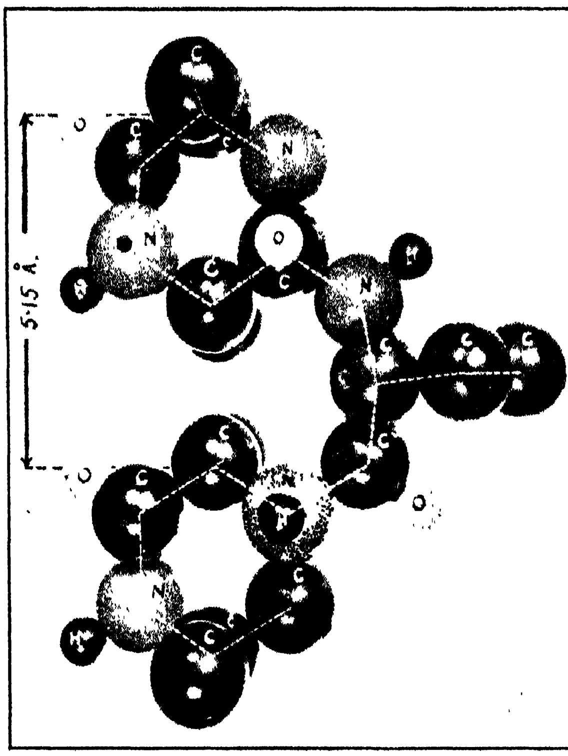

FIG. 1.

(1) Hair in cold water may be stretched about twice as far, and hair in steam about three times as far, as hair which is perfectly dry. (2) On the average, hair may be stretched (in steam) to about twice its original length without rupture. (3) By suitable treatment with steam the discontinuities in the load/extension curve may be permanently smoothed out, the original zero is lost, so that the hair may be even contracted by as much as one-third of its original length, and elasticity of form may be demonstrated *in cold water* over a range of extensions from −30 per cent to +100 per cent. (4) The elastic behaviour in steam is complicated by 'temporary setting' of the elastic chain and ultimately by a 'permanent setting' of that part which gives rise to the fibre photograph. (5) That part of the elastic chain which is revealed by X-rays acts *in series* with the preceding and subsequent changes.

On the basis of these properties and the X-ray data, it is now possible to put forward a 'skeleton' of the keratin complex which gives a quantitative interpretation of the fundamentals, and may later lead to a correct solution of the details. The skeleton model is shown in Fig. 1. It is simply a peptide chain folded into a series of hexagons, with the precise

nature of the side links as yet undetermined. Its most important features may be summarised as follows :— (1) It explains why the main periodicity (5·15 A.) in unstretched hair corresponds so closely with that which has already been observed in cellulose, chitin, etc., in which the hexagonal glucose residues are linked together by oxygens. (2) When once the side links are freed, it permits an extension from 5·15 A. to a simple zigzag chain of length $3 \times 3{\cdot}4$ A., that is, 98 per cent, and also allows for possible contraction below the original length, without altering the interatomic distances and the angles between the bonds. (3) It explains why natural silk does not show the long-range elasticity of hair, since it is for the most part already in the extended state,[3] with a chief periodicity of 3·5 A. We may now hope to understand why it is that the photographs of β-hair and silk are so much alike. (4) It gives a first picture of the 'lubricating action' of water and steam on the chain, since X-rays show that the direction of attack is perpendicular to the hexagons and that this spacing remains unchanged on stretching. Furthermore, it now seems clear that the new spacing, 4·65 A., is related to the old by the equation $27/(3 \times 4{\cdot}65)$ $3 \times 3{\cdot}4/5{\cdot}15$ (very nearly), that is, the transformation elongation takes place directly at the expense of the larger of the two side-spacings. In the particular arrangement of the hexagons shown in the model, the side chains occur in pairs on each face, and it may well be that the action of water is the opening-up of an internal anhydride between such adjacent side chains. (5) The chain being built up of a succession of ring systems stabilised and linked together in some way by side chains of the various amino acids, we have here an explanation of the well-known resistance of the keratins to solvents and enzyme action. In addition, each hexagon is effectively a diketo-piperazine ring, an interesting point in view of the evidence which has been brought forward by Abderhalden and Komm[4] that such groups pre-exist in the protein molecule. It may also throw light on the stimulating researches of Troensegaard.[5] (6) There are three principal ways of constructing the model, according to which group lies at the apex of a hexagon. It thus affords an explanation of the apportioning of a transformation involving a 100 per cent elongation into three approximately equal regions which may be opened up in turn under the influence of water and temperature and other reagents. The modification shown in the model must be ascribed to the crystalline phase, since it would, alone of the three, be expected to give rise to a strong reflection at 5·15 A., as in the α-photograph.

A detailed account of the above work will be published shortly.

Electrode Potentials in Air-free Electrolyte.

THE following somewhat wide problem is of very considerable practical importance.

What potential will a metal surface assume when it is immersed in a salt solution which contains none of its own ions, under different conditions of aeration, pH and salt concentration, and what conditions control this potential? Such practical matters as corrosion, and in general the behaviour of metal surfaces in ordinary circumstances, depend on the answer.

Work was undertaken in this laboratory some time ago with the view of discovering the controlling factors in connexion with the above problem, for though a great deal of special experimental data is available, very little systematic knowledge seems to exist regarding the potential of a metal in such a solution. It was recognised that the problem must be attacked in two sections, first, with the solution completely air-free, as an oxide film in most cases greatly modifies the electrode potential, and secondly, in the presence of air.

It is felt to be worth while at this stage to review the conclusions so far arrived at in air-free conditions. They are drawn from a certain amount of unpublished work, together with some that has been published. The conclusions are arrived at principally as the result of a study of the three metals iron, zinc, and cadmium, although rough experiments have been made with other metals. They are as follows:

(i.) *A steady reproducible potential can be obtained in air-free solution.* When an electronegative metal, previously exposed for some time to air, is immersed for some hours in an air-free electrolyte which is not strongly alkaline, it attains a steady reproducible potential, even in the absence of its own ions in the body of the electrolyte, and even when its salt with the anion of the electrolyte is soluble. Exceptions arise in the case of metals made strongly passive by exposure to air, such as aluminium and stainless steel.

(ii.) *Dependence of reproducible potential on pH.* When the electrode has a low hydrogen overvoltage, this reproducible potential is determined by the pH of the solution and varies with it. As might be expected, it is independent of the pH, except in concentrated acid, when the electrode has an overvoltage high compared with its deposition potential, like cadmium or zinc. It must be remembered that this discussion applies to rigidly air-free conditions, and in such a case with the electronegative metals investigated, the overvoltage of which is high, there was no indication of behaviour as metal metal oxide electrodes. Iron, on the other hand, when the electrolyte was alkaline and the electrode was probably not behaving directly as a hydrogen electrode, did give evidence of acting as a metal-metal oxide electrode, and variation of potential with pH still took place.

(iii.) *Effect of anion concentration.* The concentration of the anion in the solution does not affect the electrode potential where this is controlled by pH, but it does do so to some extent where such is not the case; for example, the potential of a pure cadmium electrode is about 70 millivolts more positive in $N/2000$ normal potassium chloride than it is in normal potassium chloride. In $N/2000$ potassium chloride, the electrode is at a potential corresponding to a concentration of about $N/2000$ cadmium ions. It appears probable that there is a thin layer of ions of the metal of the electrode in close contact with its surface, the concentration of the layer being determined by the anion concentration in the body of the solution.

(iv.) *Potential not determined by electrode metal ions in body of solution.* In the case of a metal having a low hydrogen overvoltage, the potential as expected is much more positive than can be accounted for by metal ions which have come into the electrolyte by solution from the electrode itself or from an oxide film.

But this was found to be the case with metals of high overvoltage as well; for example, when the potential of a cadmium electrode was such that the

concentration of its ions according to the Nernst theory should have been $N/10{,}000$, it was actually [illegible] by direct chemical analysis to be less than $N/100{,}000$.

Attempted generalisation of whole position. When there is no sensible concentration of the ions of a metal electrode in a solution, and the electrode is not covered by an oxide film, its potential is determined by pH if its hydrogen overvoltage is positive to the deposition potential which it would have in a solution of the order $N/1000$ in its own ions. When this is not the case, the potential is controlled by anion concentration, probably acting through a film of electrolyte in contact with the metal with a concentration of electrode metal ions of the order of $N/10{,}000$.

It is hoped later to investigate further the reason for the reproducible potential attained by high overvoltage metals, but for the present it is intended to study aerated conditions, and for this reason it has [b]een thought well to summarise previous work in [w]hich air was strictly excluded.

Our best thanks are due to the Commonwealth [C]ouncil for Scientific and Industrial Research [A]ustralia), which, by a generous grant, has made this [wo]rk possible.

Raman Spectra of Pinene.

IN a series of researches to be published in full [sh]ortly on the Raman spectra of *d*- and *l*-pinene [in] the liquid condition, we have observed near the [li]ne $\nu = 23257$ (corresponding to the Raman $\nu = 1454$ [ex]cited by the line λ 404·6 of mercury) a series of

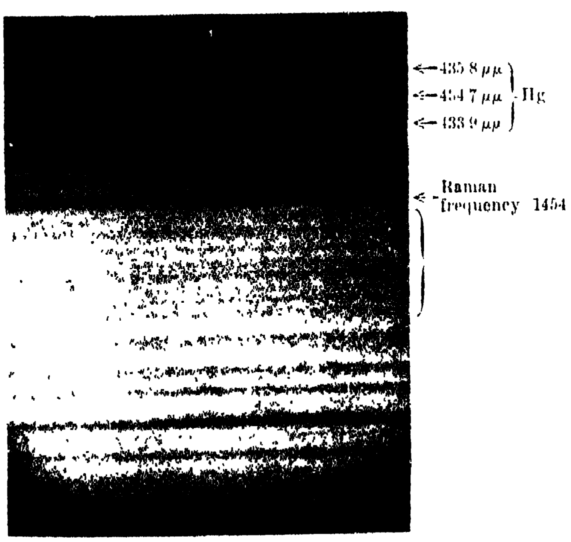

FIG. 1.—Raman spectrum of pinene.

[e]ight lines, very weak, sensibly at the same distance, [a]nd the distances of which from the Raman line [a]bove mentioned can be represented to a good ap[p]roximation by the relation $\Delta\nu = B(4m+4)$,[1] which, [a]s is well known, corresponds to the series of Raman [f]requencies of rotation relative to the rotator with [f]ixed axis. By putting $B = 6{\cdot}15$, the mean differ[e]nces between calculated and observed values amount [t]o $\pm 0{\cdot}017$ per cent. The value of m should correspond to the even series, namely, 2, 4, 6, 8, etc. Supposing the rotator composed by two atoms of H of one CH_2 rotating round the carbon atom (considering that the Raman frequency $\nu = 1454$ is attributed [2] to the transverse oscillations of the two H atoms in the group CH_2), we calculate, from the value of B, that the distance between the atoms of hydrogen and carbon in the CH_2 group is $1{\cdot}16 \times 10^{-8}$ cm., in good accordance with the values published by Mecke,[3] namely, $1{\cdot}13 \times 10^{-8}$ cm. In view, however, of the difficulty of obtaining good vibration and rotation spectra in liquids with complex molecules, we merely direct attention to the coincidence observed (working with a spectrograph with small dispersion); we intend to repeat the work with higher dispersion, before giving a definite interpretation to the results.

The Wave-length of X-Rays.

IT is well known that determinations of the wave-length, λ, of X-ray spectral lines, which have recently been made by means of line gratings, do not agree with those found by crystals, the crystal values being 0·1 to 0·3 per cent less than the line grating values. In this use of line gratings the angles of incidence and diffraction have been small and have proved difficult to measure, but the accuracy attained in some of the observations of λ (for example, that of Backlin for aluminium $K\alpha$) is probably not less than 1 in 1000. In the crystal method, relations of the form $n\lambda = 2d \sin\theta$ and $d^3 = eM/\rho F$ (e, electronic charge; F, faraday; M, molecular mass; and ρ the density of the crystal) are used to find λ, and the angle of reflection θ has been measured with high accuracy. Since M, ρ, and F are subject to smaller errors than e, the disagreement in the values of λ found by the two methods is usually attributed to an error of 0·3 to 0·9 per cent in the accepted value of e. If the precision of the grating method could be increased, these relations would be available to find the electronic charge more accurately than it is known at present.

The precision with which the wave-lengths of the lines of the spectrum in the optical region are known has enabled many problems in physics to be solved, and it is probable that improvement in the absolute accuracy of X-ray wave-lengths will prove of similar value.

In X-ray spectrometry up to the present the grating appears always to have been used to measure wave-lengths not relatively but absolutely, and this involves the precise determination of small angles. In the light of experiments we have performed, it would appear to be possible to use Rowland's method of the coincidence of lines in different orders of the grating spectrum over the whole spectral region from the optical to X-rays. It should be noted that the absolute errors in Rowland's wave-length tables do not imply any failure of this method, and from Kayser's comparison of Rowland's values of λ with interferometer values it appears that the method has a precision of one in a million in relative determinations in the optical region.

One of the difficulties to be anticipated in extending the methods to the X-ray region is that, owing to the small angle at which X-rays are reflected at the surface of a solid, the method would fail in that region. Using

a plane glass grating of 10,800 lines to the inch, a vacuum spectrograph, and X-ray tube with a graphite target in the same vacuum, we find that the K line of carbon can be photographed from the 18th negative order to the 13th positive order, or over a range of $n\lambda$ from 0 A. to 810 A. In this way, using a small dispersion, the carbon K line has been compared with the copper $L\alpha$ and Ll lines in their second and fourth orders, the wave-lengths 44·7 A. and 44·8 A. being obtained for the carbon line relative to 13·32 A. for the copper $L\alpha$ line. The approximate coincidence of different orders has also been used to compare the wave-length of the first order K lines of aluminium lines reflected from a sugar crystal with the wave-length of the $K\alpha_1\alpha_2$ copper lines in the 5th and 6th orders. We find Al $K\alpha_1\alpha_2$ 8·315 A. relative to Cu $K\alpha_1\alpha_2$ = 1·5392 A.

Structure of Hydrogen Sulphide, Hydrogen Selenide, and Nitrogen Dioxide at Liquid Air Temperature.

IN connexion with previous determinations of the structure of solid α-nitrogen [1] and of solid carbon monoxide, we have during last year carried out a structure analysis of solid hydrogen sulphide, hydrogen selenide, and nitrogen dioxide by means of powder diagrams obtained with an apparatus described in a previous paper. A more complete description of the results will appear elsewhere, but I want here briefly to state some of the principal results.

Solid hydrogen sulphide and selenide are both isomorphic with a cubic elementary cell containing four molecules. The sulphur and selenium atoms are arranged in a face-centred lattice. If the hydrogen atoms are to be given definite positions in the lattice, a discussion of all possible arrangements leads to the result that the atoms of a molecule must be situated on a straight line.

The most probable space group would be T^4, if the molecule is asymmetric, and $T^6{}_2$, if it is symmetric. For the side of the cell (a) and the density (ρ) we found for hydrogen sulphide, a = 5·76 A.; ρ = 1·17; for hydrogen selenide, a = 6·10 A.; ρ = 2·34.

These determinations were finished in July this year.

Solid nitrogen dioxide has also a cubical structure, but much more complicated than that of hydrogen sulphide and selenide.

The side of the elementary cell (a) is 7·77 A. The density (ρ) of solid nitrogen dioxide was determined separately to be 1·93, which gives six molecules in the cell. All lines observed fulfil the condition : Σh = an even number, which means that the lattice may be regarded as composed of cube centred lattices.

After having discussed all space groups fulfilling these conditions, we find T^5 to be the only one possible. This space group gives one parameter for the nitrogen atom, and three parameters for the oxygen atoms. By making certain assumptions regarding the limits for the nearest approach of the atoms, we have succeeded in determining the parameters so as to give a remarkably good agreement between observed and calculated intensities.

A more detailed description of this rather complicated structure will be reserved for a subsequent paper.

Isomorphism and Chemical Homology.

IN April 1929 I published a paper on "Monofluorphosphoric Acid and the Similarity of its Salts to the Sulphates" in the *Berichte der Deutschen Chemischen Gesellschaft*, p. 793. I stated that I had succeeded in preparing the monofluorphosphates, which I described in detail and also that the ion PO_3F'' shows all the properties of SO_4''. I pointed out that the salts of monofluorphosphoric acid resemble completely the salts of sulphuric acid and that the crystallographic investigation of the new salts was being carried out. I considered that the reasons for the similarity of chemical properties of the two ions lay in the similarity of the radii of the two central atoms, in the equality of their co-ordination number and of the electric charges of the anions and also in the equality of the volumes of O'' and F'. At the end of the paper I stressed the fact that this investigation was still in progress. The direction in which the investigation was being continued is revealed in a petition which I addressed on April 29, 1929, to the *Notgemeinschaft der deutschen Wissenschaft* which contains this statement: "monofluorphosphoric acid H_2PO_3F resembles sulphuric acid H_2SO_4 so closely that it even gives alums, which are isomorphous with ordinary sulphate alums". Since the discovery of alums was to be foreseen by anyone after the publication of these facts, I delayed immediate publication of the new results, since they did not involve any new point of view.

I was, therefore, surprised to see in NATURE of Aug. 30, p. 310, a paper by Sir P. C. Ray on monofluorphosphates in spite of my notice that my work was being continued. Amongst other matters he prepared the alums which were to be foreseen. He also described as quite new facts his results, which he obtained with the aid of the conclusions which I had already indicated, without any mention of my name or acknowledgment of my work. Moreover, he did not give the method by which he prepared the PO_3F'' ions. I can only suppose then that Sir P. C. Rây is unaware of my work, although it appeared in one of the most widely circulated journals, and was indeed abstracted in *British Chemical Abstracts*, vol. A, p. 663, and in the *Chem. Zentralblatt* I. p. 2626, and in *American Chemical Abstracts*, vol. 23, p. 4903.

Raman Lines of Simple Polyatomic Molecules.

IN the course of a study of the structure of simple polyatomic molecules, the Raman spectrum of hydrazine, N_2H_4, was obtained with the view of finding the Raman line or lines which correspond to the symmetrical vibration N-N in polyatomic molecules. We should expect to find a line in the neighbourhood of 1600 cm.$^{-1}$, but the hydrazine spectrum showed three lines of roughly equal intensity at 3196 cm.$^{-1}$, 3270 cm.$^{-1}$, and 3344 cm.$^{-1}$, along with a very doubtful line at 1720 cm.$^{-1}$. These three lines are obviously due to N-H vibrations, and it seems curious that the symmetrical vibration should be so weak (if present at all) in the spectrum of this molecule.

Hydrazine hydrate, $N_2H_4H_2O$, gave the same three lines but with very much weaker intensity for comparable times of exposure. Both gave much continuous background, especially the latter. It appears from the results of other workers on polyatomic molecules that the vibration frequencies which turn up with greatest intensity in the Raman effect are those which correspond to symmetrical (inactive)

vibrations of the molecule. It had been hoped that a comparison between the hydrazine and the hydrazine hydrate spectra would show a difference in the intensity of the line corresponding to the N-N vibration in each molecule, but the results are so far indecisive on this point.

It is of interest to compare the three lines of hydrazine with the three lines which Daure (*Trans. Faraday Soc.*, Dec. 1929) gets in liquid ammonia, namely, 3210 cm.$^{-1}$, 3300 cm.$^{-1}$, and 3380 cm.$^{-1}$. Ammonia gas shows only one line at 3330 cm.$^{-1}$, according to Wood (*Phil. Mag.*, 7, 1929) and other workers; and it has been suggested that the triplet in the liquid is the result of association into molecules of the type H_3N-NH_3. On the surface, the hydrazine result would seem to strengthen this view, but one cannot be certain until the structure of hydrazine has been more fully worked out from its infra-red, as well as from its Raman spectrum. The work for this molecule is now being carried out here along with similar work for other simple molecules and upon the results it is hoped that a description of the exact selection rules will be obtained.

The Activity of Surfaces.

IN recent years a good deal of attention has been given to the relation between the catalytic effect of a surface and its structure, and in this connexion it is perhaps of interest to point out that the general idea underlying many theories was published by me in 1911 (*J. Chem. Soc.*, 475 ff., 1911) in a qualitative form. The hypothesis in relation to the specific problem studied, the dehydration of a salt crystal, was based on the view that the lattice structure of such a system was disturbed, and that the rearrangement of the surface (described as 'amorphous', in harmony with the prevailing views before the application of the X-rays to crystal analysis had been discovered) underwent a recrystallisation, a process which required time. It was further pointed out that "a treatment of somewhat simpler systems than the present, such as occur, for example, in the 'ageing' of deposited catalytic surfaces, would probably present points of interest"; and such has, in fact, proved to be so. This view of a catalytic surface is incompatible with a smooth 'chess-board' surface. The latter has now been recognised as inadequate. The application of the idea to heterogeneous reactions has been considered by Slonim (*Z. Elektrochem.*, p. 439, 1930). The examination of all such surfaces by X-ray analysis would, clearly, throw much light on the general problem, as Slonim shows in a particular case. The method contemplated had, however, the use of reaction velocity in mind.

Evolution and Ethics.

THE correspondence in NATURE of Nov. 29 under the heading "Heredity and Predestination" raises a topic of surpassing interest.

An ethical system of some kind is an essential adjunct of every social organisation. Apart from the social organisation to which it is related, any ethical system is a mere abstraction. On the other hand, a species without social organisation can have no ethical system. For such a species ethical values do not exist.

Ethical systems are in general just as much a product of evolution as are the bodies of individual organisms. If it were possible to view our own ancestry sufficiently far back, we should be able to trace an unbroken series commencing with a creature without social organisation or the possibility of ethical standards of conduct and proceeding by gradual steps to the present stage of organisation with its related standards, which, in conformity with the well-known dictum of Heraclitus, is no more permanent than its precursors.

Viewing the world of the present day, it is obvious that a variety of differing ethical systems are in actual operation in the human as well as in other social species. It is also obvious that the number of ethical systems which are theoretically possible is unlimited. The only condition that must be satisfied is that the ethical system must be in harmony with the society to which it applies. Failing such harmony, instability would ensue, with results which need not now be pursued.

Within the sphere of any ethical system the term 'good' applied to conduct means simply that the conduct is in accordance with the dictates of the system. The same conduct under another ethical system would possess a certain value, but would not necessarily be 'good'. Considered apart from all ethical systems no conduct can be assigned any ethical value.

So far as the comparison of ethical systems is concerned, it is impossible to condemn one or to favour another on ethical grounds. This is a field in which an ethical court can have no jurisdiction, as there are no ethical principles on which it can proceed. If one were to assume the superiority of one ethical system, it would be easy to condemn all others, but such a procedure would be transparently naïve.

On the other hand, there exists a court which does exercise jurisdiction in this field. As there is no appeal against its decisions, it is perhaps deserving of rather more consideration than it receives. The authority of this court depends on the fact that ethical systems have a most potent selective influence over the individuals composing the society in which the systems function. The existence of the social organisation shields the individuals comprised within it from many of the hazards that arise from the external environment. The selective effects of the external environment are thus minimised and their place is taken by the internal selective activity of the society itself, exercised in accordance with its ethical system. The more highly developed the social organisation the more far-reaching will this activity become. Ultimately the evolutionary trend—whether upwards or downwards—of the individuals composing the society will be controlled principally through this type of social selection. One ethical system will lead to degeneration and ultimately extinction, while another will lead in the opposite direction. We have here the *natural* criterion for discriminating between ethical systems. We are thereby enabled to apply the term 'good' or 'bad' to any ethical system, but it should not be overlooked that in such application neither term possesses an ethical connotation.

I will conclude by quoting in translation one of the less familiar fragments of Heraclitus:

"The Ephesians would do well to hang themselves, every grown man of them, and leave the city to beardless youths; for they have cast out Hermodorus, the best man among them, saying: 'We will have none who is best among us; if there be any such, let him be so elsewhere and among others'."

HUGH BIRRELL.

Huntington,
Ascot, Berks.

Determinism.

THE wide circulation and attractive style of Sir James Jeans's book, "The Mysterious Universe", will probably mark a step in the crystallisation of ideas towards the rejection of any mechanical system. But many will ask, Why go so far, and go no farther? Why have we dethroned a mechanical system and set pure mathematics to reign in its stead? The essence of a mechanical system, or to give it its more general name, Determinism, requires a single time sequence, proceeding in one direction, and postulates that each state is an inference from any past state, the necessary major premiss being Causation. One immense consequence of Einstein's ideas has scarcely yet been touched,—as the quantum theory undermined Causation, so relativity undermines Determinism and every other ethical theory by abolishing the time sequence.

Pure mathematics differs from this in possessing no time sequence; all its statements are interconnected so that each implies the others, and no statement is made at all other than the original axioms out of which it was evolved. Therefore it assumes the possession of complete knowledge of the theme before it makes any statement at all. If this leads to mysteries in the description of the universe, as well it may, it is hard to see why it too should not be rejected as unsuitable for the purpose, in the same way as we have rejected the animism and anthropomorphism of our ancestors. Pure mathematics is the last thing we would reject—if it goes, number goes, for the logic of pure mathematics depends upon number; and if number and the separation of objects of thought is discarded, all experience merges into one changing whole, incapable of exact description and communication to others. Apparently physical science owes its success to having elected to describe Nature on the lower plane of abstraction, where exact communication is possible. This is the alternative we may have to embrace. We can say with Faust, *Im Anfang war die Tat*, and nothing more. R. A. S.

Edinburgh.

Embryology and Evolution.

I HAVE read with much interest Prof. MacBride's review entitled "The Problem of Epigenesis", and I should like to make a few remarks upon what he says at the end. First of all, I wonder if the following analogy will help him, as it has helped me, to reconcile the conceptions of the geneticist with those of the embryologist. In a modern motor works the cars, so I understand, move along a track past a series of workmen, each of whom has one particular job to do, which is related to what has already been done and also to what is going to be done afterwards. Now if we imagine that all the parts and materials which are going to make up the finished car represent the substances in the developing embryo and that the workmen are the genes, we have an analogy which can be carried surprisingly far. Not only will it give us a picture of normal development, but we can see, by altering one of the parts, how a variation may occur; by altering a workman, how 'sports' may arise; and, by adding a new workman with a new job, how progressive evolution may take place.

There is no need for me to occupy space in working the analogy out, for anyone can do it for himself: what is more important is to point out where the analogy fails. A motor-car is adapted for life on the road, and, until it is completed, it has, for all practical purposes, no environment at all comparable with that which bears upon an embryo throughout its development. So whereas a feature of a car is simply due to the action of the workman on the materials, a feature of an animal is the result of the combined action of the genes and of the environment upon the materials of the embryo. Genes without the appropriate materials can produce nothing; genes with the appropriate materials can only produce a partially developed structure; but genes with the appropriate materials and environment can produce the fully developed functional character. Hence it is that in the development of the frog, for example, the gill-clefts, etc., are full developed, whereas in the Amniota, with the radical change in the environment of the early stages, such structures are only partially developed and the stages, to quote Prof. MacBride, are smudged.

Looked at from this point of view, two other conclusions of great importance are unavoidable. The first is that the recapitulation of an ancestral stage of the evolution of an animal, as distinct from the repetition of an ancestral character, will only occur when the early stage of development is passed in the same environment as that of the ancestor, which environment is different from that of the present-day adult. Only under such conditions will the genes responsible for the adult ancestral characters give rise to them all together without any great admixture of other features; though it must always be borne in mind that such stages in the life history, being larvæ, may evolve on their own account and, therefore, may have features which the ancestor never had. In parenthesis, I should just like to add here that, so far as I know, a larva has never been properly defined: such a definition would be "A free-living stage in an animal's life history which fends for itself and possesses certain characters which it has to lose before it can become a young adult": the possession of *positive* characters distinguishes a larva, not its lack of adult ones.

The other conclusion is reached thus. The appearance of a functional feature is dependent, as we have seen, upon the interaction of three things: the materials of the embryo, the genes, and the environment. Now the facts of Mendelian inheritance give clear evidence that there need be no change in the materials of an embryo for a new gene to modify the form, so, in discussing the origin of a new feature, there is no need to consider a change in the materials as one of the essential factors. The tortuitous appearance of a gene without the appropriate environment would produce a partially developed character, but, in actual experience, we do not find features in a partially developed condition which *have never been functional* at any period in the history of the race. So the genes must, in actual fact, only arise after the suitable environment is present; and the only conclusion to be drawn from that is that there is a causal relation between the two; that is, that the environment is in some way responsible for the appearance of the gene, which is surely nothing more or less than the basis of a new proof of the inheritance of acquired characters. G. L. PURSER.

The University, Aberdeen,
Oct. 29.

I HAVE read with interest Mr. Purser's thoughtful letter on the subject of my review. If he will substitute the term 'race-memory' for 'gene', we shall not be far apart. But the gene of the Mendelian stands out as something that is never functional. "No one", said the late Sir Archdall Reid, "ever heard of a useful gene." When one takes into consideration the fact that the Mendelian genes in *Drosophila* have been shown to increase in their damaging effect on the viability of the organism in proportion to the structural change which they involve, and when further it is discovered that genes can be artificially produced by irradiating insect eggs with X-rays—a

process which kills most of the eggs—one is driven to the conclusion that a gene is germ damage of which the outward manifestation is a mutation. The only effect that natural selection would have on such aberrations would be to wipe them out. In my opinion, mutations and adaptations have nothing to do with one another and only adaptations are recapitulated in ontogeny. E. W. MACBRIDE.

Administration and Anthropology in India.

THE leading article in NATURE of Nov. 22 appears at a critical moment and must be deeply appreciated by everyone who knows anything of the present state of affairs in India, political or academic. It rightly stresses the literary bias of research in India, in answer to which it may be pointed out that, whereas the older universities teach Indian languages, the University of London is the only English university to accept Indian cultural studies for the B.A. degree (Hons. Archaeology, Sect. H). It is true that field-work is non existent in India, and that, therefore, the bulk of the anthropological research carried out must be more or less arid, because it is at second-hand and divorced from the facts. As an outcome of this, we are now faced by the peculiar prospect of listening to a lengthy debate, and of accepting willy-nilly a decision of sorts, upon a subject that is nothing else than a problem in applied anthropology, that is, the organisation of a federal India; and we are forced to do so with the knowledge that the facts are not accessible. Whatever is done must, therefore, be done in the dark. The action taken will be political and not scientific. One would have liked to have heard Huxley's views on such a state of affairs!

The problem has, however, been foreseen by many people, most of them harassed government officials, who, following the magnificent Anglo-Indian tradition of Tod, Sleeman, Cunningham, and Meadows-Taylor, have found time to make themselves acquainted with scientific thought, but were never free to undertake research. In spite of Risley and Thurston, and the solitary excellence of Sarat Chandra Roy, it is not possible, in the present state of our knowledge of India, even to begin to discuss the basic problems of Indian ethnology. The district gazetteers are a mine of information, but they are uncorrelated compilations. The very terminology is lacking, because no body of scientific opinion has ever been brought to bear on Indian studies. If the delegates of the Round Table Conference were to be suddenly and blessedly converted to science, it is doubtful whether six people could be brought before them who could speak with authority upon India as a whole. It is not enough to explain the dearth of Indian scholars by saying that India is a continent in itself and a whole compound of races, beyond the ability of one man's compass. So are China and Africa, both of which are academically well represented. The only answer is that India has been academically neglected. The remedy is in the hands of the teaching bodies.

Incidentally, should not a candidate for the Indian Civil Service know a very great deal about the history and culture of the peoples to whose welfare he is devoting his life? It may be asked, Where *does* the Indian administrator get his knowledge from? The answer is that he picks it up. He certainly does not get what he needs from the older universities.

Foaming of Beer.

I DO not know sufficient of chemistry to appreciate the full inwardness of Sir Robert Robertson's commentary on my letter in NATURE of Sept. 20, but I am convinced that the phenomena in question are not purely chemical, and that a physical, and even a directly mechanical explanation, is at least partly appropriate. I have in mind the air lift pump.

As a matter of interest I tried pouring a gassy beer into a champagne glass and it was quite flat. But more convincing was a letter from a well-known professor at Harvard, who states that the mid-west 'hobo' sought to combat short measure by greasing the inside of his tin can or pail with ordinary soap. These 'hobos' argued that they got enough fresh air without drinking it. The Harvard professor, whose initials coincide with my first two, experimented on foaming phenomena and found that something like 20 per cent could be gained by soaping. He was told that the quality of the beer was such that the taste was not unpleasantly affected.

It is permissible to observe that the 'hobo' did not use a glass vessel, and to judge by his name, he would not allow sufficient time for soap to be absorbed or dissolved by the beer. Moreover, my Harvard correspondent does not explain why a slippery container kills froth. H. S. ROWELL.

Ball Lightning.

IN view of the interesting letter from Dr. A. Russell on the above subject in NATURE of Nov. 22, and his remarks as to the undesirability of touching these mysterious globes, the following case (quoted from Flammarion by Prof. Ignazio Galli in *Mem. Pont. Acc. Rom. N. Lincei*, **30**, 281-2; 1912), when the experiment was actually tried, might be of interest.

During a storm at Beugnon (Département Deux-Sèvres, France) about the year 1904, a globe approached the door of a cattle-shed where were sheltering two children. "One of the children had the courage to touch it with his foot; immediately a frightful detonation shook the walls of the farm, the two children were thrown to the ground, without any wound, but eleven head of cattle were killed in the stable."

Prof. Galli also quotes (*ibid.*, 272) many cases of globes accompanied by a sound variously described as blowing, whistling, roaring, buzzing, and crackling.

CICELY M. BOTLEY.

Hastings, Nov. 24.

A Toy Balloon's Long Flight.

SOME fourth form boys here have recently been carrying out several simple researches. One such research, on air currents, included the liberation of coal-gas-filled balloons. One flight is sufficiently remarkable to be worth recording.

A Woolworth threepenny balloon was liberated near Johnstone, 12 miles south of Glasgow, 100 feet above sea-level, on Oct. 26, at 12.30 P.M. It reached Stony Stratford, in Buckinghamshire, after a journey of at least 310 miles, and was picked up next day at 10.30 A.M.

Alan Hird, the experimenter, remarks: "The day was fine and sunny, in fact it was the only officially 'dry' October day in this part of Renfrewshire, and a strong, steady N.W. wind was blowing."

The De-Nationalisation of Helium.

By HENRY B. MILNER.

THE disaster to the British airship *R101*, still fresh in the public mind, torn between sad memory and impatience to learn the findings of experts now holding a court of inquiry, has had, as it was bound to do, world-wide repercussion. Everywhere dirigible construction, either in project or in progress, has received an abrupt check. Whatever may be the ultimate technical findings of this court, it is safe to assume consensus of opinion on at least one point: the danger of hydrogen, the urgency of helium. In Germany the Zeppelin Company was engaged in laying down a new airship to be known as *LZ128*, but the lesson was quickly learnt. Complete revision of plans of construction was undertaken, in which the salient factors were provision for the exclusive use of helium and heavy, virtually non-inflammable, oil-fuel, in place of hydrogen and the 'Blau' gas fuel hitherto employed in Zeppelins. Clearly, even at the expense of a year's delay, Dr. Eckener is in no mind to chance a re-enactment of the deplorable tragedy which we have just witnessed.

At the same time, such plans might well be frustrated and progress reduced to complete standstill if resources of helium were not forthcoming. Since the United States holds a virtual monopoly of this valuable gas, then clearly the question of future supplies is the crux of the situation for everyone concerned. Dr. Eckener announced to the American Chamber of Commerce in Berlin last month (*Times*, Nov. 6) that the embargo on helium export from the United States had just been removed, which made practicable the execution of the revised plans for *LZ128*. It is interesting to review the situation and the chain of events which have made possible this release.

The original law relating to the export of helium from the United States is contained in Section 4 of the Act approved March 3, 1927 Public, No. 758, 69th Congress which states: "That hereafter no helium gas shall be exported from the United States . . . until after application for such exportation has been made to the Secretary of Commerce and permission for said exportation has been obtained from the President of the United States, on the joint recommendation of the Secretary of War, the Secretary of the Navy, and the Secretary of Commerce. . . ." The Act also authorises "the conservation, production, and exploitation of helium gas, a mineral resource pertaining to the national defence . . .", and places the jurisdiction of Government plant under the Bureau of Mines, from which Bureau the Army, Navy, and other branches of the Federal service will requisition it as required.

Specific mention of the Government plant recalls the existence of the U.S. Helium Production Plant near Fort Worth, Texas, the helium being actually extracted from natural gas of the Petrolia-field, Clay County, Texas. Until 1928, practically all the helium produced came from this source, but it was then found that this source of supply was inadequate to international demands. The effect of the Act was to stimulate investigations by the Bureau of Mines into supplementary resources, and in April of that year a contract was made between the Government with the Amarillo Oil Company of Amarillo, Texas, to exploit the gas from leases on what is known as the Cliffside Structure in that region. While it was a vital matter to develop such helium-bearing gas resources as could be found, questions of the prospective life of such supply, also facilities for disposing of the 'treated' gas, had to be faced. The estimates proved satisfactory so far as the first point is concerned, and the Company having agreed to take care of the treated gas, developments went ahead, so that in August of that year the new plant-site was selected at Soney, some six miles from Amarillo, and almost coincidently the Company brought in a new gas well having an open flow volume of more than seven million cubic feet per day, with a helium content of about $1\frac{3}{4}$ per cent by volume, the average for gas produced from this particular structure.

By May of last year the first tank-car filled with about 200,000 cubic feet of helium was dispatched from Soney to a place in Virginia. This helium was transported under a pressure of 2000 pounds per square inch and ultimately discharged into stationary containers for use in connexion with the U.S. Army dirigibles. Thereafter the new plant continued more than ever to justify initial confidence, both in itself and in the quality of the gas handled. In September 1929 there was produced from Amarillo 874,840 cubic feet of helium with the remarkable factor of 97·7 per cent purity, at an operating cost of 17·63 dollars per thousand cubic feet of contained helium, a much reduced cost compared with that previously involved. In January 1930 the output of helium was more than a million cubic feet of gas with a purity factor of 97·85 per cent, at a still further reduced cost of 9·64 dollars per thousand cubic feet.

The significance of this purity factor will be more readily understood when it is realised that a Navy dirigible (U.S.) of $6\frac{1}{2}$ million cubic feet capacity has about 5 tons more lift when filled with helium of 98 per cent purity than when the purity factor is only just over 95 per cent, the average of the Fort Worth product.

A Department of Commerce 'Press release', dated Aug. 20, 1930, shows that the helium output for the fiscal year ending June 30, 1930, attained the high figure of 9,801,060 cubic feet, the largest ever achieved, and it is pointed out that the plant was only operated at a fraction of its real capacity, the latter determined almost entirely by the U.S. Army and Navy demand. This communication also contains the statement, "Under present conditions it costs less to operate Government airships with non-inflammable helium than it would cost to operate them with flammable hydrogen". At this point we leave this amazing record of progress

until *R101* showed the vital need of de-nationalisation of helium.

With such resources at her command, with her service and commercial needs amply provided for, an international call for exported helium could not remain for long unheeded, in the interests both of humanity and the future of the airship. On Oct. 11, 1930, the Department of Commerce, apparently satiated with inquiries relative to the helium export situation, cleared the air by publishing a memorandum setting forth the provisions to be observed when sanction for export was requested. These provisions are entirely reasonable, including among others, the quantity to be exported, the purpose for which the helium was destined, and the country to which it was being sent. It is therefore obvious that Section 4 of the Act is to all intents and purposes inoperative, and that this invaluable commodity is henceforward available to all *bona fide* demands.

The Testing of Wood Preservatives.

THE problem of carrying out tests in the laboratory to give a rapid indication of the probable effectiveness of any material as a wood preservative is one which has arisen on many occasions in different countries and a number of different methods have been evolved. Unfortunately the results obtained have frequently been in no way comparable and efforts are being made to standardise the different methods. Following a conference of American workers, early this year at St. Louis, on the standardisation of laboratory methods for the measurement of the toxicity of wood-preserving materials, the wish was expressed that the European investigators should gather together at a similar congress to discuss the conclusions which had been reached at the American meeting, and to describe the methods up till now used in Europe, which differ considerably from those used in America.

The conference, which was convened on the initiative of Dr. Hermann von Schrenk of St. Louis, met in June at the Biologische Reichsanstalt, at Berlin-Dahlem, and included representatives from Austria, Denmark, Germany, Great Britain, Holland, Japan, Norway, Switzerland, and the United States of America. The Department of Scientific and Industrial Research was represented by Mr. W. P. K. Findlay, of the Forest Products Research Laboratory, Princes Risborough. The matter for discussion was put forward under the following three heads:

1. Which method of investigating wood preserving materials appears, in the light of experience so far obtained, to be the most certain and the most reliable?

2. Which wood-destroying fungi should be used for carrying out these experiments?

3. What conclusions as to the value of a wood preservative in actual practice may be drawn from a determination of its toxicity?

1. METHODS.

It was stated, according to the conclusions of the American conference referred to above, that in the United States the fungicidal power of wood preservatives under test is determined only by the method of using petri dish cultures of certain fungi upon agar medium containing the preservative The reason for accepting this method is the exactitude with which the amounts of preservative and the point of inhibition may be determined. Experiments have, indeed, been made in the United States using the wood block method customary in Europe, but the results obtained there by this method have not proved satisfactory, because the use of different species of wood, or of woods of the same species of different resin contents or containing different proportions of spring and summer wood, or, finally, of woods with a varying capacity for impregnation, has introduced so many variables into the method that strictly comparable results could scarcely be expected. The use of sawdust, or of discs made of wood meal, has certainly lessened these difficulties, but, nevertheless, the agar method is considered as far exceeding all others in accuracy and as particularly convenient, because results can be obtained from it in a shorter time than from any other method.

In opposition to the American point of view, all the European research institutes were of the opinion that the wood block method should have first place in importance, the following arguments being advanced in support of this view:

All laboratory experiments on the preservation of materials should in general be carried out on the material in question, using as the attacking agent the appropriate micro-organism concerned. Experience has shown that a preservative may easily inhibit the growth of a micro-organism in agar or gelatine for example, while this same organism will develop quite unchecked by the preservative used in another substratum. The difference in behaviour may be due to such causes as chemical reactions, absorption phenomena, changes in the coefficient of dispersion, and so on, which cannot always be foreseen. Such phenomena have been observed in the case of wood-preserving materials and a number of instances were quoted during the discussions. It was shown by means of tables and figures how some wood preservatives may have the same effect in wood as in agar, while others produce a many times greater effect in agar than in wood. Values obtained in agar cannot, therefore, be taken as applying for wood without further investigation; it was considered that an opinion as to the preservative properties of an antiseptic can only be established by experiments carried out with all necessary precautions upon wood blocks.

Against the objection of the American workers, put forward by Dr. von Schrenk, that the use of wood blocks introduces too great a variability into the experiments, which is absent in the agar method, it was shown that while the undeniable variability of wood may introduce differences amounting to

approximately 10 to 20 per cent, these differences are without significance in comparison with differences of 1000 per cent or more which might easily appear when conclusions are drawn as to the toxicity of a material in wood from figures derived from agar tests. The agar method may in this way lead to false conclusions.

In addition to the agar and wood block methods which had been discussed, mention was also made of methods involving the use of cooked rice or of sawdust as nutritive substrata. At Zurich a modification of the latter method is customary, in which the wood-destroying fungi are cultivated on sawdust prepared from impregnated wood, and as a measure of the amount of the fungus attack, the xylan and the cellulose contents are determined before and after the growth of the fungus.

2. CHOICE OF FUNGI.

As the first standard fungus, *Fomes annosus* was chosen in America because this fungus is considered to be specially resistant and easy to grow. In addition, other species of fungi (species of *Lenzites*, *Polyporus*, *Polystictus*, *Coniophora*, etc.) have occasionally been used for comparative experiments.

Against the use of *Fomes annosus* general objection was raised because this fungus does not, in practice, come into consideration as a destroyer of dead, constructional timber and it cannot, therefore, be regarded as a typical wood destroyer. Neither can *Fomes annosus* be regarded in general as particularly resistant, since, while it may be very resistant against certain antiseptics, in respect of others it is surpassed by other fungi. On account of the varying behaviour of different fungi to the same antiseptic, it is not sufficient to carry out the experiments with only one fungus; it is much better that several species should always be used. Not only do the values determined for the inhibition point of any particular material in agar fail to agree with the values obtained in wood blocks, but the relation between the agar value and the wood block value may be different for one and the same material for different fungi. It is, therefore, not possible to determine the inhibition points for numerous fungi by the agar method and for a single fungus by the wood block method in order to calculate, from the relation determined for this one fungus, the inhibition points in wood for the other fungi. Several fungi should, therefore, be used in each wood block test against any one preservative. The fungi should be chosen after consideration of the use to which the timber treated with the particular preservative will eventually be put (whether in sleepers, poles, or as building timber). Obviously the choice will also depend upon the species of wood used (frondose or coniferous).

Further, it was shown that not only do species of fungi differ in their resistance and virulence, but that the strains of one species may also show differences amongst themselves, in consequence of which it will be necessary for the different research institutes to make use of the same strains of fungi of known origin, if the values are to be internationally comparable. The Biologische Reichsanstalt at Berlin-Dahlem expressed its willingness to supply strains of fungi having the same origin, if the research institutes could come to an agreement as to the species and strains or races to be used.

Until now the effectiveness of preservatives has been tested only against infection by mycelium; tests against spore infection are equally important and deserve further consideration.

3. INFERENCES FROM TOXICITY DETERMINATIONS.

It was agreed that the inhibition figures determined by the wood block method are only of value for practical application if the laboratory experiments are supplemented by field experiments and by investigations to determine the liability to leaching and to evaporation, and the physical and chemical stability in wood, and so on. But from a consideration of all these points valuable conclusions may be drawn as to the probable preservative power of a material in practice, especially when it is possible to compare the new material under test with other known materials of the same type.

CONCLUSIONS.

The conclusions reached were as follows:

1. The wood block method (using the Kolle flasks), which was thoroughly discussed by the conference, should be considered as a suitable means for estimating the effectiveness of a wood preservative against fungi. The agar method should only be considered as of value for the preliminary investigation of the toxicity to fungi of any new material.

The inhibition point in the wood block method shall be expressed as kilograms of preservative per cubic metre of wood. In the agar method the inhibition point shall be expressed as the interval between that concentration of the material under test, in the artificial medium, at which growth just takes place and the next concentration above it in the series, which prevents all growth.

2. It should not be considered sufficient to carry out the tests under consideration with one fungus only. Much rather should it be the aim to carry out all tests on impregnated wood with two fungi; the exact species still to be decided upon, but one of them should be *Coniophora cerebella*.

3. The conference was unanimous that the determination of the toxicity to fungi of any material is not alone sufficient to determine its value as a wood preservative, and that investigations as to its susceptibility to leaching, and on its physical and chemical stability in the wood, must also be taken into consideration.

In view of the wide field for discussion, the conference resolved not to regard the two days' discussion as in any way final, but rather to look upon itself as a sort of permanent working committee of people interested in the subject. In order to make the work easier, the following committee was set up: Prof. Liese, of the Forestry School, Eberswalde; Prof. Nowak, of the Wood Industry Technical and Chemical Research Institute, Vienna; Dr. F. Peters, of the Rütgers Company, Berlin; and Dr. A. Rabanus, of the I.G. Farbenindustrie A.G., Uerdingen.

Crust-movements connected with Tango (Japan) Earthquake of 1927.

IN no other earthquake have the movements of the crust been studied so exhaustively as in the Tango earthquake of Mar. 7, 1927. In several districts, such as those of the Californian earthquake of 1906 or the Kwanto earthquake of 1923, the series of levellings have been repeated once, but after the Tango earthquake they have been repeated again and again, with a lavish expenditure of trouble for which seismologists are deeply indebted to the Land Survey Department of the Imperial Japanese Army. Series of precise levellings were carried out during April-June, June-July 1927, Mar.-April 1928, and Aug.-Oct. 1929, while the re-triangulation of the central district was made during May-June, Aug.-Sept., and Oct.-Nov. 1927, and April-Sept. 1928. The results of the repeated measurements have been studied by Prof. C. Tsuboi, of the Earthquake Research Institute, in an admirable series of papers published in the *Bulletin* of the Institute (vol. 6, pp. 71-83: 1929; and vol. 8, pp. 153-220, 338-345; 1930).

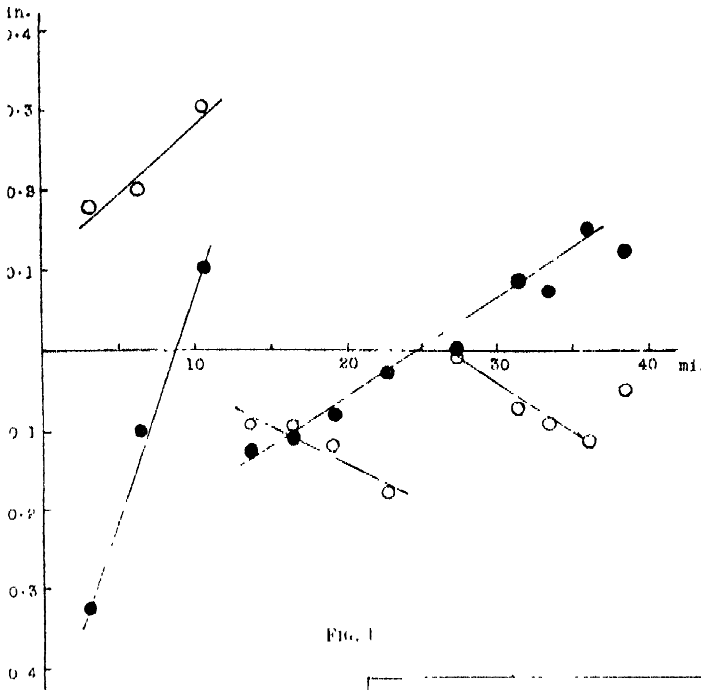

FIG. 1

The first of these memoirs is confined to the vertical displacements that occurred during the intervals between the first and second and the second and third series of levellings. Diagrams are drawn representing these displacements along nearly straight portions of the levelling route. One of them is reproduced in Fig. 1, in which the small black dots indicate the displacements during the first interval and the small circles those during the second. It is clear from this and similar diagrams (i) that the points lie nearly on segments of straight lines, and (ii) that the ends of these segments lie on the same ordinates for both series of graphs. These features are well explained on the supposition that the crust is made up of a number of blocks, each of which behaves as a nearly rigid body and, at any rate after the earthquake, was able to move with comparative ease apart from its neighbours. The boundaries of the various blocks have been drawn, and it is remarkable how closely they agree with the known fault-lines of the district. Two other points of some interest are also evident from Fig. 1 and other diagrams, namely, (iii) the tilting of the blocks in some cases takes place in opposite directions in the two intervals considered, while

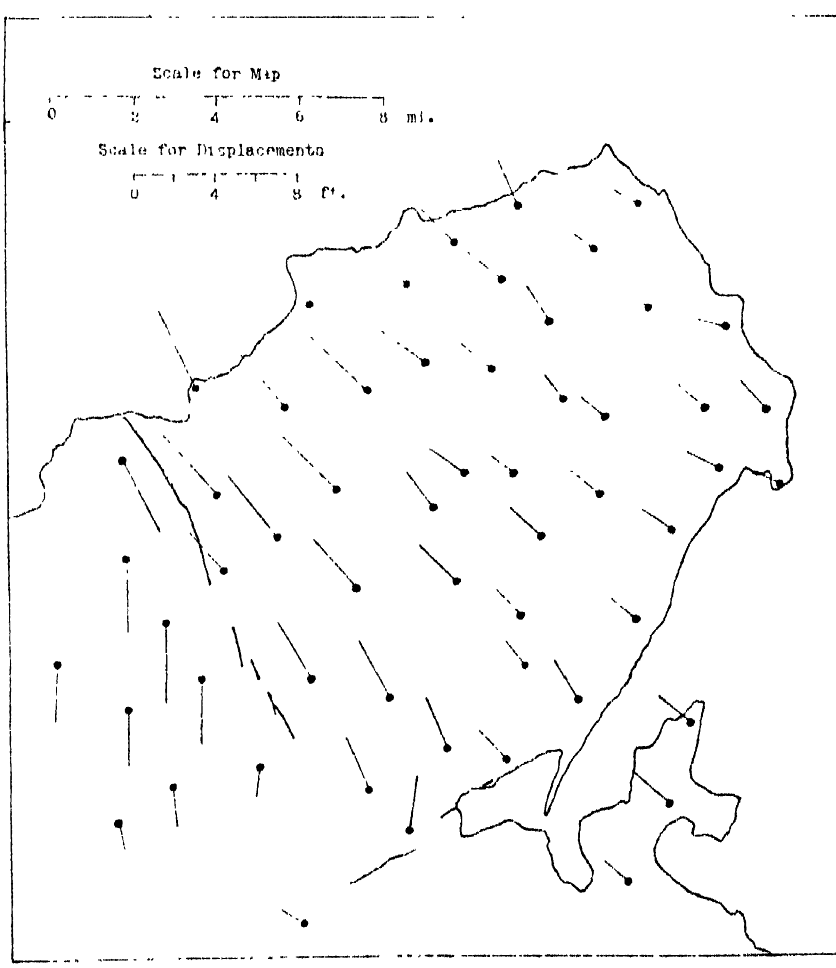

FIG. 2

(iv) Fig. 1 shows that two blocks were subjected to a common tilting during the earlier stage but moved separately during the later.

At the time of the earthquake, two remarkable faults were renewed along old lines of dislocation. They are represented by the thick lines in Fig. 2. The Gomura fault, or series of faults, is 11 miles long, and runs in the direction S. 30° E. along the western boundary of the Oku-Tango peninsula. Relatively to the other side, the crust to the west of the fault was shifted as much as 8 ft. 2 in. to the south and uplifted about 1 ft. 8 in. The Yamada fault is about 4½ miles long, and runs in the direction N. 55° E. along the southern boundary of the peninsula. The crust on the north side of the fault was raised by as much as 2 ft. 3½ in. with respect to that on the other, and shifted 2 ft. 7½ in. to the east.

The main line of levels crosses both faults. The vertical displacements of the bench-marks between 1888 and the first series of levels after the earthquake show that the ground to the west of the Gomura fault has been generally tilted westwards, while the block bounded by the two faults has been tilted to the north by as much as 20″. Similar curves have been drawn for each of the three intervals between successive series of levellings, and it is worthy of notice that, while the curve for each interval differs materially from that up to the first series, the curve representing the total displacements between the first and fourth series resembles it very closely.

No less interesting are the results of the repeated triangulations of the district. Assuming that two points some distance to the south have remained stationary, the displacements of the various points after the fourth triangulation are represented in Fig. 2. From this, it is seen that the mass of the Oku-Tango peninsula has been displaced as a whole, with but slight deformation in itself, in a nearly north-west direction. Maps for the intermediate periods are also given, but they show no tendency to uniformity of displacement like that during the longer interval. One of the most striking features of the map is the discontinuity in the horizontal shifts along the Gomura fault. The greatest displacement measured (of 5 ft. 4½ in.) occurred at Asago, close to the Gomura fault. At two points, Simooka and Yosizawa, one on either side of the fault, displacements of 4 ft. 1 in. and 3 ft. 7 in. occurred in opposite directions nearly parallel to one another and to the fault. The sum of these amounts (7 ft. 8 in.) does not differ much from the total shift of 8 ft. 2 in. observed in a neighbouring portion of the fault.

C. DAVISON.

Obituary.

PROF. PAUL APPELL.

OF the three eminent mathematicians who dominated French science at the beginning of this century, Paul Appell, who died on Oct. 23, aged seventy-five years, will pass down to posterity as an analyst of genius, whose personal charm was equal to the excellence of his teaching. Together with Henri Poincaré, whose mathematical achievements have still to find their equal, and Emile Picard, whom destiny has now left alone to represent the glory of his generation, Paul Appell has laid the foundations upon which a succession of research students and mathematicians have built. Indeed, his masterly "Traité de Mécanique Rationnelle" (1893-1896) maintains its position as a standard text, side by side with the "Traité d'Analyse" of Picard, and the "Méthodes Nouvelles de la Mécanique Céleste" of Poincaré.

Many of our own text-books on pure and applied mathematics still use Appell's lucid demonstrations of difficult problems, such as, for example, the finding of the area of a closed surface, or of the area swept by a moving line, on which is based the theory of the planimeter. But Appell went further than that in his wonderful work: guided by a remarkable intuition, he developed in unusual directions some of the subtlest parts of mechanics, although no experiments of that time could be quoted in support of his views. So he prepared the way for Einstein, whose theories he confirmed later in a supplementary volume on mechanics which he wrote in collaboration with his former pupil, Prof. Thiry.

The fundamental ideas of Paul Appell on higher analysis, which are scattered in a large number of monographs and contributions to learned publications, can be found in his "Théorie des Fonctions Algébriques et de leurs Intégrales" (1895), written in collaboration with Prof. Goursat, and in his "Principes de la Théorie des Fonctions Elliptiques" (1897), written in collaboration with Dr. Lacour. Functions of an analytic point, series and definite integrals, periodic functions and functions of several variables, differential equations and their invariants, equations with partial derivatives, and the theory of potentials, are among the abstruse questions which he attacked successfully; and one should not forget his brilliant memoir on higher analysis, with which he secured the second prize in the international mathematical competition organised in 1889 by the King of Sweden, when Poincaré carried the honours of the day.

It is, however, with his thesis on pure geometry that Appell began his mathematical career in 1876, when he generalised the notion of involution discovered by Chasles, and made some remarkable applications of it in the theory of cubics. He was then awarded the degree of Doctor of Science and became lecturer in mathematics at the University of Dijon. In 1881 Appell was appointed to the chair of applied mathematics at the École Normale Supérieure in Paris, and in 1885 he was awarded the *Prix Bordin* for his memoir on the solution of a special problem first suggested by Monge.

In 1892 Appell was elected to the Paris Academy of Sciences, and in 1903 he became Dean of the Faculty of Science, and, soon after, a member of the Higher Education Council, in which capacity he exercised a far-reaching influence over the whole field of university education in France. In 1920 he

was appointed Rector of the University of Paris, whence he retired some years after on account of ill-health. On several occasions Paul Appell received the highest distinctions from French and foreign universities; and in 1924 Oxford conferred on him the honorary degree of Doctor of Science.

As a teacher, Paul Appell knew how to win the affection of his students by his patience, his kindness, his readiness to discuss difficulties, and his extraordinary ability in finding illuminating explanations for the most complicated questions he had to deal with. Those who were privileged to know him more intimately were not long in discovering his high moral virtues and also the secret sorrow of his heart. For Paul Appell was born in Strasbourg in 1855: and as a result of the Treaty of Frankfurt, sixteen years later, he was prompted to abandon his "petite patrie" for the sake of his "grande patrie, la France", to the restoration of which he was determined to devote his strength and energy. He tells his poignant story in his charming book, "Souvenirs d'un Alsacien", which makes his biographers' task an easy and pleasant one, and shows in all their simplicity and greatness his patriotic feelings. But more qualified pens will one day describe what his country and science owe to Paul Appell. These few inadequate notes are only meant as a respectful homage to the memory of a great man who was revered and admired by all who knew him. THOMAS GREENWOOD.

PROF. J. H. TEACHER.

By the premature death on Nov. 21, at the age of sixty-one years, of Prof. John Hammond Teacher, the School of Medicine of Glasgow has lost a valuable member of its personnel. Educated at the Glasgow Academy and the University of Glasgow, he graduated in arts in 1888 and in medicine with 'High Commendation' in 1893. He took the higher degree ten years later and was awarded honours and a gold medal for his thesis.

It is probably true to say that of his teachers Dr. Joseph Coats was the most influential in determining Dr. Teacher's bent. From the first his interests centred in the problems of pathology. After serving as house surgeon and for a time as medical officer of the Rio Tinto Company in Spain, where he had the opportunity of observing the life-history of the malaria organism, he returned to undertake an important duty for his University. The celebrated Anatomical and Pathological Collection of William Hunter had long stood in need of reconditioning and rearranging. Dr. Teacher was appointed to do this, and after some years of work, produced a valuable two-volume catalogue of the collection, with descriptions and annotations which testify to the care and insight with which he had carried through the work. The volumes are prefaced by an interesting and scholarly introduction on William Hunter and his school in relation to the collection.

Dr. Teacher next spent some years as assistant to the professor of physiology, being chiefly engaged in the histological work. Here he was able to perfect his microscopic technique, which was of a high order. About this time he entered upon a study of the remarkable disease known as chorionepithelioma, and to further this he travelled abroad to make acquaintance with all the early human embryos then known. Presented as a thesis, this memoir received recognition from his University, and was acknowledged an important contribution to the subject. In 1904 he joined the staff of Prof. Muir, and in view of his special proficiency and interest in microscopic work he was nominated by him for the lectureship in pathological histology. In 1909 he was appointed pathologist to Glasgow Royal Infirmary, and this appointment was followed in 1911 by his election to the St. Mungo (Notman) chair of pathology instituted in 1910. As St. Mungo professor he was *ex-officio* pathologist to the Royal Infirmary, and his professorship was inaugurated by the opening of the excellent new Pathological Institute, for the planning and organisation of which he was largely responsible.

Teacher's work on chorionepithelioma gave him a special interest in the history of the chorion in early development, and this was greatly enhanced by his discovery in 1907 of a very young embryo, the youngest hitherto known, in a minute piece of decidua sent to him for examination. The specimen was described in a memoir published in 1908 in conjunction with the writer of this notice. In 1923 he discovered another young embryo at an autopsy, and published in the *Journal of Obstetrics and Gynæcology* of the British Empire (1924) a very able and beautifully illustrated memoir on the history of the trophoblast and on the implantation of the blastocyst in the human subject. The contributions he made in these two memoirs to the problems connected with the earliest phases of human development have left his name permanently and honourably inscribed in the literature of the subject.

Apart from the reputation he won in this field, Teacher acquired merit for the able manner in which he conducted his routine duties as pathologist to the Royal Infirmary. To the literature of pathology he from time to time contributed papers (too many to be enumerated in this short notice), which were invariably characterised by accurate observation and careful presentation. His special interest, determined by the studies already referred to, was in gynæcological pathology, and he had accumulated a large amount of material for a book on the subject. It is a great misfortune that he was not granted time to carry this work to completion. T. H. B.

CAPT. OTTO SVERDRUP.

OTTO SVERDRUP'S name, like those of his fellow-countrymen, Nansen and Amundsen, ranks high in the story of polar exploration. In a long course of arctic voyages, he had become the most experienced ice-master of his time, and his knowledge was sought by many expeditions.

Sverdrup, who died in Norway on Nov. 26, was

born on Oct. 31, 1855, on a farm in Helgeland, Norway. He went to sea at the age of seventeen and sailed for many years in American and Norwegian ships, besides having experience in fishing boats. For some years he had left the sea, when in 1888 he was chosen by Nansen for his memorable expedition across the ice-sheet of Greenland. The party reached the west coast after their crossing, and then Sverdrup and Nansen made a daring journey in a crazy and scarcely seaworthy boat to Godthaab to bring help to the other men.

In 1893 Sverdrup was chosen by Nansen to command the *Fram* in her drift across the Arctic Ocean. When Nansen left the ship in lat. 84° N. with Johansen as a companion in an attempt to reach the north pole, Sverdrup took over command of the expedition, and eventually extricated the ship from the pack-ice and brought her safely to Norway after a three years' drift. The highest latitude reached by the *Fram* was lat. 85° 57′ N., which is still the northern record of any vessel.

In 1898 Sverdrup returned to the arctic with the *Fram* in an attempt to explore the north of Greenland. Ice in Robeson Channel barred the way, and Sverdrup transferred his attention to Ellesmere Island and the unknown regions lying to the west. During the first year, from a base at Cape Sabine he explored much of Ellesmere Island, and in the two years following he charted much new land to the west and threw light on the nature of that part of the arctic. The islands he discovered are known collectively as the Sverdrup Islands. The *Fram* returned safely to Europe in 1902.

Sverdrup's next important arctic voyage was in 1914, when he was charged by the government of Russia with the task of searching for the lost Russian explorers, Brussilov, who had sailed in *Ste. Anna* in 1912, and Russanov, who sailed the same year for the Kara Sea. Sverdrup in the *Eclipse* passed through the Kara Sea, reached the Yenisei mouth, and eventually wintered in lat. 76° N., long. 92° E. In August 1915 the ship was liberated from the ice and resumed the search, which, however, proved fruitless. This expedition made several discoveries, but most of the detailed records were sent to Russia and have never been published. In 1920 Sverdrup again took an expedition to the Kara Sea, to bring help to a Russian ice-breaker imprisoned in the pack. He gave valuable advice in the rescue of the survivors of the *Italia* airship in 1928.

Sverdrup was a silent man and his great store of knowledge was not easy to reach. His chief book was "New Land" (London, 1904), and he wrote nothing on many of his expeditions. He was an honorary LL.D. of the University of St. Andrews.

R. N. R. B.

MR. JAMES EDGE-PARTINGTON.

WE regret to record the death of Mr. James Edge-Partington, which took place at Beaconsfield on Nov. 4, at the age of seventy-six years. Mr. Edge-Partington was an authority on the material culture of the Pacific, and at one time was the owner of a very extensive collection of objects from the South Seas, which included many rarities. This was dispersed during his lifetime, part going by purchase and gift to the British Museum and part to the Auckland Museum. A second collection of books and prints relating to Australasia went to an Australian museum. Mr. Edge-Partington's contributions to scientific literature, which were numerous, were mostly descriptive, but they were characterised by extreme accuracy, critical acumen, and a common sense which was allied with a sound appreciation of the bearing of the analytical study of material culture on the problems of ethnology. His most important contribution to anthropological literature, however, was an ethnographic album of the Pacific in which tools, implements, personal ornaments, and other objects in European collections, especially his own and that of the British Museum, were reproduced by lithography from his own drawings. It was issued in three series, which appeared in 1890, 1895, and 1898 respectively. It is now extremely rare, very few copies remaining in private hands. Mr. Edge-Partington's interests were not confined to the Pacific; he was also a keen student and collector of objects illustrating the culture of the European peasantry, and had devoted much attention to the peasant industries of the Chiltern area in which he lived. For many years he was a valued voluntary worker in the ethnographical department of the British Museum, and a very active member of the council of the Royal Anthropological Institute.

PROF. WALTER HERZ.

DR. WALTER HERZ, professor of physical chemistry in the University of Breslau, died on Sept. 7, aged fifty-five years. From the *Chemiker-Zeitung* we learn the following particulars of his life. Herz was a native of Breslau and at the University of that city he studied under Ladenburg, who quickly recognised his ability both as an original worker and as a teacher. Under Ladenburg's direction, it was only natural that Herz should direct his attention first to organic chemistry, but after graduation his interests in other branches of the subject were awakened by F. W. Küster and R. Abegg. Under their influence he began to devote himself to investigations in physical chemistry, particularly to problems of solubility, chemical equilibria, partition coefficients, viscosity, and critical states. In 1903 Ladenburg appointed him first assistant in the Chemical Institute at the University of Breslau. In 1909 he was transferred to the Pharmaceutical Institute, but in 1919 he returned to the University as director of the department of physical chemistry in the Chemical Institute. Herz was the author of numerous volumes, the best known of which is his "Leitfaden der theoretischen Chemie". In conjunction with Abegg he compiled a "Chemisches Praktikum" and with Gadamer a work on chemical toxicology. He succeeded Ahrens in editing the *Sammlung chemischer und chemisch-technischer Vorträge.*

News and Views.

AT the anniversary meeting of the Royal Society, Sir Ernest Rutherford, the retiring president, announced that by an alteration of the existing statute regulating the election of fifteen fellows annually, and enacted in 1847, the number to be recommended for election in future would be seventeen. This new version of a particular statute takes us in retrospect to a very early period, namely, 1682, when it was decided that "Every person that would propose a candidate shall first give in his name to some of the Councell, that so in the next Councell it may be discoursed *vivâ voce* whether the person is known to be so qualified as in probability to be usefull to the Society. And if the Councell return no other Answer but that they desire further time to be acquainted with the gentleman proposed, the Proposer is to take that for an Answer". Repeal this reading occurred in 1728, the substance of alteration being that persons for election should first be proposed at a meeting of the Society, approved by the council, and recommended by three members, at least one of them a member of council. Soon after (1730) there was another change, mention of council being omitted, the requirement being that every person to be elected should be proposed and recommended at a meeting of the Society by three or more members, and qualifications were necessary to be set forth. The several elections of individuals were by ballot, not immediate, but at intervals.

IN 1830, no fewer than forty-two fellows, on a home list, were elected to the Royal Society between January and December (within these months, by the the way, Charles Darwin and J. J. Sylvester were included). Only four foreign members were elected. In 1841 the astonishing total of forty-four individuals was registered for the fellowship, whilst not a single foreign member appears in the list. In 1847 the number elected dropped to twenty-three, a result indicative, one may surmise, of impending changes in the mode of entry. In 1848 a drastic alteration in the system of the annual election came into operation, due to the regulations adopted the previous year. Fifteen candidates were duly selected; actually there were fourteen persons only who took up fellowship in that year. The meeting was notable as being the occasion of the valedictory address of the Marquess of Northampton, who had served ten years as president. It was already known that the latter held strong objections to the innovation, and he did not fail to express them in the course of his address. We have referred above to the fact of the election of only fourteen individuals. The president stated that—"It is rather a singular circumstance, that, since our selection was made, one of the gentlemen whom we had chosen, Mr. Syme, should have withdrawn his name. . . . The possibility of occurrence of such a case had not arisen in the minds of the former council when the new rules were framed, but it may perhaps be considered next year whether it ought to be provided against, or whether it is likely to occur so seldom as not to require any special provision." It is of interest to add that this "Mr. Syme" was James Syme, the eminent Scottish surgeon, to whom Joseph Lister had early acted as house-surgeon at Edinburgh, and whose daughter Lister afterwards married.

THE considerations which to-day bear upon the present slight increase in numbers admitted annually to the Royal Society may be briefly given; they are, however, recognised generally. The advance of science during the past half-century has provided new aspects and new fields of knowledge. In course of time it has led to an almost exclusive nomination from the lists of candidates of those (in various departments) who are comprised in the broad category of research workers attached to home and overseas universities; coupled, in lesser measure, with others who have entered industrial technical organisations where the exercise of expert training is required. The issues arising from the recurrent claims underlying specialisation have long occasioned serious thought. It has been stated that the council was able at one time to bring in annually a proportion at least of distinguished men outside the academic or professional sphere, whereby, it was claimed, a useful discriminating leaven and freedom from standardisation was maintained. Although the new enactment changes the existing situation in the annual election of candidates for the fellowship, it does not appear to involve abandonment or modification of the statutory provision of 1902, which, while it repealed an old rule for the election (at any time) of privy councillors, gave the council power to recommend to the Society for election, in alternate years, two persons who either have rendered conspicuous service to the cause of science, or are such that their election would be of signal benefit to the Society.

BY 255 votes against 225, the House of Commons has confirmed the Government's decision to allow the Dyestuffs (Import Regulation) Act to lapse in January next. Sir P. Cunliffe-Lister opened the debate on Dec. 4 by moving an amendment to provide for its extension for five years; the matter, he said, raises grave national issues, and is not merely a question of free trade. The industry is in origin British, and it has already once been lost to German foresight and wisdom; that loss was, at the outbreak of War, about the greatest handicap with which we had to contend. Sir H. Samuel, while admitting the possibility that foreign competitors might make the purchase of certain dyes dependent on the acceptance of dyes of cheaper quality, and that by selling at low prices they could stop valuable work in research and development now being pursued in Great Britain, nevertheless found no reason why the measure should be extended; his views were, he said, based mainly on the report of the Dyestuffs Industry Development Committee, to the effect that the building up of a substantial dye industry under the protection of the Act has temporarily laid a serious burden on the user of dyes. The President of the Board of Trade, Mr. Graham, said that the problem on which the

Government had to pronounce was the balance of advantage, and they were satisfied that the dyestuffs industry could continue in perfect strength and safety. The fact that the industry is able to offer virtual guarantees concerning price and quality is an indication that the central part of the case for protection has gone. He could not bring himself to believe that the industry will either collapse or operate under very great difficulties, because there has been a considerable measure of concentration of production. He was advised that there may be an agreement or understanding between British and German producers, and that that agreement may well be independent of whether the Act continues or lapses.

MR. GRAHAM, in the course of his speech on the Dyestuffs Act, referred to a memorandum on the subject submitted by professors of chemistry in the universities of Great Britain, in which the fear was expressed that if the industry is weakened by the lapse of the Act, they would lose a great deal of the advantages of training in research and of the effort to link science and industry together. He replied that it would be the duty of the Government to see that research is fully safeguarded; he suggested, for example, the formation of a research association under the auspices of the Department of Scientific and Industrial Research. Until more is known as to the proposed method of implementing Mr. Graham's promise, no useful comment can be made. Sir John Simon said that everyone would agree that the Act has produced a very efficient industry, that it has very materially promoted research, and that it has done something to develop British science; he advocated some continuance of the Act pending an effective inquiry. Mr. Henry Mond said that dye makers would be perfectly satisfied if this suggestion were adopted. There are altogether 10,000 known dyes, some 4000 being in current use, and about 2500 are made in Great Britain. Extension depends on the supply of trained scientific workers, and it would be impossible to provide the necessary school for the purpose until there is a well-established and a sound organic chemical industry. The future of industry is based upon the organic chemical industry. Mr. Wise expressed disappointment that the Government had not taken the opportunity to review the whole position in regard to dyestuffs, continuing to give to this vitally important trade a measure of protection in a non-fiscal sense which would enable it to develop what is a key-industry, and using the occasion to acquire for the benefit of the community a much greater control over the operations of a tremendously powerful corporation. Major Tryon regretted that, at a time when so many great problems in the dyeing industry alone are unsolved, the work should be broken up and part of the staff disbanded; it would set back a great experiment in the infinite field of undiscovered science. The debate was concluded by the Secretary for War, Mr. Shaw; no one, he said, was against any reasonable expenditure on research needed for guaranteeing the safety of the country, but those who want research should pay for it.

THE commemoration in London of the centenary of the death of Simon Bolivar, whose name is written so large across the geography of South America, and who died on Dec. 17, 1830, has been organised by a committee of the diplomatic representatives of Bolivia, Colombia, Peru, Ecuador, and Venezuela, together with the Spanish ambassador and others. The programme is to include a requiem Mass in Westminster Cathedral on Dec. 17, and the laying of wreaths at the Cenotaph in remembrance of the British soldiers who fought in Bolivar's army, and at the statue of Canning, who was the first to recognise the free States of South America. A commemorative tablet will also be unveiled in Apsley House, where, in 1810, Bolivar, representing the *Junta Suprema* of Caracas, met Marquess Wellesley, Secretary of State for Foreign Affairs. The following day a dinner is to be given by the Latin American Society of Great Britain to celebrate Bolivar's achievements and the old friendship between Great Britain and the republics he liberated. Bolivar, who was born at Caracas on July 24, 1783, came of a noble family of Venezuela, and after being educated at Madrid visited France and the United States. By 1811 he held the rank of colonel during the struggle for the independence of Venezuela, and thenceforth he was associated with the efforts which led to the formation of the republics of Colombia, Ecuador, Peru, and Bolivia, the last of which was named after him. After holding the dictatorship of Colombia, he resigned office on Jan. 20, 1830, and died the same year at Carthagena on his way into exile. His grave is in the cathedral of Caracas, the capital of Venezuela.

THE second triennial congress which is being called by the International Industrial Relations Association at Amsterdam in August 1931 should meet under favourable auspices. The Association was formed for the study and promotion of satisfactory human relations and conditions in industry, and thus has aims allied to those of the Industrial Welfare Society. The congress will consider the need for scientific adjustment of economic resources, production, and consumption, as essential to satisfactory human relations and conditions in industry. The present widespread unemployment position and lack of purchasing power, at a time when the world's production capacity and economic resources are greater than ever, give pertinence to an attempt to determine whether scientific methods can be used to achieve some balance between resources, production, and consumption. Recent discussions at the British Association meetings on the rationalisation of industry have stressed the human aspects of rationalisation. In the scientific study of the management aspects of rationalisation which is being carried out by the International Management Institute, the human factor and industrial psychology receive due attention, and the subjects chosen for research have included the selection and training of workers, accident prevention, methods of remuneration, welfare devices, etc. The Industrial Health Research Board has also strongly advocated the need for closer co-operation between psychologists and industry; whilst the Committee on

ndustry and Trade in its final report made recommendations for the scientific and practical investigation of the whole range of problems falling under the head of industrial fatigue, in the widest sense.

THE co-operation of scientific workers in this forthcoming congress is definitely invited, and the congress rds such workers an opportunity not merely of collaborating in the development of a technique of satisfactory human relations, including right working conditions, in industry, but also of assisting the formulation of economic policy, along the lines of knowledge place of caprice or prejudice. The participation of scientific workers in such a congress with representatives of employers and of labour should at any rate assist in relating science to practice and practice to science. The important problem of securing national administration in economic and industrial matters long rational and scientific lines appears, however, be rather outside the scope of the congress. Even the World Economic Conference of 1927 has thus far proved abortive so far as any real influence on Government policy is concerned. Once the management of industrial relations has been established on scientific lines, the international organisation and relationship industry may exert a more decisive influence on ational policy and administration, and scientific orkers cannot be indifferent to a congress which holds any prospect of promoting the leadership of ience.

A NOTEWORTHY recent lecture by Prof. R. Willstatter gives a searching analysis of the relations between fundamental scientific research and industry as seen in Germany at the present time. After stressing the debt of modern chemical industry to the scientific work of the universities, Prof. Willstätter analyses the activities of the industrial research laboratories, and pays tribute to the scientific merit of much of the development work carried out by such laboratories in fields which originally were opened up by purely scientific discoveries. The systematic investigation of a defined field—such, for example, as that of hypnotics, following on the discovery of veronal—to determine the substances possessing the most valuable combination of properties, even when carried out along lines of analogy, involves a high standard of scientific knowledge and frequently even more originality and inventive ability than the original and possibly fortuitous discovery. Such developments are as much among the greatest achievements of chemical industry as the elaboration of methods of large scale production for the new substances, and the success of such work depends more than anything else on the director of research.

EVEN in the development of large scale production the improvement of technique, industry has frequently been indebted to academic research, and Prof. Willstätter views with alarm the gradual estrangement between the large industrial firms and the universities which has developed with the growth of industrial organisations and the expansion of their research departments. There is not now the same personal contact between the universities and the leaders of industry, and in some quarters there is a definite tendency to disparage or resent suggestions coming from the universities. This tendency has already had an adverse effect on the financial position of research at the universities, and Prof. Willstatter urges that a more generous policy on the part of the industrial combines and a close contact between industrial leaders and the universities is required to stimulate the fundamental scientific research from which industry itself benefits so largely.

IN an inaugural lecture delivered at the London School of Economics on Dec. 2, Prof. Morris Ginsberg, who has succeeded the late Prof. L. T. Hobhouse in the Martin White chair of sociology, reviewed the present position of instinct in the social sciences. He defended the conception of the instincts as inborn impulses serving the root interests or basic needs of the organism, of which they must be regarded as limitations or specifications. The attempt to reduce instincts to compound reflexes fails, first, since the component parts of instinctive behaviour admit of varied combinations in a series which as a whole has unity and continuity, and secondly, since no adequate account can be given of mental development on the basis of the reflexes alone and their conditioning. The function of intelligence in relation to instinct is (1) to clarify and render explicit the ends of the inborn impulses; (2) to detect relevant relations between the actual situation and the ends; (3) to systematise the ends of the impulses into comprehensive purposes. The objection to instincts as occult forces is based on a false view of causality, which properly interpreted does not imply any notion of mysterious efficacy. That no satisfactory classification of human instincts has yet been produced is true, but irrelevant as an argument against them. None of the critics has in the end succeeded in dispensing with the instincts. Proceeding to a survey of the use made of instinct in social psychology, Prof. Ginsberg showed that: (1) There has been too much readiness to refer highly complex phenomena to single instincts. (2) The instincts have been incorrectly conceived as separate 'forces', thus ignoring the conational continuity of the self. (3) Stress on impulse has led to a disparagement of reason; in truth, impulse and reason are inseparably intertwined. (4) The accounts which have been given of the psychology of morality, of the basis of social life, and of sublimation appear to require restatement in terms of a more adequate definition of the relation between the root interests and the specific impulses which serve them.

RECENT discussion of the antiquity of man in East Africa has served to direct attention once more to the importance of the 'Oldoway skeleton' found by Dr. Hans Reck in the northern part of Tanganyika Territory in 1914. The evidence, geological, palæontological, and anthropological, afforded by this discovery must now be viewed in the light of Mr. Leakey's work in Kenya. The data for such further consideration are furnished by a valuable study of the skeleton and the attendant conditions of its discovery communicated to the Royal Anthropological Institute by

Dr. Reck and presented at a meeting held on Nov. 25. The Oldoway geological series consists of seven horizons, of which the fifth is a fossiliferous bed in which were remains of a variety of *E. Antiquus*, previously known only from Europe and the Nerbudda deposits, and human remains. Above this was a red-earthy deposit, root-infested and therefore undisturbed. The skeleton itself was found only a little above the horizon of *E. Antiquus*. The bones were not highly mineralised. Dr. Reck is now inclined to correlate Oldoway man with Elmenteita man found by Mr. Leakey in Kenya; but he differs from Mr. Leakey on the point of chronology, on the ground that only one pluvial period is represented at Oldoway. He also holds that it is not yet possible to correlate the fauna with that of Kenya. Mr. Leakey himself, on the other hand, detects a non-conformity between the Oldoway sixth and fifth beds suggestive of a temporary land surface. He is inclined to equate the Oldoway bone-bed with the upper part of his 'Gamblian'. It is evident that more field-work is necessary before any definite conclusion can be reached; but if Dr. Reck should be able to pay his projected return visit to Oldoway in Mr. Leakey's company important results may be expected to follow.

ON Dec. 5 the extension of the new spirit building of the British Museum (Natural History), which has been erected out of funds provided by the Empire Marketing Board for the use of the Department of Entomology, was formally opened before a large gathering of entomologists and others interested in the work of the Museum. Nearly four years ago the Board realised that the task of combating insect pests, the depredations of which so grievously hamper commerce either by directly attacking the raw material or the commodities resulting from it, or by injuring the health of the workers, was seriously impeded by the congested condition of the Department of Entomology, which rendered it impossible for the insect collection to be properly arranged and to be readily available for study. Accordingly the Board, in response to the request made by the Trustees of the British Museum, decided to devote an appreciable sum for erecting a suitable building, and in the end about £26,000 was expended. On consultation with the architects of the Office of Works it was decided to be preferable to add a permanent building rather than one which might have to be pulled down as the Museum expanded. For that reason about one-half of the west wing of the new building, which had been provided eight years ago for the collections kept in spirit, was added. It has been adapted to the use of the Department of Entomology: large windows have been pierced in what will eventually be the blank walls of the storerooms, and the mezzanine floors of those storerooms and one wall of the future corridor have been omitted.

THE proceedings were opened by the Director of the Museum, Dr. C. Tate Regan, who directed attention to the importance of insects in human affairs. He said that the collection of insects in the Museum numbers some six million specimens and has outgrown its accommodation; the Empire Marketing Board took no narrow view of its duties and realised the intimate relation of the work of the Department of Entomology to health, agriculture, and commerce. Mr. Ormsby-Gore, M.P., who was chairman of the committee when the Board made the grant, emphasised the necessity for adequate scientific research in the development of the British Empire. The Archbishop of Canterbury, as chairman of the Trustees of the British Museum, expressed their thanks to the Empire Marketing Board and the Office of Works for their help, the value of which could not be exaggerated. The association between the Museum and the Government in the development of the Empire and its resources was appreciated. He hoped that the flow of fit persons would be quickened in the schools and universities to serve the Empire by research in every branch of science.

IT is easy to think of many ways in which the light sensitive properties of selenium can be utilised in the industrial world. When, however, an attempt is made to realise them in the research laboratory and later in the development department of a manufacturing works, many difficulties have to be overcome. We learn from the *Electrical Times* of Oct. 16 that the Radiovisor Parent, Ltd., of 26 Coventry Street, W.1, has surmounted many of these difficulties and perfected apparatus which is being employed commercially for various purposes. The most important application is to sound films. By means of a suitable electric bridge and an amplifier, it is now possible to give faithful reproduction of sound over the working range of frequencies. Another application is to the control of street lighting. There are some fifty street lamps in the Mortlake area, Surrey, which are controlled in this way, and they are also in use in several towns. Another application is a controller which regulates the lighting of clocks, telephone kiosks, signs, etc. Queensbury Church, a well-known landmark in Yorkshire, standing 1300 feet above sea-level, now has its four clock faces illuminated by electric lamps which are controlled automatically by a selenium unit. As selenium operates on both infra-red and ultra-violet light, it can be used as a burglar alarm. A special infra-red lamp is concealed and directs its beam across the object to be protected. Any interruption of the beam by the hand or body of an intruder instantly sets in action a warning device, either a red lamp or an alarm bell. Devices are made for indicating the presence of smoke in ships' holds. They are also officially recognised for the timing of racing motor cars and for dog racing. We understand that many other uses of the radiovisor bridge are being developed.

A LECTURE with novel demonstrations was given by Mr. Grace to the New York Electrical Society last month. It proved so interesting that it was repeated on three nights and very many people were unable to obtain admission. The first experiment was the 'projection' of speech directly into the human brain. This was done by transforming speech into a high

frequency current. The lecturer took hold of one electrode, his assistant held the other, and they placed their free hands against the ears of one of the members of the audience. The latter immediately heard music or speech, although no sound could be heard by any other person present. The explanation given was that the ear drums and surrounding tissues acted like the plates of a condenser receiver, the resulting vibrations of the ear drum due to electrostatic forces producing the sensation of intelligible sounds. Another experiment was the 'inversion' of speech. Ordinary speech was inverted so that the high notes became the low notes and vice versa. This inverted speech is quite unintelligible, but was reinverted into intelligible speech by suitable apparatus. In inverted speech, telephone sounded like 'play-o-fine' and company like 'crink-a-nope'. This method is already in use in transatlantic radio telephony to prevent unauthorised listeners from understanding the messages. Colonel Marshall, an engineer who had the misfortune to lose his larynx and had been provided with an artificial one, gave a short address to the audience from his home in California over the transcontinental telephone, on his method of controlling the floods in the valley of the Mississippi. A very successful demonstration was given of an ordinary carbon arc as a loud speaker. The method was originally discovered by Graham Bell, but hitherto the sound has been too faint. By using amplifiers, Mr. Grace made the talking arc almost as loud as the best modern loud speakers.

ON Dec. 4 a public lecture on "The Evidence of Astronomy and Technical Chronology for the Date of the Crucifixion" was delivered at Oxford by Dr. J. K. Fotheringham, reader in ancient astronomy and chronology in the University. Definite historical data, he said, limited the possible years to the period A.D. 27–34. Of these, the Jewish astronomical reckoning excluded all but the years 29 and 33. The year A.D. 29 was advocated by the late Prof. C. H. Turner, but Dr. Fotheringham gave reasons for dissenting from this view and also from that of the late Sir William Ramsay. He himself inclined to the date of April 3, A.D. 33, as offering fewer difficulties than any other. A point in his argument was the fact that the Jews reckoned the new moon from its first visibility; not from its astronomical position.

A NEW society has been founded in Paris for the scientific study of Africa. The president of the Society, which is to be known as the Société des Africanistes, is to be General Gouraud, and M. P. Lester will act as general secretary. Monthly meetings of the Society are to be held for the reading of papers, and a journal will be issued which, in addition to original memoirs, will contain reports of the proceedings at the meetings, notes and news on things African, and a bibliography of current literature on African ethnology. The Society will consist of patrons subscribing 2000 francs, life members subscribing 1000 francs, and ordinary members who pay an annual subscription of 50 francs, or if residing abroad 60 francs, with an entrance fee of 15 francs. Requests for further information and subscriptions should be addressed to M. P. Lester, General Secretary, 61 rue de Buffon, Paris.

MR. P. H. GRIMSHAW has been appointed Keeper of the Natural History Department in the Royal Scottish Museum in succession to Dr. J. Ritchie, who has recently been appointed to be Regius professor of natural history in the University of Aberdeen.

PROF. WILHELM SCHMIDT took over the chair of geophysics in the University of Vienna and the directorship of the Zentralanstalt für Meteorologie und Geodynamik, Vienna, on Nov. 25. He succeeds Prof. F. M. Exner, who died on Feb. 7 last.

THE following appointments have been recently made by the Secretary of State for the Colonies to the Colonial Agricultural and Forest Services: Mr. A. J. Findlay, assistant director of agriculture, Nigeria, to be deputy director of agriculture, Nigeria; Mr. V. F. Olivier and Mr. A. F. W. Sheffield, to be superintendents of agriculture, Nigeria; Mr. P. A. Allison, Mr. A. F. Ross, and Mr. B. E. A. P. Urquhart, to be assistant conservators of forests, Nigeria.

THE Institution of Automobile Engineers has for some years past been giving advice to parents as to how their sons can enter the automobile industry. This practice has been elaborated, and information can now be obtained of the possibilities of apprenticeship in works in any particular neighbourhood. No charge is made by the Institution, the staff of which can be consulted by appointment, by writing to the Institution, Watergate House, Adelphi, London, W.C.2.

THE War Office announces that there are vacancies for commissions in the Supplementary Reserve of Officers as ordnance mechanical engineers in the Royal Army Ordnance Corps. In addition to qualifications as to character, medical fitness, nationality, etc., candidates must be less than thirty years of age for appointment as subalterns and less than thirty-five years of age for appointment as captains, and must also be fully qualified mechanical engineers. Preference will be given to bachelors of science (Engr.), Whitworth scholars, graduates, and associates of the Institutions of Civil, Mechanical, or Electrical Engineers. Candidates will not be required to undergo training in peace-time, but will be liable to be called out on service when the Army Reserve or any part of it is called out by Proclamation. In return for their obligation, officers will be granted an annual gratuity of £25, payable in arrear. Particulars can be obtained from the Under-Secretary of State for War (A.G.9), the War Office, London, S.W.1.

"EARLY Photomicrographers" is the title of an article by C. H. Oakden in Watson's *Microscope Record* for September (No. 21). The honour of being the first photomicrographer is ascribed to the Rev. Joseph Bancroft Reade (1801–1870), who in 1837 obtained prints of the image thrown by a 'solar' microscope upon paper treated with silver nitrate and infusion of galls, fixing the print with hypo made by himself.

IN the autumn issue of *Sunlight* (Vol. 2, No. 3), the journal of the Sunlight League, a table is given of the

average daily readings for August of the intensity of ultra-violet radiations at various localities in the British Isles. The figures illustrate the high intensity which these radiations sometimes attain in England, figures of about 8·7 being obtained at Cleethorpes and Lowestoft, and of 7·75 at St. Ives and Ventnor. They also illustrate how much the intensity of the radiations must depend on climatic conditions prevailing, for while the figure for Clacton is about 7·0, at Southend-on-Sea it was only 1·0 – the lowest record of all stations. Among other articles, Dr. Kathleen Vaughan writes on the value of sunlight and the open-air life for healthy motherhood.

A SHORT list of nearly 300 books on British and foreign birds has been received from Messrs. Francis Edwards, Ltd., 83 High Street, Marylebone, W.1. It includes a few scarce items.

MESSRS. Wheldon and Wesley, Ltd., 2 Arthur Street, W.C.2, have just circulated a list (New Series, No. 23) of many second-hand works, classified under the headings of periodicals and publications of learned societies, miscellanea, zoology, botany, medicine, sport, and addenda. It is obtainable upon application.

WE have received from Messrs. A. Gallenkamp and Co., Ltd., a catalogue of apparatus for testing petroleum and its allied products. The list, which covers 52 pages and is well illustrated, covers nearly all the standard apparatus required for testing such materials, but the Tate specific gravity bottle seems to have been overlooked. The prices are all given.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned: – Two inspectors of aircraft under the Union of South Africa – The Secretary, Office of the High Commissioner for the Union of South Africa, 73 Strand (Dec. 16). An assistant chemist at the sewage disposal works of the County Borough of Reading – The Town Clerk, Town Hall, Reading (Dec. 18). A head of the chemistry department of the Plymouth and Devonport Technical College – The Secretary for Education, Education Offices, Plymouth (Dec. 20). An inspector of alkali, etc., works, under the Ministry of Health – The Director of Establishments, Ministry of Health, Whitehall, S.W.1 (Dec. 20). A junior lecturer in the department of pathology of the University of Liverpool – The Registrar, The University, Liverpool (Dec. 24). A whole-time abstractor and translator at Sheffield, under the Safety in Mines Research Board – The Under Secretary for Mines, Establishment Branch, Dean Stanley Street, S.W.1 (Dec. 31). A professor of biochemistry at the Indian Institute of Science, Bangalore – Prof. F. G. Donnan, University College, Gower Street, W.C.1.

Our Astronomical Column.

Magnetic Disturbance, Dec. 3-4, 1930. – A considerable magnetic disturbance, falling into the category of a small storm, occurred on Dec. 3–4. The storm began with a characteristic 'sudden commencement' on Dec. 3 at $1\frac{1}{4}^h$, but apart from this the oscillations of the needles were not appreciable until about thirteen hours later, the most disturbed part of the traces being between 15^h and 22^h on Dec. 3. The range in Declination at Greenwich was 51′. At the time of the storm there was only a smallish sunspot, of area 130 millionths of the sun's hemisphere, a little way past the central meridian. Spectroscopic observations, which greatly increase the range of detection and scrutiny of solar eruptions, were impossible owing to fog or overcast skies. The recent magnetic storm appears to be the largest since that of Mar. 11–13, 1929, though during 1930 a number of disturbances of somewhat lesser intensity have occurred.

Stellar Parallaxes. – *Scientia* for October contains an interesting paper by Prof. S. A. Mitchell, describing the remarkable advance that has been made in recent years in determining the distances of the stars. It is less than a century since Bessel found the distance of 61 Cygni; it was not until the present century that the work was placed on a reliable basis, and the probable error of a parallax reduced to about one-hundredth of a second. Prof. Mitchell states that about three thousand accurate parallaxes have now been found; his own observatory (the Leander McCormick) is the leader with a thousand parallaxes; each of these rests on some fifteen plates, taken at about five seasons six months apart.

Reference is made to Prof. Schlesinger's measures with the Yerkes refractor twenty years ago; since it was not a photographic telescope, yellow screens and isochromatic plates were necessary. The use of colour screens has the advantage of reducing the error arising from the different colours of the stars, which cause difference in refraction; this difference is also reduced by taking all parallax plates near the meridian, and using only the parallax in right ascension. The systematic errors of the results of the leading American observatories were shown by Stromberg and van Maanen to be of the order of 0·003″, which is the angle subtended by one inch a thousand miles away. Other methods have been devised for estimating the distances of objects too remote to show any parallax: spectroscopic parallaxes, the relation between period and absolute magnitude for Cepheid variables, Eddington's relation between mass and absolute magnitude, and the strength of the lines in the spectrum that are due to interstellar calcium; but all of these methods need a number of reliable parallaxes in order to calibrate the curves. Thus the spiral nebulæ are distant millions of light-years, but this estimate is ultimately based on the parallaxes of stars that are only distant about a hundred light years.

Comets. – *Beob. Zirk.*, No. 42, contains observations of comets 1925 II. (Schwassmann-Wachmann) and 1927 IV. (Stearns) made during September and October with the large reflector at Bergedorf, by Dr. W. Baade. Their magnitudes were 17 and 17·5 respectively. These were taken at an interval of $5\frac{1}{4}$ years after perihelion for the first comet, and $3\frac{1}{2}$ years for the second. It will be remembered that the orbit of 1925 II. lies entirely between those of Jupiter and Saturn, its period being about fifteen years. There appears to be a fair prospect of its being observable round the whole of its orbit, which would be a new cometary record. 1927 IV. is affording a record of another kind. It is now outside the orbit of Saturn, and has probably been observed at a greater distance from the sun than any previous comet. Halley's comet was lost soon after crossing the orbit of Jupiter.

Research Items.

Roman Britain.—An account by Dr. R. E. Mortimer Wheeler of the first season's excavations at St. Albans, which appears in *Discovery* for December, admirably summarises the chief points of interest. It was thought that Verulamium, which at one time was the nearest approach to a metropolitan city and the only town in Britain dignified with the title of *municipium*, might well supply evidence of exceptional importance in its bearing upon Romano-British culture and organisation. This has been confirmed already in a striking manner. The 'London Gate', for its size and what must have been imposing appearance, is compared by Dr. Wheeler to the great continental gateways or triumphal arches such as have been found at Arles and Autun. The defences of the city are also impressive, consisting of fosse, wall, and reinforcing bank totalling a width of some 165 ft., and even in one part running to 265 feet. Light is thrown upon economic conditions in the city and its possible relations with Germany by the excavation of a dwelling-house and another building, probably a shop. The house was rebuilt at least thrice during the Roman occupation, and its successive phases show the rise to prosperity and the subsequent decline of the town. Exploration outside the city wall has revealed a cemetery and a prehistoric earthwork. The purpose of the latter is not yet clear, but one of the alternatives suggested is that it may be the site of the settlement of Cassivelaunus, the most important centre of southern Britain in the first century A.D. These latter discoveries have added thirty acres to the area to be investigated, the site within the Roman walls being 200 acres.

The Wishram.—Although the Wishram were one of the tribes earliest met by European explorers of the Columbia River, and their trading establishment was of great importance in the development of the north-west of America, their culture is very little known. Only a few of the Wishram now survive, some on their original site on the Columbia River opposite the Dalles, others on the Yakima reservation in Washington. Information obtained by Dr. E. Sapir in 1905 and Mr. Leslie Spier in 1924 and 1925 from the survivors is embodied in "Wishram Ethnography", Vol. 3, No. 3, of the University of Washington Publications in Anthropology. The Wishram were the easternmost Chinookan tribe on the Columbia River, and their language an Upper Chinook dialect. Dislocation of the tribe began at the end of the eighteenth century as the result of tribal movement so early as, or even earlier than, 1750, which brought the Sahaptin into Washington State. The Wishram depended primarily on fishing for their livelihood, and their culture was entirely a river culture. Fishing was supplemented by seed and root gathering. Hunting the deer and other game took an entirely subsidiary place. They lived in villages on the northern side of the Columbia River, roughly from White Salmon River to Ten-Mile Rapids above the Dalles. Their houses were semi-subterranean lodges built over a circular pit, or mat lodges. The earth-lodge accommodated from one to half a dozen families. As elsewhere on the north-west coast of America, class feeling was strongly marked. There were three classes, besides slaves. The classes were based on wealth; but chiefs were not always among the wealthiest class. There were also war chiefs. The chiefs had considerable power and were implicitly obeyed. They adjudicated in murder cases, assessing fines or other punishment. In cases of murder by witchcraft through a shaman, the shaman was not held culpable, but only the man who employed him.

Tunnies.—Because of their economic importance as food fishes, allied with their peculiar habits, the tunnies have formed the subject of a vast literature, spread over a period of fully two thousand years. Active researches into their life-histories and abundance still continue, and recent workers have felt the need of a reasonably complete bibliography—a need which is now fully met by "A Bibliography of the Tunas", by Genevieve Corwin (*Fish Bulletin* No. 22, Contribution No. 87, from the California State Fisheries Laboratory, Terminal Island, California; 1930). The compiler has endeavoured to find and to catalogue all works written previous to the close of 1929 dealing in any way with the five large tunnies—*Thunnus thynnus*, *Neothunnus macropterus*, *Germo alalunga*, *Euthynnus pelamis*, and *Sarda chiliensis*. All the papers listed, with only a few exceptions, have actually been consulted, and after the title of each a brief note is appended indicating its main theme and general scope. These notes add greatly to the value of the bibliography. A list is given of all the abbreviations used for periodicals cited, and a classified index of subjects facilitates reference to any point upon which information may be desired regarding these fishes.

***Chirocentrus* and its Eggs.**—In *Treubia*, Vol. 12, 1, 1930, Dr. H. C. Delsman describes two fish eggs which, although easily distinguishable, give rise to closely similar larvæ ("Fish Eggs and Larvæ from the Java Sea"). Both belong to the genus *Chirocentrus*, the 'Parang-Para' of the natives. One of the larvæ is slightly longer than the other and has more myotomes. This interesting find is in accordance with the fact that Bleeker in 1852 distinguished two species, *C. dorab* and *C. hypsalosoma*, whilst other authorities found only one. Dr. J. F. Hardenberg, in another paper in the same number of this journal ("Some remarks on the Genus Chirocentrus (Cuv.)"), fully confirms the separation of the two fishes. Both are long and slender pelagic species, attaining the length of 90 cm. or more. *C. dorab* is the more slender of the two, with more vertebræ than *C. hypsalosoma*, larger scales, and other differences in the proportions of the various parts, the distribution being slightly different, although both species, old and young, and also the eggs, may be found together.

Antarctic Free-living Nematodes.—Dr. N. A. Cobb describes a large number of these worms, which are extremely abundant in the Antarctic marine waters, in a paper entitled "Marine Free-living Nemas" (Australasian Antarctic Expedition, 1911-14, under the leadership of Sir Douglas Mawson: Scientific Reports. Series C—Zoology and Botany. Vol. 6, Part 7, June 1930). They belong to twelve genera, collected from muddy sediment, three fathoms, Commonwealth Bay (Adélie Land), the larger forms from amongst the roots of brown algæ. A formula of measurements and signs is introduced in the systematic work, which conveys a large amount of information compressed into a very small space, and there is a key to the fifteen species involved. These Antarctic nematodes have several features in common. There is one new genus, *Hyptiolaimus*, created for the new species *cephalatus*, which may be related to *Oncholaimus*, and eight new species besides this. It is interesting to learn that one of these, *Monohystera naviculivora*, as its name implies, is a diatom feeder, especially eating *Navicula*. Sometimes the intestine is crowded with the frustules, many of which are as long as the width of the worm and half as wide as its head end; 150 diatoms have been seen in one individual.

The Walnut Tree in England.—Two papers in the *Journal* of the Royal Horticultural Society for September deal with this subject. Mr. H. Spence discusses the qualities of the timber and the cultivation of the walnut in France and California. He also comments upon the quality of the nuts obtained from the various isolated trees grown in Great Britain, so far as recent inquiries enable this to be gauged. Mr. A. W. Witt discusses the vegetative propagation of the tree under English conditions as ascertained by preliminary trial at East Malling. At present, grafting upon seedling stocks of *Juglans nigra*, or the common English walnut, seems to be most practicable, grafting under glass proving most successful. Stocks are also being raised vegetatively, the parent plant being planted in open, sandy ground, layered, and the buds covered with an inch of soil whilst still dormant. The young shoots thus etiolated afterwards root readily.

The Cultivation of *Pyrethrum*.—Of recent years knowledge has been gained as to the conditions necessary to observe if pyrethrum sprays are to be efficacious. Tutin has a paper upon its method of employment in the Annual Report of the Agricultural and Horticultural Research Station, Long Ashton, 1928, and there seems little doubt that this substance may prove a most valuable insecticide; at present it is one of many agents that are being tried out against the tsetse fly in Africa. An article upon its cultivation, in the *Bulletin of the Imperial Institute*, **28**, No. 3, 1930, is therefore very timely. Known for many centuries in Persia, the plant itself, and the powder ground from the flowers, were introduced into Europe early in the nineteenth century. In 1881, the Dalmatian species, *Chrysanthemum cinerariaefolium* Vis., was introduced into Japan, where its cultivation flourished apace, especially around Hokkaido, and 70 per cent of the world's yield is now claimed by Japan. This article, by the British Vice-Consul at Seoul, Japan, shows that the great development of this crop in Japan resulted from War conditions, when cultivation of the plant was almost suspended in Austria. A very good quality of flower is produced in Europe, and subsequent years may see a development of the European product again, especially if the insecticidal use of the product undergoes wide development.

Stratigraphical Position of the Coutchiching Series.—In the neighbourhood of Steep Rock Lake, Ontario, a series of schistose Pre-Cambrian sediments occurs, bordered on the north by Keewatin basic volcanics and on the south by intrusive granite. To the west these schists continue towards Rainy Lake, but to the east they gradually finger out and are lost in the granite. They have been alternatively correlated with the Coutchiching (below the Keewatin) and with the Seine (above the Keewatin). In the *Jour. Geol.*, p. 521, 1930, J. E. Hawley presents evidence to show that although the schists appear to dip beneath the Keewatin, the contact is one of nearly flat shear-faulting, in which case the stratigraphical evidence of relative age becomes ambiguous. From the larger structures it is thought probable that the disputed series is of post-Keewatin age. This does not, of course, imply that genuine Coutchiching schists may not exist in the Rainy Lake area.

Mineral Industry of Alaska.—The mineral industry of Alaska, if it has not been the mainstay of the country, has at least contributed largely to its economic development. Some thirty years of geological survey, fostered by the Federal Government of the United States, has produced results of inestimable value to the prospector, miner, and business executive, and abundant information relative to the origin, character, distribution, and extent of the various ore deposits is available. The total value of the mineral production in 1928 (*Bull.* 813-A, United States Geological Survey) was more than fourteen million dollars, furnished chiefly by gold and copper. There is also some silver, tin, lead, a little platinum, coal, and petroleum, while marble, gypsum, etc., are important. The gold is obtained from lode mines and placers in about equal quantities, the principal lodes occurring in the south-east. The Yukon Basin still figures as the prominent placer territory, though a considerable quantity of the metal comes from placers in the Seward Peninsula. Practically all the copper is derived from two mines in the Copper River region and from Latouche Island. The chief source of silver is the copper lodes, though it is also obtained from the gold lodes and placers. Lead is recovered as a by-product in the course of gold and silver mining. Platinum, together with palladium, osmium, and iridium, has been found sporadically in both lodes and placers. Tin has been mined from veins and mineralised rocks occurring in the Seward Peninsula, and the comparatively small tonnage finds its way to Singapore for reduction. The output of bituminous and anthracitic coals has increased, and in 1928 more than 126,000 tons were produced. Petroleum is mainly confined to the Katalla field. It is refined on the spot, and the products, gasoline and distillate, find a ready sale for the boats of the fishing fleets. This last industry has not apparently justified the optimism originally expressed or the vigorous search for fields in the past. Imports of oil from the United States supply most of the needs of the inhabitants.

Intensity of the Auroral Line.—It is possible, by the use of a special colour filter, to isolate effectively that part of the light from the night sky which extends for about 200 A. round the green oxygen auroral line λ5577 and so to follow variations in its intensity. Lord Rayleigh, in the November number of the *Proceedings of the Royal Society*, has given an account of an attempt to make these relative measurements absolute, which has been accomplished by determining the absolute values of the numbers in his arbitrary scale of intensities, by reproducing them with the illumination from a standard incandescent lamp. Actually the light from the sky which was transmitted by the filter used consisted only in part of the auroral line, this being superposed upon a continuous background, the relative intensity of which is known to vary considerably. Taking the fraction of the light transmitted by the filter and due to λ5577 to be 0·37, the brightness of this line in the sky was found to be approximately 3×10^{-5} candles per square metre. The energy required to maintain this is 6·4 ergs per second per square metre, and the number of atomic transitions required to supply this energy 2×10^{12} per second per square metre. These numbers are known to vary from time to time, and to be quite definitely rather approximate, but should be of much value in testing theories of the light emission from the upper atmosphere.

High Velocity Positive Ions.—Work is now in progress in several laboratories on the production and properties of particles of high speed, the aim of such experiments being to provide electrical sources to replace radio-active sources of α-particles and β-particles. A preliminary report on some work of this nature, which is being performed with positive ions in the Cavendish Laboratory, is given by J. D. Cockroft and E. T. S. Walton in the November number of the *Proceedings of the Royal Society*. The problem can be

divided into two parts, so far as the generation of the high-speed particles is concerned; first, the production of a stream of ions in a form suitable for acceleration, and secondly, the method of acceleration. The source of ions which has been used is a canal ray tube, the cathode of which is pierced with a narrow tube from which emerges a mixed beam of protons and molecular ions, and the acceleration of these has been brought about by a potential of 300 kilovolts produced by rectifying the output of a low-frequency step-up transformer. Many difficulties were, naturally, encountered in the course of the work on account of the high potentials involved. The electron tubes used to rectify the high potential had to be specially built, and were kept continually exhausted by a diffusion pump, the latter containing oil instead of mercury. The bulbs in which the ions were accelerated and the potential rectified were blown from a hard Jena 'molybdenum' glass, and, with their stems, were each approximately a metre in length, to minimise the chance of sparks passing externally through the air between the electrodes. It was found that the ion beam could be focused by suitable choice of the dimensions of the electrodes. Very little space is devoted in this paper to applications of the fast ions, but it is mentioned that a non-homogeneous radiation has been found to be produced when metals are bombarded by the stream of ions, the intensity of the radiation being approximately one ten-thousandth of that produced by a similar electron source at the same voltage.

Radiation Distribution of a Radio Antenna.—To the September number of the *Journal of the Institution of Electrical Engineers*, R. M. Wilmotte, of the National Physical Laboratory, contributes two papers on the radiation distribution which takes place from the antenna of a radio system. In the first paper, he obtains formulæ for this distribution from advanced theoretical considerations, and he shows how they can be applied in practice to the case of the beam antenna. He points out that even in complicated cases where we have an array of antennæ, it is possible to obtain solutions. In the second paper, he discusses experimental results on the radiation distribution in vertical planes from an antenna. The results were obtained by measuring in an aeroplane the strength of the received signals from an excited antenna on the ground. The position of the aeroplane was determined from the ground by means of a theodolite, and the signal strength was recorded on a cinematograph film. The results showed very definite maxima and minima, their positions being determined within a few degrees. But only rough values of the field strength could be obtained, as many experimental difficulties had to be overcome. In the case of low frequency, substantial agreement between theory and experiment was obtained. The radiation was also obtained for one of the beam stations of the Marconi Co. It was found that, owing to the sharpness of the beam, large discrepancies were sometimes observed. The average results obtained were, however, in good agreement with theory. It is concluded that the theory of radiation distribution is correct to a first approximation. The difficulties seem to be connected with the fact that in practice it is impossible to obtain a site which is theoretically perfect.

Hydrates of Hydrogen Fluoride.—In the October number of the *Journal of the American Chemical Society*, Cady and Hildebrand describe measurements of the freezing points of the system water + hydrogen fluoride, which indicate that, in addition to the solid hydrate $HF.H_2O$ previously known, the compounds $H_2O.2HF$ and $H_2O.4HF$ exist. The existence of two compounds with excess of hydrogen fluoride but none with excess of water indicates that hydrogen fluoride tends to assume a more complex polymerisation than water, and the formula $H_2O.4HF$ is in agreement with the existence of H_4F_4 as one polymer of HF. Berliner and Hann had suggested that this polymer exists, and had pointed out that hydrofluorides of amines have the general formula B.4HF. Other compounds such as KF.3HF and $MgF_2.2HF$ may be regarded as derivatives of H_4F_4, and if water behaves in a manner similar to the amines, one compound formed should be $H_2O.4HF$.

Filter-cloth from Nitrocellulose.—In an article in the *Chemiker-Zeitung* for Nov. 8, Dr. Hans Gradl of Munich directs attention to the suitability of nitrocellulose as a material for the manufacture of filter-cloth. The resistance of various textile materials to the corrosive action of acids and alkalis appears to depend upon the amount of nitrogen which they contain, and numerous attempts have been made to increase this resistance by increasing the nitrogen content of the fibre. Thus, cotton cloth has been nitrated after it has been woven, but the best results so far have been obtained by using cloth woven from an artificial silk consisting of nitrocellulose, containing 12 per cent. of nitrogen. This filtering material has given very satisfactory results during the last four years. It can be used to filter a 40 per cent solution of phosphoric acid at 90° C. without deterioration. It must be preserved damp, and the serious technical difficulties at first encountered in weaving it in this condition have been overcome. It can be cut into convenient shapes and sewn with nitrated thread.

New Inverted Metallurgical Microscope. The Beck Inverted Microscope No. 30 is constructed on the same principles as the Beck-Hadfield microscope. By fitting a collimating lens in front of the vertical illuminator, it has been found possible to replace the long optical bench of the original microscope by a short fixed base, which makes the apparatus much more compact and robust. Apart from the camera, which has a variable extension of 10 in., all the major components are fixed. Just sufficient movement is allowed in the position of the source of light and in the illuminator to ensure that critical illumination may be easily obtained under all conditions. The simplicity of the new design, and the omission of the *macro*-photography equipment, have enabled the makers to reduce the price of the complete outfit from about £350 to £220. The whole apparatus has been designed to stand hard wear, and once it is set up it should need little attention. The microscope stage is remarkably rigid, and the coarse adjustment, which moves the stage, can be clamped in any position. The fine adjustment carries the objective only, and acts smoothly. The changing device for the objectives is positive in action, and very satisfactory. The thin glass illuminator can be replaced easily by a prism, though the makers recommend the use of the former type. The apparatus was tested with specimens of fine pearlite, the laminations of which were so close together that they could just be resolved with the $\frac{1}{12}$ inch oil-immersion lens. When the specimen was examined visually, using the thin glass illuminator, the resolution was found to be excellent. The illumination was even, and the image was satisfactorily free from glare. The definition at about 1500 diameters was good and the field reasonably flat. When the prism was substituted for the glass slip, however, the image was, of course, brighter but the illumination decidely less even. The illuminant was a 'pointolite' lamp which has only about one-fifth the intensity of a carbon arc.

Aspects of Carbohydrate Metabolism.

III. SOME RELATIONSHIPS WITH PHOSPHORUS METABOLISM.

IT is now well known that esters of carbohydrate and phosphoric acid play an important part as intermediates in carbohydrate metabolism in both animals and plants. They were first obtained in the alcoholic fermentation of yeast; later they were found to play a part in the metabolism of muscle and other tissues. Phosphorus occurs in animal tissues in several other forms; for example, as ortho- and pyro-phosphate, as a constituent of nucleoproteins, and in combination with creatine in muscle. It is proposed in this review to discuss only certain aspects of the metabolism of phosphoric acid esters; the formation of hexose phosphate as a step in the production of lactic acid from starch by skeletal muscle has already been mentioned in a previous article (Nov. 8, p. 740). P. Eggleton has published a review on the rôle of phosphorus in muscular contraction, in which reference is made to the hexose phosphates (*Physiol. Reviews*, vol. 9, p. 432; 1929).

Resting muscles do not contain hexose diphosphoric acid; they can, however, glycolyse it and, in the presence of sodium fluoride and glycogen, synthesise it. The ester formed appears to be the same as that isolated by Harden and Young from yeast fermentations. W. T. J. Morgan has investigated its chemistry (*Biochem. Jour.*, vol. 21, p. 675; 1927; with R. Robison, *ibid.*, vol. 22, p. 1270; 1928). The first step was the formation of the methylhexoside-diphosphates, which were then separated into the α and β forms. The barium salts were hydrolysed with bone phosphatase (to which further reference will be made below), when the phosphoric acid was split off; further investigation, including estimations of the rotations before and after acid hydrolysis of the hexosides, and determinations of the methoxy group, indicated that the hexose present is fructose, probably γ-fructose. A tetramethyl hexose, having the same rotation as tetramethyl-γ-fructose, was also prepared; the constitution of the original acid is probably γ-fructose 1 : 6 diphosphoric acid.

J. Pryde and E. T. Waters have confirmed the presence of the diphosphate in muscle press juice after carrying out the fermentative re-synthesis; when this step was omitted, only a monophosphate was isolated, from the muscle of the rabbit, donkey, and goat, and this appears to be the ester of normal resting muscle (*Biochem. Jour.*, vol. 23, p. 573; 1929). The amount present in the muscles of the larger animals was less than in those of the rabbit, in which the yield was 0·13 per cent; it is possible that it is connected with the speed of contraction of the muscle. By oxidation of the hexose group with bromine and removal of the phosphoric acid by hydrolysis with weak sulphuric acid, a hexonic acid was obtained which was identified as gluconic acid. Ninety per cent of the hexose is an aldose, 10 per cent a ketose; from the formation of gluconic acid the former is presumably *d*-glucose.

The presence of phosphoric esters in different tissues suggests the presence of enzymes to synthesise and hydrolyse them; in fact, phosphatases are very generally distributed throughout the body, according to H. D. Kay (*Biochem. Jour.*, vol. 20, p. 791; 1926; vol. 22, pp. 855 and 1446; 1928). The enzymes can be extracted with chloroform water from the ground-up tissues, the extract being filtered through cotton-wool before use. They act upon hexose phosphates, glycerophosphates, and nucleotides; for quantitative estimation it is convenient to use sodium glycerophosphate in glycine-sodium hydroxide buffer at pH 8–9: the amount liberating 1 mgm. phosphorus in two hours at 38° may be called one unit. The enzyme is found in highest concentration in the mammal in the kidney and the mucous membrane of the small intestine: there is a close parallelism between its distribution and that of ereptase. Study of the reactions with the different substrates led to the conclusion that the same enzyme is responsible for the hydrolysis of each. In the case of the kidney, the enzyme is chiefly present in the cortex; there is more in the infant soon after birth than in the fœtus, and thereafter its concentration does not change much to adult life. It is capable of acting upon part of the phosphoric ester in the blood plasma. It has been suggested that its function is to hydrolyse this ester, which is then excreted as inorganic phosphate in the urine; but Kay, with R. T. Brain and P. G. Marshall (*ibid.*, vol. 22, p. 628; 1928), found that the excretion of phosphate was controlled by the level of the inorganic phosphate in the plasma, and not by that of the ester phosphorus. The low level of the latter in the plasma cannot be raised by administration of ester by mouth, though a temporary increase can be brought about by intravenous injection. On the other hand, the amount present in the kidney varies with its functional efficiency: thus it is markedly reduced in chronic nephritis in man and in acute uranium nephritis in rabbits (Brain and Kay: *ibid.*, vol. 21, p. 1104; 1927).

Both intestinal and kidney extracts show synthetic activity, provided high concentrations of the alcohol are used; sodium glycerophosphate was successfully isolated from the reaction mixture after allowing duodenal contents to act on sodium phosphate and glycerol for a week.

It may be mentioned that Kay has also found a pyrophosphatase in many mammalian tissues, with a distribution similar to that of the phosphatase described above; it hydrolyses pyrophosphate to orthophosphate. Its optimum pH is 7·2–7·8, in contrast to the range 8·8–9·3 of the orthophosphoric esterase.

The true phosphatase is of considerable interest; it can be conveniently extracted from young bones (rabbits) by soaking the split bone in chloroform water for some days, and filtering and evaporating the extract (M. Martland and R. Robison: *Biochem. Jour.*, vol. 23, p. 238; 1929). It can be purified by precipitation from water with alcohol and ether and extraction of the precipitate with 50 per cent alcohol; it cannot be dialysed or ultra-filtered, and is easily adsorbed. Its optimum pH is about 8·4; the initial rate of hydrolysis of glycerophosphate, however, increases up to pH 9·4, but at the same time inactivation of the enzyme is accelerated. It hydrolyses the phosphoric esters of the plasma. Small amounts of inorganic phosphate but not of glycerol retard the hydrolysis of glycerophosphate; in the presence of high concentrations of the alcohol it is capable of bringing about esterification of phosphate (Martland and Robison: *ibid.*, vol. 20, p. 847; 1926: vol. 21, p. 665; 1927).

H. B. Fell and Robison have investigated the phosphatase activity of embryonic avian femora, cultivated *in vitro* (*ibid.*, vol. 23, p. 767; 1929). They found that the tissue synthesised the enzyme during cultivation; the amount in the bone increased to a maximum and then declined, corresponding to the phases of histological differentiation followed by degeneration. The course of development was similar

to that occurring normally *in vivo*, but the degree of development attained was less. The enzyme is confined to bone and ossifying cartilage; it is absent from small-celled, non-hypertrophied cartilage. It presumably plays some part in calcification: it has been shown that it is capable of causing the deposition of calcium phosphate from calcium glycerophosphate in the complete absence of inorganic phosphate (for example, Robison, *ibid.*, vol. 20, p. 388; 1926).

T. H. Milroy examined the processes of fatigue and recovery in normal and diabetic muscle and found that fatigue was characterised by the entrance of water, the loss of some phosphate, depletion of the glycogen store, and increase in lactic acid, together with loss of the power of esterification of phosphate under the influence of sodium fluoride (*Quart. Jour. Exp. Physiol.*, vol. 17, p. 161; 1927). In recovery the reverse changes were observed; with muscle taken from a depancreatised cat, the recovery processes were much slower, especially the storage of glycogen and the ability to synthesise hexose phosphate.

D. Stiven has recently investigated in detail the part played by phosphoric esters in the formation of lactic acid from glycogen or starch, using a muscle extract: muscle from a cat perfused with Ringer's solution after killing instantaneously was extracted, after mincing, with cold sodium chloride and bicarbonate solution; the extract was obtained by pressing through muslin and concentrated by freezing out water; the pH was adjusted by adding phosphate and bicarbonate (*Biochem. Jour.*, vol. 22, pp. 867, 874, and 882; 1928: vol. 23, p. 583; 1929: vol. 24, pp. 169 and 172; 1930). Under anaerobic conditions, the extract produces lactic acid from glycogen, starch, or glucose, though at somewhat different rates. With glycogen as substrate, the changes in phosphoric esters were followed in detail and found to be of three types: in the first, there is no ester accumulation or change in phosphate until all the glycogen has been used up, when phosphate increases; in the second, no ester accumulates for the first 30–40 min. of incubation, but thereafter accumulation is rapid; in the third, ester accumulates at the commencement and is then broken down. The actual course depends in part on the concentration of glycogen and the extract used. In any event, there is no molar relationship between lactic acid production and phosphoric ester accumulation or breakdown.

Addition of hexose diphosphate under certain conditions inhibits lactic acid formation and increases the formation of phosphoric ester; at the same time the glycogen decreases more rapidly than when the addition is not made. Stiven has also found that a sterile cell-free muscle extract prepared from a cat or wild rabbit will convert glucose to lactic acid without the addition of any activator; the glycolysis occurred in the early stages of incubation and was certainly due to the muscle enzymes and not to any infection.

Although the rate and extent of lactic acid formation from glucose are usually greater than from glycogen, the ester accumulation is much greater in the case of the latter. Again, the rate of lactic acid production and ester accumulation is greater with glycogen than with soluble starch in the earlier stages of the reaction, although finally the lactic acid formation is the same with both. Irradiation of the muscle extract with ultra-violet rays from a quartz mercury vapour lamp for short periods increased the rate of lactic acid production from glycogen; at first ester accumulation increased, but later decreased, coincident with the maximum rate of formation of the acid; longer exposures destroyed the enzyme. These results differ in some respects from those obtained by previous observers, and further work will be necessary before the details of the chemical changes produced by muscle or muscle extracts upon carbohydrates are finally and completely elucidated.

The Psychology of Adolescence.

THE psychology of adolescence has not received from psychologists that attention which its popularity with novelists, poets, and painters would seem to merit. It is, therefore, a matter of interest that, at the Bristol meeting of the British Association, Section J (Psychology) devoted the whole of a morning's session to hearing and discussing four papers on this subject.

In his paper on "The Basis of Social Adjustment", Dr. R. G. Gordon maintained that the problems of adolescence were largely problems of adjustment to society, and that the success of such adjustment depended on the formation of a sentiment of a social self which should in large measure dominate the other sentiments in the personality. The organisation of this sentiment, he said, depended on certain emotional dispositions or instincts: suggestibility, passive sympathy, imitation, and the herd instinct—the last of these being of first importance. These, however, were not enough, for the mentally defective often exhibited them in no small degree and yet was almost totally ineducable: he showed no particular peculiarities in respect of the instinctive bases of social adjustment; he was, for example, no more suggestible than normal people. Nor was the tale completed by the sex instinct. "To describe social intercourse as a manifestation of sexuality", said Dr. Gordon, "is, to my mind, a mistake. What the sex instinct does is to give a tremendous impulse to extraversion: it directs the individual's interest away from himself." He made the interesting suggestion that differences in the strength of the herd instinct were largely responsible for differences between the introvert and the extravert. These emotional dispositions, he said, had to be controlled and organised, and the individual had to learn to discriminate between what met with social approval and what did not. This control, integration, and discrimination depended on the acquisition of knowledge, the organisation of beliefs, and the development of the power of making sound judgments. It was in these respects that the mentally defective was lacking. They were associated with the proper development of the cerebral cortex: so social adjustment had to be regarded as of gradual development and only coming to fruition with a full functional activity of the cortex.

Dr. Gordon made an interesting distinction between the control, integration, and discrimination implied in social adjustment and what is commonly called intelligence, and suggested that some intelligent people never developed the capacity for social adjustment, because they were lacking in the special cortical development necessary for the integration of their instincts and the formation of the social sentiments: they were aments in spite of their intelligence. Such people might compensate either by an intense integration of the ego-centric sentiment, as in the typical epileptic personality, or by failure to adjust to life, as in many psychasthenics and chronic hypochondriacs, who preferred illness to health, finding

that a convenient way of escape from social adaptation.

Prof. Olive Wheeler, in her paper on "Variations in the Emotional Development of Normal Adolescents", gave some account of the results of her own inquiries, in which she used the questionnaire method. The replies to her questions pointed to an increase of emotionality during the period of adolescence, which showed itself in three directions: first, an increased feeling of self, tending towards psychological independence and the finding of a vocation; second, a rise or intensification of sex emotions, tending towards the development of a hetero-sexual attitude and the finding of a mate; and third, the development of social, æsthetic, and religious emotions, tending towards the formulating of a point of view on society and on life in general. There were great variations in the time and rate of this emotional development, and equally great variations in the intensity of the new experiences; in some cases there appeared to be a great accession of energy along each of the three chief channels of experience and adjustment, an observation which supported Burt's hypothesis of a central emotional factor.

As regards emotional differences between the sexes, Prof. Wheeler thought that, apart from the earlier emotional maturity of the girl, the most striking difference between the sexes was to be found in a difference of emphasis on the active and passive groups of emotions: boys tended to be more aggressive; their misdemeanours were aggressive (pugnacity, acquisition), while those of girls were passive (lying, sex offences, and attempted suicides). This difference, it was suggested, might be partly responsible for the fact that highly intelligent girls and women found it more difficult to attain that eminence in professional, business, or cultural life justified by their intellectual ability: in boys there was a harmony between the egoistic and the sex emotions which resulted in activity, while in girls there was a perpetual liability to conflict between them, which tended to a passive resultant.

Concerning environmental influences, Dr. Wheeler expressed the opinion that emotional maturity was much more affected by training and circumstances, particularly by the home, than is any other phase of development. Many parents delayed the psychological weaning of their children, with serious consequences; they tended to keep their sons and daughters in emotional leading-strings and to allow them too little freedom of thought and action. The long preparation period necessary for entrance into the professions made difficult the harmonious development of some adolescents: biological maturity was attained before economic independence was reached. Hence the self-help movement, which largely arose through stress of economic circumstances and was beginning to be a feature of English (as of American and Scottish) university life, was psychologically sound: in their vacations, at any rate, students could get a taste of real work, responsibility, and economic independence. The difficulties were very much greater for the youth who was unemployed and sometimes found a mate before he found a vocation and had been trained by work to accept responsibilities and to consider the rights and needs of others.

The development of the young industrial worker of the continuation school was discussed by Miss M. Phillips in a paper entitled "The Adolescence of the Young Wage-earner". His social development, she said, was hampered by his limited environment. Repetitive work provided an even more restricted environment than did the school-room: it provided him with few opportunities of expressing his initiative. Most of these workers resigned themselves to the world as they saw it, and resorted to fantasy: so... sought opportunities for development in persor... relationships outside of the workshop: a few carri... the unadventurous, spiritless attitude of the worksh... into their personal relationships.

The fourth paper, by Miss A. H. M'Allister, ... "Adolescent Modes of Thinking", gave an account ... her own observations made with a method of studyi... adolescent thought, which seems very promising. Sh... compared some 400 stories written by girls of ... and women of 30 to be told to children, thinking th... the writers would in the selection and treatment ... their material reveal their own attitude of life; a... her expectations were fully realised, for there we... distinct differences between the stories of the youn... women and those of the older, which can only ... explained by their difference of outlook. Fairy stor... were more popular with the adolescents and w... treated somewhat differently: they depicted a beau... ful, busy, but secret world, a place of feasting a... dancing and all sorts of wild impossibilities; it w... an expression of the adolescent's growing interest in t... world, of her hopes, and realisation of her own inde... pendence: those of the older women were more sobe... by comparison. A curious feature of the adolescent... stories, one which raises a problem for the psychoanalyst, was the comparative absence of 'fathers'; 'mothers' were plentiful, but 'father' was seldom introduced, and then usually to explain his absence.

Anthropology and Archæology in the "Encyclopædia Britannica".

AS a survey of natural and applied science the "Encyclopædia Britannica" is a record of stupendous achievement by the human intellect in probing Nature's secrets and in the reduction of material conditions to subservience to man's needs. When we turn to the sciences which deal specifically with man himself and his past, we enter upon a field of discovery in which the results, if less spectacualr, offer no lesser appeal to the imagination, and redound no less to the credit of those to whose genius and patient piecing together of the evidence they have been due.

In those branches of science which deal with the origin and development of man and the growth of civilisation, there is one name which dominates all others, one man whose influence and example, explicit or merely implied, permeate the whole and determine the attitude of the investigator towards his material. That man is Darwin. In his article on the evolution of man, Sir Arthur Keith, in paying a tribute to Sir Edward Tylor, the greatest of the early anthropologists, emphasises the effect of his acceptance of the evolutionary theory of human descent as a working hypothesis. He goes on to demonstrate that Darwin's views on the descent of man have withstood all attack, remaining the only sound guiding principle in interpreting the facts.

An earlier generation, apt to facile generalisation, found in the Darwinian theory a ready key to the solution of all its difficulties. Since then as the facts have accumulated they have been seen to conflict with the crudities of premature theorising, and this has led to a popular misconception that the Darwinian position has been discredited. Far from this being the case, as Sir Arthur Keith shows, for example, in his review of the evidence of embryology on the descent

of man, the facts on a subtler interpretation only serve to confirm it. The tree of human descent still flourishes, but instead of a single stem, it has put forth many branches, each a specialised adaptation to its environment. We may no longer believe that men are descended from monkeys, but rather that in the line of descent the anthropoids are early forms which branched off, and have had to pay the penalty of too early specialisation.

It must not be concluded that there are no gaps in our theories, that no difficulties remain to be solved. There are still divergences of view. For these we refer the reader to Sir Arthur Keith's article, in which he pilots a way through the evidence from the anthropoids, *Pithecanthropus erectus*, Piltdown, Neanderthal, Rhodesian man, and the rest. Unfortunately, Peking man came too late to fit into Sir Arthur Keith's chain of evidence. A mere reference to the articles on "Heredity" and "Eugenics" for the place of Darwin in other fields must suffice as we pass to the study of man in its wider aspects. Dr. Marett in his article on "Anthropology" largely attributes the foundation of anthropology in its modern sense to Darwin's revolution in the study of biology. Man and his customs and institutions, it is true, have been a subject of curiosity from time immemorial. Herodotus is the father of anthropology just as much as of history. The study of archæology goes back at least to the Renaissance, as is pointed out in the article "Archæology" by Dr. Hall. But when Darwin published his "Origin of Species", as Dr. Marett says, "the time was at length ripe for a world-wide, age-long survey of the human record". Hence Dr. Marett has taken human survival as the prime object of anthropological study. It was the Darwinian theory of the struggle for existence and the survival of the fittest which provided method, a unity of aim, and a consequent strictness of procedure in dealing with the enormous range and diversity of the material for such a survey, and it is in the light of their survival value that Dr. Marett deals with the study of race and culture, language, social institutions, religion, and morals. It may be noted that Dr. Marett eschews the practically convenient but theoretically unjustifiable arbitrary divorce between prehistoric man, the modern savage, and civilised man. All are equally subject to the same biological canon.

In accordance with the scheme of arrangement of the "Encyclopædia", Dr. Marett has dealt with general principles only. Subsidiary articles cover the question of racial characters, racial distribution, social institutions, and culture under continents or countries as circumstances dictate. Others deal with special subjects of inquiry such as exogamy, kinship, marriage, totemism, and the like. Dr. Harrison's article on "Material Culture" is of special interest at the moment in its bearing upon the question as to how far development in material culture is to be regarded as due to independent invention or to a diffusion from a given centre—a subject which he developed further in his recent address to the anthropological section of the British Association at Bristol.

Those who are prone to ask what is the practical outcome of research and to demand some ultimate utility from academic studies may refer to Prof. Seligman's "Anthropology, Applied", in which he deals with the bearing of anthropological studies on the problems of the administrator in dealing with primitive races in our dependencies, drawing instances from his experience in the field.

When we turn to the treatment of archæological studies in the "Encyclopædia", it is inevitable that attention should be directed in the first instance to the general article by the late Dr. H. R. Hall, whose untimely death we all deplore. In accordance with the general scheme for strengthening the appeal of the scientific articles to a wider public, Dr. Hall has opened with a brief history and methodology of his subject. Two points are immediately presented to the reader with no little force. First is the astonishingly rapid increase in our knowledge in recent years, particularly since the War; and second, the need now felt for technical training in the practical archæologist and the wide range of knowledge which that training must cover, not merely within the four corners of the subject, but also in a wide variety of subjects which impinge upon work in the museums, and still more in the field, and involve problems ranging from practical chemistry to engineering. Dr. Hall is in accord with the spirit of the "Encyclopædia", though he may, perhaps, have felt a little ill at ease in seeking a practical end for archæological studies which he justifies, were justification needed, as one of the 'things of the spirit'.

The final word on method rests with Mr. O. G. S. Crawford, who from the fund of his practical experience deals with archæological discovery from the aeroplane.

The general survey of the stone ages by Mr. M. C. Burkitt, the bronze age by Mr. H. J. E. Peake, and the iron age by Mr. Reginald Smith are synthetic rather than analytic. Even more than in their detail, their general trend marks the advance in archæological studies of recent years. It is of no little significance that the treatment of the larger problems of archæology tends to expand in range until, in the earlier phases at least, it is little short of world-wide. This would have been even more evident had publication been delayed by a little to include discussion of recent evidence from China, India, and Africa which holds out possibilities of world-wide correlations in prehistoric times based on climatological and meteorological argument. As it is, Prof. Seligman could barely touch on Mr. L. S. B. Leakey's discoveries in East Africa.

It is when reference is made to the departmental articles, mostly under geographical headings, that the increase in the sum of detailed knowledge becomes impressive. In this connexion Mesopotamia with its record of recent excavation must hold first place; but Egypt with Badari and the Faiyum, India with Mohenjo-daro and Harappa, China, and Palestine each contribute no less significantly if less sensationally to the archæological picture of the growth of civilisation in prehistoric times which gradually is being pieced together. By no means less important is the eastern European area, of which the prehistoric archæology is ably surveyed by Prof. Gordon Childe. Less attractive, perhaps, to any but the expert because of its difficulties, of which not the least is the language in which most of the original records of research are published, it assumes its proper perspective in Prof. Childe's hands in linking up the cultures of Central Europe, the Danubian area, and the eastern Mediterranean.

It would be impossible even to glance in passing at the many fascinating problems which now engage the attention of the archæologist and are here recorded—the Hittite empire and its ramifications, which the archæological and philological evidence carries, on one side to India, and, on the other, to the peoples of the Mediterranean; the cultures of the south-western United States, in which an archæological method and framework develop as evidence accumulates; and the great pre-Columbian civilisations of Central and South America. As a whole, archæology in the "Encyclopædia" is a record of great achievement reared upon a sound basis of carefully observed and recorded fact.

Fog and Mortality in the Meuse Valley.

FOR three days last week, Dec. 3-5, a heavy fog occurred in part of the Meuse valley, in the industrial area between Huy and Seraing, south-west of Liège, as a result of which sixty-four persons and a number of cattle are dead. An official medical commission which investigated the circumstances has reported that the deaths were due to fog alone; the victims were persons who, by reason of old age or ill health, were in a low state of health.

The Ministry of Health has been in communication with the health authorities in Belgium and is informed that the recent deaths in the province of Liège are not due to any communicable disease; the occurrence is clearly a matter of local conditions, but it may be some days before the cause is fully and authoritatively ascertained.

The fog formed part of a very extensive area of fog associated with an anticyclone that extended westwards from eastern Europe. Precise information as to the density of the fog in the afflicted area is wanting, but the accounts do not suggest that it was any greater than that of the worst London fogs, in which visibility is occasionally reduced to less than two yards. A number of upper air soundings made in Great Britain and on the Continent at this time showed that above a superficial layer of low temperature there was a rapid rise of temperature with height, the air above a height of 5000 ft. being about as warm as on an average day in August, when the annual maximum occurs at these levels. This state of affairs is, of course, very favourable for maintaining a fog, because of the extreme vertical stability that results. The atmospheric eddies that under ordinary conditions cause a constant interchange of air at different heights cannot be present, for any cold air from near the ground if raised to a higher level would have its deficit of temperature increased by dynamical cooling, and its increasing excess of density would introduce a powerful restoring force.

Fog, however, does not originate because of such conditions; it is generally caused by the cooling of the surface layers under a clear sky in the absence of strong wind. The evidence points to this having been the mode of origin of the fog area in Europe as a whole on this occasion. Apart from the fact that the general level of temperature was much higher than is usual in a December fog and that there was an unusually large 'inversion of temperature', the meteorological conditions appear to have been characteristic of the type of weather. If any poisonous fumes or solid particles are present in the surface layers of the atmosphere, they will remain there for so long as the state of exceptional stability lasts. The presence of some such fumes as the cause of the deaths near Liège seems a more reasonable supposition than the alternative one of suffocation through sheer density of fog, because the ordinary particles of fog, whether these are drops of water or minute particles of solid matter, or, as often happens in industrial areas, a mixture of the two, occupy only a minute proportion, by volume, of the atmosphere, and can scarcely be supposed to prevent a due amount of oxygen from being inhaled even by people with impaired lungs.

If these conclusions are correct, the cause of recent deaths in the Meuse valley will be found only by more thorough investigation into the manner of the victims' death. The possibility must also be taken into account that recent industrial developments may have resulted in the liberation of poisonous products on a scale that will become destructive whenever scavenging of the air by turbulence is reduced by exceptional temperature conditions aloft.

University and Educational Intelligence.

CAMBRIDGE.—The Council of the Senate has appointed the following Committee for the James Clerk Maxwell centenary celebration: The Vice Chancellor; Sir J. J. Thomson; Mr. W. Spens, Master of Corpus Christi College; Sir Joseph Larmor, Sir Ernest Rutherford, Dr. C. D. Broad, Prof. H. F Newall, Sir Arthur Eddington, Prof. C. T. R. Wilson, Prof. F. J. M. Stratton, Dr. J. Chadwick, Dr. J. D Cockcroft, Sir James Jeans.

The Managers of the Balfour Fund, with the approval of the Faculty Board of Biology "A", have made a grant of £30 from the Balfour Fund to Miss P. M. Jenkin, of Newnham College, for research on "The Biology of the Smaller African Lakes".

H. G. Wager, of Emmanuel College, has been appointed to the Frank Smart University Studentship in botany.

SCHOLARSHIPS, each of the annual value of £300 plus an allowance for apparatus and other expenses, are being offered by the Grocers Company, the object being the encouragement of original research in sanitary science. Forms of application and particulars can be had from the Clerk to the Grocers Company, Grocers Hall, E.C.2.

A SERIES of twelve Swiney Lectures entitled "The Life of the Past" will be given by Dr. T. M Finlay in the lecture theatre of the Imperial College of Science (Royal College of Science, Old Building), at 5.30 on Mondays, Wednesdays, and Fridays, on Dec. 8-19 and on Jan. 5-16. Admission is free.

UNIVERSITY entrance tests and initial degrees form the subject of a report recently adopted by the council of the Association of University Teachers and published in the October number of the Association's *Universities Review*. The report surveys the existing arrangements for matriculating students in the various universities and finds them unsatisfactory, in that, on one hand, they fail to exact from every entrant valid evidence of preparedness for university work, and on the other, they exert an unhealthy influence on schools in the direction of premature specialisation. It recommends the prescription of a minimum entrance age of about eighteen years; an efficient test in the use of English; a test, to be passed shortly before entry, in four subjects, not involving such a high degree of specialisation as the higher school certificate examinations; and a certificate by the candidate's school authorities as to his powers and interests and general fitness for university work. As regards the test in English, the report expresses approval of the general principles of recommendations embodied in an article by Miss Maitland Smith which appears in the same number of the *Review* under the title "Entrance Examination in the Understanding and Use of English". Although the suggested improvement of the efficiency of entrance tests might be expected to rehabilitate to some extent the depreciated pass degrees of the new universities, the report urges these bodies to retrieve the mistake they made in reserving 'honours' exclusively for success in highly specialised courses, with the result that every ambitious student, whether he really wishes and is fitted to press on to the frontier of knowledge in one particular direction or not, is driven to do so.

Historic Natural Events.

Dec. 14, 763. Cold Winter in Western Europe.—The winter of 763–4, the first concerning which details are extant, appears to have been very cold in western Europe. Winter began early in October, but the greatest cold continued from Dec. 14 until Mar. 16. It extended over the whole of Europe, from England to the Black Sea. The Bosphorus and neighbouring parts of the Black Sea were frozen; in several countries the snow was 30 ft. deep in places, and in Gaul the olives and figs died, the corn froze in the soil, and in 764 a terrible famine desolated a vast region and cost a multitude of lives. The Danube and other rivers were frozen, as was the sea for a long distance from the land. Holinshed records: "There fell such a marvellous great snow, and therewith so extreme a frost, as the like had not been heard of, continuing from the beginning of the winter almost till the midst of spring, with the rigour whereof trees and fruits withered away, and not only feathered fowls, but also beasts on the land and fishes in the sea died in great numbers." It is not mentioned in the Anglo-Saxon Chronicle, but an entry in 761 records: "This year was the severe winter", and there may be some confusion of dates.

Dec. 16, 1857. Neapolitan Earthquake.—This earthquake is notable as the first in which an attempt was made to estimate the depth of the focus. By numerous measurements of the inclination of fissures in buildings, etc., Mallet found that the depth was about 6½ miles.

Dec. 16, 1877. High Pressure over Siberia.—At Semipalatinsk in Siberia the barometer at 9 P.M. read 84·5 mm., equal to 1046 mb. or 30·886 in. The height of the station is not known exactly, but is estimated as 590 feet, and on this basis the pressure corrected to sea level is 1075 mb. (31·75 in.). This is the highest known pressure at sea level. At 7 A.M. on Dec. 17, a reading of 787·4 mm. (1050 mb. or 31·00 in.) was recorded at Barnaoul, a few degrees east of Semipalatinsk. The height of this station is 480 feet, and the pressure reduced to sea level, 1073 mb. (31·69 in.).

Dec. 16, 1920. Great Chinese Earthquake.—One of the greatest earthquakes known to us occurred in the provinces of Kansu and Shensi in north-west China. The area disturbed must have been more than three million square miles, the largest yet known. The number of persons killed, chiefly residents in caves in the river-banks, was estimated at 180,000.

Dec. 16-21, 1925. Tropical Cyclone in Pacific.—A violent cyclone visited the Union, Samoa, and Cook Islands. A cyclone wave swept over Atafu in the Union Islands, and great damage was done by the wind at Rarotonga (Cook Islands).

Dec. 17, 1664. Comet.—Under this date Pepys wrote: "Mighty talk there is of this Comet that is seen a' nights, and the King and Queene did sit up last night to see it, and did, it seems."

Dec. 18, 1896. Ball Lightning in Devon.—During a thunderstorm at Brixham, Devon, a globe of light appeared in a field, travelling from west to east, tearing up the ground. It reached a small house, broke a hole in the closed door, knocked a hole in the wall, and continued along a rope walk, where it killed one man and gravely injured another.

Dec. 19-22, 1929. Snowstorm in Texas.—Snow is rare in central Texas, but in this storm the depth of snow exceeded two feet in places and traffic was disorganised; at Hillsboro 26 inches fell in less than 48 hours. Two inches of snow fell even on the coast, where such a phenomenon is almost unprecedented. The pressure distribution on Dec. 18 showed a deep depression over the Gulf States, bringing in large quantities of moist air, while a cold wave was advancing from an intense anticyclone over Montana, associated with temperatures below 0° F. The snowstorm accompanied the progress of this cold wave, first southwards and then eastwards to the coast.

Dec. 20, 1564. Severe Winter in Europe.—The winter of 1564–65 was very severe over the whole of Europe. The cold began about Dec. 20, and Holinshed states that on New Year's Eve "people went over and alongst the Thames on the ise, from London Bridge to Westminster. On Jan. 3 at night, it began to thaw, and on the fifth there was no ise to be seene betweene London Bridge and Lambeth, which sudden thaw caused great floods, and high waters, that bare downe bridges and houses, and drowned manie people in England, especially in Yorkshire. Owes Bridge was borne awaie, with others." The Zuider Zee and all the great waters of western Europe were frozen; on the Continent the cold continued until Mar. 24.

Societies and Academies.

LONDON.

Physical Society, Oct. 17.—J. P. Andrews: (1) A simple approximate theory of the pressure between two bodies in contact. The approximation makes use of two principles: (a) The displacement at the centre of the circle of contact is twice that at its edge, and (b) for the purpose of calculating the stresses we may replace the two bodies by a single sphere of which the circle of contact is a diametral section, and write the strain at any point as the ratio of the displacement of that point to the length of the line drawn from the point to the sphere in the direction of displacement. When the elastic modulus by which this is multiplied is taken as that appropriate to a rod with sides fixed, the agreement with accurate theory is close. Principle (a) remains nearly true for elliptical areas of contact.—(2) Experiments on impact. For soft metallic bodies and impact of equal spheres, for small velocity of approach v, duration of contact varies inversely as $v^{1/5}$, while the coefficients of restitution e are unity for all speeds below a value characteristic of each material. Duration of contact has no effect upon the size of the permanent deformations. For variation of duration of contact t with mass of sphere at high speeds of approach, t varies as the square root of the mass, as theory predicts.—(3) Observations on percussion figures. Steel ball on glass blocks. Diameter of innermost circular or part-circular crack remains constant for one specimen of glass, and is independent of the maximum pressure exerted by the ball on the glass; diameter of outermost circular or part-circular crack varies with the maximum pressure in a manner which suggests that the crack tends to keep to the outer edge of the area of contact. No crack is formed until the pressure exceeds a value characteristic of the glass.

Geological Society, Nov. 5.—H. Williams and O. M. B. Bulman: The geology of the Dolwyddelan Syncline (North Wales). The syncline lies east of Snowdon and south of Capel Curig, extending along the Lledr Valley westwards from the village of Dolwyddelan. The rock-sequence is closely comparable with that determined by the senior author on Snowdon, and the pyroclastic rocks of Dolwyddelan are, in effect, the attenuated and ragged margin of the great Snowdonian volcanic mass. The central portion of the northern limb of the syncline has been

overturned, accomplished probably by a kind of 'underdrive', much of which took place prior to and during the impression of cleavage, but the final stages of which seem to have been part of a general post-cleavage movement. Large bodies of fresh augite-dolerite, well developed along the northern limb of the syncline, testify to the post-cleavage intrusion of basic magmas.—**L. R. Wager**: Jointing in the Great Scar Limestone of Craven, and its relation to the tectonics of the area. The Great Scar Limestone of Craven is traversed by two sets of nearly vertical joints, which are usually at right angles one to the other. Some 4 miles north-west of Grassington-in-Wharfedale, the lead-veins run parallel to one set of the joints, and were in fact deposited in widened joints. The joints and mineral veins are constant in direction over a considerable area; but as the North Craven Fault is approached, their direction is modified. These preliminary observations showed that the formation of the joints preceded the mineralisation, which is probably of Pre-Permian age, and suggested that the jointing and the Craven Faults may be related, since the modification in the direction of the joints is localised near the faults. In order to test this hypothesis, the joints have been examined over a wide area.

CAMBRIDGE.

Philosophical Society, Oct. 27.—**Sir A. S. Eddington**: On the masses of the electron, the proton, and the universe. The opposite cyclic behaviour of protons and electrons, expressed by symbols of the type $e^{i\theta}$, $e^{-i\theta}$, would involve reciprocal behaviour in the corresponding real transformations e^{θ}, $e^{-\theta}$. A theory of the masses is proposed, according to which the representation of a microscopic system with 136 cyclic momenta in a microscopic space-time with only 10 cyclic momenta increases the natural mass of the proton in the ratio $136:\sqrt{10}$ and diminishes that of the electron in an equal ratio. The $\sqrt{10}$ is due to the 10 momenta occurring in a quadratic Hamiltonian, whereas the 136 occur in a linear Hamiltonian. This gives $M/m = 1849 \cdot 6$. A certain amount of check is provided by (1) the 'packing fraction', which corresponds to the increase from 136 to 137 cyclic momenta when the charges are in a perfectly rigid nucleus; (2) the 'original' mass of a charge being $\sqrt{Mm}$, the square of the ratio of electrical to gravitational energy ($5 \cdot 2 \times 10^{78}$) comes to be of nearly the same order as the number of particles in the universe ($1 \cdot 4 \times 10^{79}$) determined from the recession of the spiral nebulæ.

PARIS.

Academy of Sciences, Nov. 10.—**Emile Borel**: The extension of the properties of irreducible polynomials to integral functions.—**Georges Perrier**: The section of geodesy of the International Geodetic and Geophysical Union at the general meeting at Stockholm, Aug. 11-23, 1930.—**Georges Claude**: The utilisation of the thermal energy of the sea. Additional results obtained in the experiment at Matanzas.—**B. Berloty**: The localisation of the epicentres of earthquakes. From theoretical considerations, the parallel of articulation and deformation of a flattened ellipsoid such as the earth, is 35° 15′ 52″. Data extracted from nine years of the International Seismological Summary are discussed and the conclusion drawn that the parallel of deformation is only 16″ from that indicated by theory.—**Paul Delens**: Functions with complex variable and geometrical representations.—**Marcel Vasseur**: The deformation of congruences of normals.—**Georges Bouligand**: Applications of the idea of the contingent.—**Georges Durand**: A type of points of the envelopes of spheres.—**Nikola Obrechkoff**: The exponential summation of Borel.—**M. Lavrentieff**: A problem of maximum in conformal representation.—**F. E. Myard**: A generalisation of Cardan's joint.—**R. Mazet**: The stability of certain isolated vortices.—**Lyot**: The solar corona studied apart from eclipses. This work was carried out at the Observatory at the Pic du Midi, on account of the purity of the atmosphere at this elevation. The sun's image was formed on a metallic screen extending 30″ over the sun border. Protected by this screen, observations could be made directly with the eyepiece. The prominences were visible without the assistance of the spectroscope and showed the same pink colour seen during eclipses. The polarisation of the corona was examined under these conditions. The polarisation found was not instrumental or of atmospheric origin: the results are given graphically.—**Ernest Esclangon**: Remarks on the preceding communication. The author considers that this marks a new stage in the study of the solar corona.—**H. Deslandres**: Remarks on M. Lyot's communication.—**Jean Becquerel, W. J. de Haas**, and **H. A. Kramers**: The law of paramagnetic rotation in xenotime and its experimental verification. Comparison of the experimental results obtained at absolute temperatures of 4·22° and 1·38° with those calculated from the modified formula given in an earlier paper.—**J. Cichocki**: The diffusion of the ions of salts in aluminium. The phenomena described by Peczalski for copper and iron are reproduced in the case of aluminium, except that no negative thermionic emission has been observed for the last-named metal.—**M.** and **Mme. Clément Duval**: The isomerism of radicals.—**Raymond Delaby** and **Mlle. Jeanne Hiron**: The generalisation of Skraup's reaction applied to α-alkylglycerols. A description of the preparation and properties of α-ethylquinoline, α-propylquinoline, and α-butylquinoline.—**Maurice Marie Janot**: Sclareol and its derivatives. The formula deduced from the analyses given is $C_{17}H_{30}O_2$. The physical properties and chemical reactions are given.—**Fernand Blanchet**: Some new or little known facts concerning the geology of the southern Briançonnais (Massif d'Escreins Hautes-Alpes).—**A. Mailhe** and **Renaudie**: The transformation of propylene into liquid hydrocarbons. A study of the effect of silica gel at 650° C. on propylene.—**René Truchet**: A method of preparation of substituted acetylene hydrocarbons. The methyl esters of benzenesulphonic acid and of p-toluenesulphonic acid can replace methyl sulphate as a methylating agent in many cases. By the reaction

$$R.C:C.Na + C_6H_5SO_3R' = R.C:C.R' + C_6H_5SO_3Na$$

the author has prepared nonine, decine, and undecine.—**C. P. Nicolesco**: Discovery of the Senonian on the banks of the Seine between Gonfreville-l'Orcher and Bacqueville, to the east of Tancarville.—**André Ike Duninowski**: A new method for the optical estimation of atmospheric ozone. The usual method of measuring atmospheric ozone is based on the absorption in the ultra-violet, but Cabannes and Dufay, working on observations made at the Mount Wilson Observatory, have deduced the proportion of ozone from the atmospheric absorption in the visible region of the spectrum. The author has developed the latter method, using a linear thermoelement placed in a vacuum. The method has proved sufficiently sensitive to give accurate daily means, the accuracy being sufficient to give the thickness of the ozone to 0·2 mm. (at atmospheric pressure).—**Pierre Lesage**: The growth of *Lepidum sativum* cultivated at different latitudes in 1930.—**Robert Lami**: The liberation of iodine from the *ioduques* of *Bonnemaisonia asparagoides* under the action of the ultra-violet rays.—**Joyet-Lavergne**: The ratios between the intracellul

rH and the cytoplasmic sexualisation of the spores of horsetails.—**St. Ionesco**: The presence of tanoids in flowers.—**Raymond-Hamet**: The physiological action of aminomethyl-3 . 4-dioxyphenol carbinol.—**Louis Rapkine**: The chemical processes in the course of cell division.—**Lespes, Regnier, and Rungs**: Contribution to the study of the phases of the locust, *Schistocerca gregaria*.—**Mlle. Simone Mouchet**: The comparative morphology of the deferent canals of *Pagurus*.—**Etienne Rabaud**: The standing of *Argiope bruennichi* on its cobweb.—**L. Lutz**: The soluble ferments secreted by the Hymenomycetes fungi. The quinones and the antoxygen function.—**M. Javillier** and **Mlle. L. Emerique**: Biochemical researches on rubrene. Rubrene exerts no toxic action on rats, and does not replace vitamin A.—**Constantino Gorini**: Acidoproteolytic bacteria in pasteurised milk.—**Maurice Piettre** and **Pierre Villedieu**: The attenuation of the anthrax bacterium as a function of the nutrition.—**E. Brumpt**: The transmission of Marseilles exanthematic fever by the dog tic, *Rhipicephalus sanguineus*.—**J. Verge**: The second intradermomalleination in the glandered horse.

CATALOGUES.

A Rough List of Selected Works on Natural History, including Periodicals and Publications of the Learned Societies. Third Portion. (New Series, No. 23.) Pp. 109-152 (London: Wheldon and Wesley, Ltd.)

A Selection of Valuable Books (Catalogue No. 31.) Pp. 100. (London: William H Robinson Ltd.)

A Catalogue of Books on British and Foreign Birds Pp. 16. (London: Francis Edwards, Ltd.)

Choice Books: XVI-XVII Century, First Editions, Modern Presses. (No. 454.) Pp. 42. A Catalogue of Works on Political Economy. (No. 455.) Pp. 64. (Cambridge: Bowes and Bowes.)

Diary of Societies.

FRIDAY, DECEMBER 12.

ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botany Department Lecture Room, Imperial College of Science and Technology), at 2.30.—The Purification of Waste Waters from Beet-Sugar Factories:—D. W. Cutler: Microbiological Aspects.—E. H. Richards: Biochemical Aspects.

DIESEL ENGINE USERS' ASSOCIATION (at Caxton Hall) at 3.30.—Major W. Gregson: Waste Heat Recovery from Internal Combustion Engines, with particular reference to Marine Oil Engines.

ILLUMINATING ENGINEERING SOCIETY (in Lecture Theatre of Holophane, Ltd., Elverton Street), at 4.30. Dr. S. English: Glasses for Use with Invisible (Ultra-violet and Infra-red) Rays.

ROYAL SOCIETY OF ARTS (Indian Meeting), at 4.30.—A. Wigglesworth: India's Commercial Fibres.

ROYAL ASTRONOMICAL SOCIETY, at 5.—E. A. Kreiken: (a) On the Relation of Colour and Spectral Type in the Different Galactic Latitudes; (b) On the Axial Rotation of the Stars; (c) Some further Remarks on the Rotation of the Stars.—Prof. H. N. Russell and R. S. Dugan: Apsidal Motion in Y Cygni and other Stars.

ROYAL SOCIETY OF MEDICINE (Ophthalmology Section) (at Central London Ophthalmic Hospital), at 5.

ROYAL SOCIETY OF MEDICINE (Clinical Section), at 5.30.

MALACOLOGICAL SOCIETY (at Linnean Society), at 6. Dr. B. Prashad: Further Notes on Indian *Ampullariidae*.—L. G. Hertlein: Changes of Nomenclature of some Recent and Fossil *Pectinidae*.—Dr. F. F. Laidlaw: On a suggested New Sub-Family, *Dyakiinae*, and a New Species.—Sir Joseph C. Verco and B. C. Cotton: The Spermatophore of *Sepioteuthis australis* Quoy & Gaimard.—R. Winckworth: Notes on Nomenclature. No. VII. *Helicella*.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—V. E. Pullin: X-Rays in Engineering Practice.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle-upon-Tyne), at 6.—W. J. Rees: Refractories for Boiler Furnaces.

INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section), at 6.15.—W. D. Oliphant: Laboratory Method as met with in Wireless Technique.

SOCIETY OF DYERS AND COLOURISTS (Manchester Section) (at 36 George Street, Manchester), at 7.—J. M. Preston: Theories of Lustre.—W. F. A. Ermen: Notes on the Iodine Mercerisation Test.

OIL AND COLOUR CHEMISTS' ASSOCIATION (Manchester Section) (at Royal Institution, Liverpool), at 7.—A. W. C. Harrison: The Incorporation of Dry Pigments into the Medium.

INSTITUTION OF STRUCTURAL ENGINEERS (at Chamber of Commerce, Birmingham), at 7.—A. C. Ansell and others: Discussion on Some Problems in the Design of Roof Truss Members.

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (jointly with South Wales Section of Institute of Chemistry) (at Thomas' Café, Swansea), at 7.30.—Dr. P. M. Davidson: The Structure of Molecules (Lecture).

JUNIOR INSTITUTION OF ENGINEERS (at Royal Society of Arts), at 7.30.—Sir Henry George Lyons: Technical Museums and their Value to Engineers (Presidential Address).

INSTITUTE OF FUEL (East Midlands Section) (at Derby Technical College), at 7.30.—T. F. Hurley: Some Factors influencing the Design of a Combustion Chamber for Pulverised Fuel.

KEIGHLEY ASSOCIATION OF ENGINEERS (at Queen's Hotel, Keighley), at 7.30.—A. Brier: Electrical Driving of Textile Machinery.

INSTITUTE OF METALS (Sheffield Section) (in Non-Ferrous Section of Applied Science Department, University, Sheffield), at 7.30.—R. H. D. Barklie and A. E. Nicol: Studies in the Electrodeposition of Silver. Throwing Power. The Behaviour of Silver Anodes, with special reference to Blackening and its Prevention.

INSTITUTION OF STRUCTURAL ENGINEERS (at Merchant Venturers' Technical College, Bristol), at 7.30.—E. S. Andrews: A Comparative Study of Retaining Walls.

SATURDAY, DECEMBER 13.

BRITISH PSYCHOLOGICAL SOCIETY (Annual General Meeting) (at University College), at 2.30.—Prof. Heidbreder: Thinking as an Instinct. —Dr. Stephenson: Application of the Theory of Two Factors to Non-verbal Tests.—Dr. Fortes: Perceptual Tests of 'G'.—Mr. Drake: Demonstration of some new Tests of Musical Ability.

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (at Newcastle-upon-Tyne), at 2.30. W. H. Connell: Some Recent Improvements in Surveying Instruments.—*Papers open for further discussion*:—Machine Mining in Faulted Ground, A. L. Ford; A Record of the Upper Carboniferous Non-Marine Lamellibranchs of Northumberland and Durham, and a Record of their Sequence, Dr. W. Hopkins.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3. Sir E. Denison Ross: Persia and the Persians (2): Art and Literature.

MONDAY, DECEMBER 15.

INSTITUTION OF MECHANICAL ENGINEERS (Graduates' Section, London) (jointly with Students' Sections of Institution of Civil Engineers and Institution of Electrical Engineers), at 6.45.—W. H. Evans: Industrial Psychology.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Eastern Centre) (at Armstrong College, Newcastle-upon-Tyne), at 7. Informal Discussion on Heating in the Home.

INSTITUTE OF FUEL (North-Western Section) (jointly with Institution of Electrical Engineers, Institution of Mechanical Engineers, and Association of Engineers) (at Engineers' Club, Manchester), at 7.—Major E. Ivor David: Private Generation of Electricity *versus* the Grid.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Group-Capt. the Hon. R. A. Cochrane: An Air Reconnaissance of the Hadhramaut.

TUESDAY, DECEMBER 16.

ROYAL SOCIETY OF MEDICINE, at 5.30.—General Meeting.

INSTITUTION OF CIVIL ENGINEERS, at 6.

INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section), at 6.15.—E. J. Loveridge and others: Informal Discussion on Commutator *versus* Slip-Ring Motors.

INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Centre) (at North British Station Hotel, Edinburgh), at 7.—G. Henderson: Modern Developments of the Metal cylinder Mercury-Arc Rectifier.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—L. V. Chilton: The Efficiency of the Safelights for Darkroom Use.—Dr. S. O. Rawling and Dr. G. B. Harrison: A Simplified Method of Measurement of pH by means of a Triode Valve and Glass Electrode.

SOCIETY OF CHEMICAL INDUSTRY (Newcastle-upon-Tyne Section) (jointly with Coke Oven Managers' Association, Northern Section) (at Armstrong College, Newcastle-upon-Tyne), at 7.30.—Dr. E. F. Armstrong: Coal as a Raw Material.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Tees-side Branch) (at Cleveland Scientific and Technical Institution), at 7.30.—J. Lang: Metallography of some Engineering Materials.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—Extraordinary General Meeting.—At 8.30.—A. Goodwin: The Stone Age in South Africa.

INSTITUTION OF ELECTRICAL ENGINEERS (East Midland Sub-Centre).—Dr. J. J. Rudra and Prof. Miles Walker: The Theory and Performance of Phase Advancers.

WEDNESDAY, DECEMBER 17.

SOCIETY OF GLASS TECHNOLOGY (in Chemistry Theatre, University College), at 2.—Discussion on The Flow of Glass in Tank Furnaces:—B. P. Dudding: Preliminary Statement.—E. A. Coad-Pryor, A. L. Marden, and J. B. Murgatroyd: Reports on the Results of Some Experiments made at the Works of United Glass Bottle Manufacturers, Ltd., Osram G.E.C. Glass Works, and Rockware Glass Syndicate, Ltd.

ROYAL METEOROLOGICAL SOCIETY, at 5.—Dr. J. Glasspoole: Heavy Falls of Rain in Short Periods (two hours or less).—W. D. Flower: An Analysis of the Cold Front over Egypt on March 7th, 1929.—M. T. Spence: The Factors Affecting Visibility at Valencia Observatory.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Dr. Harold Jeffreys: The Mechanics of Mountains.

NEWCOMEN SOCIETY FOR THE STUDY OF THE HISTORY OF ENGINEERING AND TECHNOLOGY (at 17 Fleet Street), at 5.30.—A. Titley: Cornish Mining: Notes from the Account Books of Richard Trevithick, Senior.

ROYAL MICROSCOPICAL SOCIETY (at B.M.A. House, Tavistock Square), at 5.30.—S. C. Akehurst: Observations on Pond Life, with Special Reference to the possible Causation of Swarming of Phytoplankton.—J. M. Preston: A New Top Light Illuminator.

INSTITUTION OF LOCOMOTIVE ENGINEERS (London Section) (at 296 Vauxhall Bridge Road), at 6.—H. I. Andrews: Possibilities of Condensing on Locomotives.

INSTITUTION OF AUTOMOBILE ENGINEERS (Wolverhampton Centre) (at Engineering and Scientific Club, Wolverhampton), at 7.30.—H. C. Armitage: Machine Tools from the Manufacturing Users' Point of View.

SOCIETY OF CHEMICAL INDUSTRY (Newcastle Section) (in Chemistry Theatre, Armstrong College, Newcastle-upon-Tyne), at 7.30.—Dr. E. F. Armstrong: Coal as a Raw Material.

INSTITUTION OF ELECTRICAL ENGINEERS (Sheffield Sub-Centre) (at Royal Victoria Hotel, Sheffield), at 7.30.

THURSDAY, DECEMBER 18.

INSTITUTION OF MINING AND METALLURGY (at Geological Society), at 5.30.—Prof. J. W. Gregory: The Copper Shale (Kupferschiefer) of Mansfeld.—G. Trestrail: (*a*) The Witherite Deposit of the Settlingstone Mines, Northumberland; (*b*) A Device for Controlling Mine Dams.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—Dr. J. J. Rudra and Prof. Miles Walker: The Theory and Performance of Phase Advancers.

INSTITUTION OF ELECTRICAL ENGINEERS (Tees-side Sub-Centre) (at Cleveland Technical Institute, Middlesbrough), at 7.—S. W. Melsom, A. N. Arman, and W. Bibby: Surge Investigations on Overhead Line and Cable Systems.

INSTITUTE OF RUBBER INDUSTRY (at Manchester Ltd., Manchester), at 7.—J. H. Carrington: The Use of Concentrated Latex in the Rubber Industry.

CHEMICAL SOCIETY, at 8.—R. Child and Prof. F. L. Pyman: 1-ω-halogenoalkylisoquinolines and their Derivatives.—E. Hope, Prof. F. L. Pyman, F. G. P. Remfry, and R. Robinson: A Synthesis of Hydrastine. Part I.

FRIDAY, DECEMBER 19.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Informal Meeting) (in Mining Institute, Newcastle-upon-Tyne), at 7.15.—E. L. Champness and others: Are we justified in using Steel and other Materials of Foreign Manufacture in the British Engineering Industries?

ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics and Comparative Medicine Sections), at 8.30.—Major A. A. Pryer, Dr. R. W. A. Salmond, Lieut.-Col. E. Middleton Perry, Dr. J. B. King, and others: Discussion on A Comparison of Radiological Problems in Man and Animals.

PUBLIC LECTURES.

FRIDAY, DECEMBER 12.

INSTITUTE OF INDUSTRIAL ADMINISTRATION (at Institute of Hygiene, 28 Portland Place), at 5.30. A. S. Comyns Carr: Education for Management, to be followed by a discussion.

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Technical College, Cardiff), at 7.30.—H. Ll. Bassett: Nitrogen in Nature and Industry.

SATURDAY, DECEMBER 13.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—J. E. S. Dallas: Bird Life in and around London.

MONDAY, DECEMBER 15.

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Technical College, Cardiff), at 7.30. W. S. Vernon: Liquid Air.

WEDNESDAY, DECEMBER 17.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Prof. E. L. Collis: The Prevention of Industrial Diseases.

BELFAST MUSEUM AND ART GALLERY, at 8.—E. J. McKean: Ulster Folk Lore.

FRIDAY, DECEMBER 19.

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Technical College, Cardiff), at 7.30.—J. Pryde: Human Engines.

CONFERENCE.

DECEMBER 19 AND 20.

SOCIETY FOR EXPERIMENTAL BIOLOGY (at Bedford College).

Friday, Dec. 19, 10 A.M. to 1.—Dr. M. C. Rayner: Observations on *Armillaria mellea* in Pure Culture with Certain Conifers.
- J. G. Boswell: The Biochemistry of Dry Rot in Wood.
- G. E. Blackman: The Effect of Nitrogen Compounds on the Botanical Composition of Grass.
- Dr. W. H. Pearsall: Changes in the Constitution of *Beta* Leaves during Growth.
- Dr. E. D. Adrian: The Activity of Isolated Nerves and Nerve Cells.
- H. O. Bull: Conditioned Responses and Salmon Smolts.

2.15 to 4.—Dr. C. M. Yonge: The Relationship between Corals and Zooxanthellae.
- Dr. T. A. Stephenson: The Growth of Corals.
- E. Hindle: Thermophilous Organisms.
- W. H. Thorpe: Experiments on the Biology of the Petroleum Fly *Psilopa petrolii*.

5.30 to 6.30.—E. Charles: Metabolic Changes associated with Pituitary Activity.
- E. A. Spaul: Internal Secretions and Metamorphosis.

Saturday, Dec. 20, 10 A.M. to 1.—Symposium on the Permeability of Protoplasmic Membranes.
- Prof. L. T. Hogben: Electrical Conductivity and the Permeability of Animal and Plant Tissues.
- Prof. A. V. Hill: The Steady State across Biological Membranes.
- A. D. Hobson: Changes in the Sea-Urchin Egg following Fertilisation.
- R. J. Pumphrey: Electrical Potentials across the Membranes of the Trout Egg.
- C. F. A. Pantin: Surface Permeability and the Evolution of the Blood Serum.

SATURDAY, DECEMBER 20, 1930.

Dyestuffs and Applied Organic Chemistry.

THE tourney at Westminster on Dec. 4 was a joyous passage of arms in which the lances of the knights of Cobden dominated in the House of Commons, and champions of dyestuffs were driven from the lists. The ten years' chapter of protection is ended ; those worthy burghers of the textile industry who, with the chains of foreign dye merchants round their necks, knelt before Lord Moulton and prayed for deliverance, have forgotten their cry of 'never again'! Fortunately, an amendment was carried in the House of Lords on Monday to extend the Act for twelve months in order there may be a full and impartial investigation into the state of the dye industry. At the eleventh hour, therefore, it is possible that the subject will be taken from the slough of politics and considered in the light of ascertained knowledge.

It is opportune to inquire from a scientific point of view what the real effect of the Act has been, entirely apart from its financial benefit to the small group of dye-makers, who indeed have in the main devoted their profits to research £700,000 during the operation of the Act in the case of the best-known firm, which is still spending at the rate of £80,000 a year upon it. Above all else, the Act has brought into existence virile schools of organic chemistry which have rendered it possible for our young men to be trained in this subject, to make it their profession, to gain experience in its application to industry, so that they in their turn may originate, invent, and take a leading part in the establishment in Britain of new industries based on organic chemistry.

Twenty-five years ago our organic chemists were few in number and mostly trained abroad ; the excellent facilities provided being made possible by the demand for organic chemists by the foreign dyestuffs industry, then in the heyday of its most active development. The opportunity for their employment in industry at home was scanty and the reward small ; such organic industries as Britain had were only just holding their own.

During the War, when for the first time the country was thrown wholly on its own resources, the need for the organic chemist soon became apparent and extreme. Right well did the few men who were available, and the hastily trained juniors and even seniors, succeed in extemporising to fill the national needs, so that when peace ensued the nation as a whole followed willingly and with some degree of understanding those leaders who in their wisdom declared that Great Britain

must have its own flourishing, vigorous, successful organic industry, and that dyes, fine chemicals, and the like should be protected and cherished.

At once a new, attractive career for our youth had arrived; the universities were not slow to provide facilities, nor did the young men delay to utilise them. The dyestuff industry in particular readily absorbed at first all the talent available; it is common knowledge that there is no better training ground. In course of time many passed out of it again to other branches of applied organic chemistry, so that to-day Great Britain has—let us repeat, as a direct consequence of the Act—a large and growing force of experienced middle-aged organic experts, of young men occupying junior posts in the industry, and of younger men training specially for such. All are capable of understanding the potentialities of their subject, the speed at which it is developing, and are convinced of the need of Britain more than holding its own in this field if we are not to stand aside from the most promising section of future industrial advance.

Should by any chance the dye-making industry be allowed to languish in Britain, it will inevitably involve also the loss by us to the foreigner of such allied consuming industries as those of lakes, pigments, and printing inks. Ultimately, and at no distant date, we may expect to lose also the dyeing industry and the speciality sections of the textile industry itself. The manufacture in Britain, as the outcome of extensive research, of the newer, more expensive colours has resulted invariably in a reduction of price, whereas those colours which are not yet made here are maintained by the importer at relatively high prices. Much has been made by representatives of the textile industry of the alleged fact that the operation of the Dyestuffs Act has denied them access to the novelties, or at least delayed their making use of these, but they overlook how easy it will be in the future for the foreign dye-maker either to withhold his specialities altogether from the British textile customers or only to supply them at an excessive price or under such onerous conditions as, for example, an agreement to buy their whole range of dyes from him. Indeed, it will not be difficult then to build up a dyeing industry abroad, under the wing of the foreign dye-maker, supreme in quality and price, and having first or sole access to the novelties, to which factory British-made goods would have to be sent to be dyed—a step so disastrous that it is easy to foresee that it would be followed by the goods themselves being woven abroad.

Does the textile industry realise that rayon is only the first of the synthetic textile threads—the product of the organic chemist—and that it will inevitably be followed by others having novel properties, bringing with them new problems of handling or of dyeing? Is Manchester prepared to stand aside from all such developments? Why is it that the need for scientific research in modern life and in modern industry is so much more difficult to bring home to politician and people alike in Britain than in any other country? Germany owes the position its industry has attained almost entirely to its appreciation of science; America since the War owes its progress not to mass production, not to financial plethora, but to the same appreciation by president and people alike of the need for invention, new methods, new ideas, the inextricable linking of scientific research with every vital and progressive industry within its boundaries. The great industries in the United States—minerals, canning, oil, automobiles, agriculture—are alike in that in each of them there is that alliance between the chemist and the manufacturer which spells progress. Yet the House of Commons strikes a damaging and disheartening blow at this alliance, and one calculated to cripple an industry which, as a training ground alone, should be preserved, apart from the fact, which even its critics admit, that it has made good in its own field. Too much has perhaps been made of its achievements, for, as those actually engaged in the industry know, there is still much to be done, much that is difficult and costly, yet withal is attractive, as well as promising of new successes.

Britain, a small country in area, densely populated, is sadly deficient in natural resources; we have scarcely any water power, no mineral oil, no cotton, cannot grow wheat or cattle in competition with the prairies, have no oil-bearing seeds. The chemist alone can come to our rescue, and, by effecting syntheses of the materials we need from the materials we have, can assist in restoring prosperity to our manufactures and also provide employment for the population. The whole of human life is but the transmuted rays of the sun—food, clothing, nearly all that we use, are but the transformations of its energy. The organic chemist is learning at an ever-increasing rate how to guide such transformations of carbon compounds into ways which are of immediate advantage to mankind, but meanwhile he must be trained and employed. That nation will be foremost in the future which has the most and best trained chemists, above all, the nation with the clearest, sanest chemical outlook.

Newcomen and Triewald.

'he *Newcomen Society for the Study of the History of Engineering and Technology*. Extra Publication No. 1: *Marten Triewald's Short Description of the Atmospheric Engine*, published at Stockholm 1734. Translated from the Swedish, with Foreword, Introduction and Notes. Pp. xxii + 61. 12*s*. 6*d*. net. Extra Publication No. 2: *R. D'acres's The Art of Water-Drawing*. Published by Henry Brome, at the Gun in Ivie Lane, London, 1659 and 1660. With Introduction and a Diagram by Rhys Jenkins. Pp. xxiii + 43. 7*s*. 6*d*. net. (Cambridge: W. Heffer and Sons, Ltd., 1928 and 1930.)

OF all the features which distinguish the present age from those of the past, none is more strikng than that of the extended application of power o every need of man. The Egyptians, Greeks, and Romans depended on the work of tens of thousands of slaves—we to-day depend on coal and oil. The liscovery of how to produce power from the combustion of fuel must therefore ever rank as one of he great landmarks in the progress of civilisation, and the inventor of the first practical steam engine, omas Newcomen, as one of the world's greatest enefactors. That Newcomen but applied the liscoveries of others; that he invented neither he cylinder, the piston, the beam, nor the pump corporated in his engine, detracts nothing from he merits of his achievement. He it was who lved a problem which had long exercised men's ninds, and by so doing set on foot the great power ndustry of the present age.

Whatever our debt to Newcomen, however, it is unfortunate that we know comparatively little of his life and character. Such material as exists relating to him is of a meagre description, and even n the matter of his engine we are dependent on the writings of others. In these circumstances, it was a happy inspiration of the Newcomen Society to publish as their first "Extra Publication" a translation of Marten Triewald's "Description of the Fire- and Air-machine at the Dannemora Mines", a work which has long been regarded as a classic in Swedish technical literature and was the first book ever written devoted solely to the steam engine. Originally published at Stockholm in 1734, some time after Triewald had returned from his ten years' sojourn in England, it has now been translated by Mr. Are Waerland, and printed with a foreword by Mr. Carl Sahlin and a critical introduction by Mr. Rhys Jenkins, together with a bibliography of Triewald's writings.

Newcomen was born in 1663 and died in 1729; Triewald was born in 1691 and died in 1747. A man of great energy and ability, Triewald also possessed self-confidence and a firm belief in an overruling providence. Coming to England in 1716, he made the acquaintance of the scientific writer and lecturer, Desaguliers, and it was probably from him that he gained his first information on the new atmospheric engine. Among those erecting atmospheric engines at this time was Nicholas Ridley, of Newcastle, and Triewald's chance came when Ridley, "led by the wonderful foresight of God", asked Triewald to assist him. Thus embarked on an engineering career, Triewald afterwards formed a company with young Calley, the son of Newcomen's colleague, for the construction and supervision of fire-engines, and immediately after returning to Sweden in 1726 proposed to the shareholders of the Dannemora mines the erection of the Newcomen engine which is described in his book. Triewald, however, appears to have been more successful as a lecturer and writer on scientific matters than as a constructor, for the Dannemora engine was not a success and the shareholders became involved in a long correspondence and a lawsuit.

The book itself is divided into fifty paragraphs, some devoted to personal details, some to scientific theories, some to engine details, and some to suggestions regarding the uses of the engine. In this connexion it is worth observing that Triewald was probably the first to suggest using steam for pumping out a dock. At Carlscrona was the finest dock in the world, but when it was desired to dock a man-of-war, it required the services of 600 men for three days and nights to get rid of the water. An engine, Triewald says, would empty the dock in 8 or 12 hours. The engine could also be used for grain- and saw-mills, tilt hammers, for draining marshes, and for blast furnaces; but whatever it was put to, "the fire-machine is not only a tool, whereupon a very great force is brought to bear, but also the means by which this force is created, so that it can be said with good reason that all the other artifices compared to the fire-machine are merely simple tools which a craftsman is using".

The Newcomen Society has since published as its second "Extra Publication" a reproduction of R. D'acres's "The Art of Water-Drawing" of 1659, the first book in the English language on the raising of water. Only a few copies of the original work are in existence, and though of great interest, it has hitherto escaped the notice of writers generally.

Though written so early, D'acres, whose identity cannot be traced, had a good idea of the action of the atmosphere, and his work contains descriptions of bucket pumps, lift pumps, force pumps, and also of an apparatus for sucking water from wells by obtaining a vacuum by condensing steam in a somewhat similar manner to that adopted in the modern pulsometer. A conjectural sketch has been made of the apparatus by Mr. Jenkins, who for D'acres's book, as for Triewald's, has written the introduction.

New Physiology.

Human Physiology. By Dr. F. R. Winton and Dr. L. E. Bayliss. With a Chapter on The Physiology of the Sense Organs, by Dr. R. J. Lythgoe. Pp. xiv + 583. (London: J. and A. Churchill, 1930.) 15*s*.

Concerning the Statue of Liberty in New York Harbour, Clemenceau is alleged to have remarked that the French people also had memorials to the illustrious dead. During the past few years there have appeared several revised editions of the standard works on human physiology used by medical students fifteen or twenty years ago. The changes necessitated by the rapid strides which physiology has made during the intervening period are extensive; and the advisability of putting so much new wine into old, if illustriously old, bottles is questionable. In chapter after chapter a short postscript on the discovery of an oxygen is added to a lengthy exposition of a phlogiston hypothesis. In the mind of the student who approaches his studies in this way confusion is inevitable. In the labyrinth of Nature the path of scientific discovery is often tortuous. One expedition after another ends in a cul-de-sac, from which the inquirer must needs retrace his footsteps and make a fresh start. To the philosopher and student of scientific method such reverses are meat and drink. They only bewilder the beginner.

Winton and Bayliss have produced a text-book in which they have set out to expound what is known about physiology to-day. They have not encumbered their exposition with a catalogue of the mistakes of our illustrious predecessors. They have not assumed that the time devoted to elementary zoology is exclusively confined to architectural mnemonics intended to recall the foramina of the dog's skull or the pontifical polysyllables associated with the appendages of the crayfish. From the first to the last page they have confined themselves to the kind of information which a medical student who has surmounted the stile of the first professional examination may reasonably expect from a course of physiology bearing directly on the practice of medicine. The information is presented with lucidity and good humour. The book is a highly creditable performance. The authors are to be warmly congratulated on their task.

Apart from the rapid progress of physiological science during the past few decades, there are several extrinsic reasons which prompt a demand for a new tradition in the teaching of medical physiology in Great Britain. One is the new temper in British zoology. A generation of younger professors, including Dr. D. M. S. Watson, himself a distinguished palaeontologist, are insisting that zoology, as its name implies, is the study of animals rather than corpses. Consequently, it is becoming possible to relegate the experimental anatomy of the organs to an earlier stage in biological instruction. Under the influence of Dr. Charles Singer the history of medicine is rightly asserting its claims to rank as an independent branch of study. There is therefore less need to subordinate the inclusion of vital contemporary issues to the historical presentation of the individual sciences. Winton and Bayliss have wasted no space in 'flogging dead horses'. They have made no attempt to deal with those aspects of physiology which have developed more particularly in connexion with the study of the lower organisms and may now be safely entrusted to the teaching of experimental zoology. They have succeeded in writing a book which is suitable for the medical student, omits nothing which is of vital interest to the present generation, and spares no effort to familiarise the reader with laboratory methods and experimental data on which modern physiological principles rely. Their presentation of the new work on muscle and nerve, reflex action and the special senses, endocrinology and reproduction, shows that there is room for a higher standard in medical instruction so soon as those engaged in teaching physiology are willing to devote less attention to effete themes and superannuated topics.

Throughout the book there is a careful attention to the definition of terms. On page 1 we are reminded that "health and disease are primarily sociological concepts", a truism overlooked by many physiologists and by nearly all psychiatrists and eugenists. The phraseology is felicitous, and the authors consistently encourage those "who have acquired the rare faculty of being able to suspend judgment without undue discomfort to take the opportunity to exercise it". In dealing with the special senses and with the mechanism of behaviour

the writers adhere to a strictly objective nomenclature more rigidly than the authors of earlier works. The remarks upon speech are an exception to their general practice. No one will disagree with the statement that "such relations have not yet been analysed in objective terms" (p. 446). Their statement that "considerable progress has been made in this field by the methods of introspective psychology (*e.g.* psychoanalysis)" is open to the objection that, if any conceivable progress in such matters is due to professional psychologists who still adhere to an introspective terminology, it is because they have actually employed methods analogous to those which the physiologist uses.

American Oil Fields.

Structure of Typical American Oil Fields: a Symposium on the Relation of Oil Accumulation to Structure. Forty Special Papers including a Critical Summary, in part from the Program of the Twelfth Annual Convention of the American Association of Petroleum Geologists at Tulsa, Oklahoma, March 24, 25 and 26, 1927. Vol. 2. 1929. Pp. xxiii + 870 + 4 plates. (Tulsa, Okla.: The American Association of Petroleum Geologists; London: Thomas Murby and Co., 1929.) 27*s.* net.

THE origin, migration, and accumulation of petroleum: three outstanding episodes (in proper sequence) in a natural history even now imperfectly understood. Every text-book on oil geology gives a chapter to each: every author reiterates the same arguments which have held sway since the enlightened days of Redwood, Engler-Hofer, and their contemporaries. 'Origin', as such, has a literature of its own, much of it unconvincing to a degree. Migration of petroleum is a subject still in a state of flux and kept so by the contradictory results of experiment and conflicting tenets of modern philosophy. 'Accumulation' is the oil-pool itself, how and why it came to be formed, what its relationship to reservoir-rock really proves to be, what its disposition anent structure actually signifies. In the last case we are on more solid ground because the unravelling of subsurface conditions of so many oil fields to such a point of accurate detail has provided us with tangible evidence of the *raison d'être* of many a big pool.

Our American friends enjoy nothing better than to take stock of a situation, scientific or otherwise, preferably by means of large-scale conferences. 'Accumulation' in itself furnishes an excellent theme for one of these debates, which, in published form, occupies two large volumes. This is the second, in matter, style, and presentation similar to the first.

If the reader can wade through the mass of detail given in each of these studies of American oil-pools, his knowledge of accumulation will be almost rare. If detail appals, he may emulate without shame that type of novel-reader who weakly scans the end pages to see if it has a likable ending or plot, or whose patience tires before the half-way chapter; only in the present instance, the last paper, by F. G. Clapp, not only reveals the essence of all that has gone before, but also it is by far the best contribution of all, and, if for no other reason, this volume merits attention. Apart from this, the papers making most appeal deal with such famous pools as Long Beach, California; El Dorado, Kansas; Caddo, Louisiana; Cushing, Oklahoma; Yates, Texas, and Salt Creek, Wyoming; perusal of these is worth while if other sources of relevant information have not previously been consulted.

There are probably few types of oil-pool in the world not amply illustrated by the examples quoted in these two books, and one wonders whether, under the heading of 'accumulation', we have very much more to learn and, be it admitted, to what extent symposia really advance our learning.

H. B. M.

'How it was Made' in Antiquity.

The Technical Arts and Sciences of the Ancients. By Albert Neuburger. Translated by Dr. Henry L. Brose. Pp. xxxii + 518. (London: Methuen and Co., Ltd., 1930.) 42*s.* net.

THIS is a disappointing book, and scarcely worth the great labour of an English translation, or the translator's occasional attempts to patch it up; and as the bibliographies of the German original have been omitted, it is impossible to check or follow up many remarkable statements without reference to it. But considering the immense field which it is designed to cover, and the very defective materials available in many parts, it is a remarkable compilation, and justifies the translator's contention that the achievements of the ancient world have been unduly overlooked in matters not only of industrial technique but also of scientific experiment.

Dr. Neuburger complains that often his predecessors have been insufficiently acquainted either with the ancient languages or with modern experience in the same arts and industries. But his book will perpetuate hardy misconceptions,

on both sides: and some which were already cleared up when he began to collect his material. This is part of the price that a very learned nation has to pay for its prodigious output of *thesis* and *programm*, and for the rapidity with which, in historical studies at all events, wild guesses gain and lose acceptance. A man must be something of a specialist in general knowledge to gather only good grain where there is so much chaff.

Take the chapters in the present volume on metallurgy. What evidence is there that the "Germanic races . . . became acquainted with copper long after they had used iron" (p. 13); that the Phœnicians obtained metallic tin from India (p. 15); that Herodotus "makes special mention" of the Cassiterides (p. 14) except to deny knowledge of them; that the Corinthian clay-tablets depict smelting furnaces (p. 11), not pot-kilns; that Spartan boys played with lead soldiers (p. 19); that the iron column at Delhi is dated to the ninth century B.C. (p. 21), or that iron was worked in India in 2500 B.C., or even in 1500 B.C., or cast-iron in 1400 B.C. (p. 22); that Thothmes III. took great booty in iron spears (p. 22)? The Egyptian furnace in Fig. 24 was not a 'bloomery', but for gold working, as the (omitted) inscription shows. Nor does the iron "generally flow out", or it would be cast-iron and useless to ancient smiths (p. 26); nor is chrysocolla identical with malachite (p. 46); nor galena with lead-oxide (p. 48). On p. 119, it is difficult to see how lead sulphate could result from alteration of black-lead. An Athenian *stater* equalled two *drachmæ*, not four.

The chapters on pottery are not much better. The *crux ansata* (p. 131) is not the same as the *swastika*, nor is either ornament found on "all fired clay of the first-period", nor even, if it were, would it prove that the "cradle of the clay industry" was in Asia Minor or in Egypt—which are really quite different countries. The "art of varnishing glaze" (p. 132) looks like a mistranslation, for *Firniss* includes vitreous glaze; "ordinary clay stones" is perhaps another (p. 132). But the descriptions of the Greek potter's wheel (Fig. 204) and of the technique of 'red-figure' painting are nonsensical. On p. 144 and p. 151 distinct and discrepant accounts are given of ancient "black-glaze", and on p. 142 it is stated that the first object in thus glazing pots was to make them waterproof. That certain colours were "always applied under the glaze" (p. 143) is unlikely, as they would have been invisible.

There are some wrong references to ancient authors, and some queer mistranslations. Of Xerxes' Bridge, the popular rendering of Herodotus vii. 36 is repeated, though a 'science-man' should have detected its absurdity. In the account of "Oils and Fats", on p. 113, "reels" should probably be "tackle", "see-saw" should be "lever"; p. 114, "buttress" should be "clamp", and the whole mechanism is misunderstood. On p. 117, "notch" should be "knot" (as in knot-grass); on p. 118, is "combusting" correct? On p. 464, "stretches" should be "stretchers".

In spite of obvious defects, for popular purposes the book brings together a very large mass of information on a side of ancient life which is in many ways curiously like our own. J. L. M.

Our Bookshelf.

Aircraft Instruments. By C. J. Stewart. Pp. xix + 269 + 30 plates. (London: Chapman and Hall, Ltd., 1930.) 21s. net.

ONE'S first feelings upon picking up this book are that here is a volume that deals with the application of a somewhat nebulous physical science to concrete engineering problems, written by an author singularly competent to link up the two subjects. Unfortunately, the subject is not dealt with from that point of view to anything like the extent possible. The author principally confines himself to the description of apparatus and its use, doubtless with an eye upon the size and readability of the book. There are, however, ample references to relevant publications that enable the subject matter to be followed up if desired. The chapter on the measurement of height is a happy exception to this criticism. It is probably the most comprehensive study of this question published to date.

Major Stewart seldom passes opinions upon the instruments described. There is nobody more competent to do so, both by reason of his extensive experience and of the position that he now holds as head of the Instrument and Physics Department of the Royal Aircraft Establishment. For example, in the chapter on compasses, he describes the selenium cell distant reading type. One feels certain that this is an interesting laboratory experiment at present, rather than a practical aircraft instrument.

The book is certainly the most comprehensive description of aircraft instruments that has yet been published. Incidentally, the photographs and diagrams are very well chosen as illustrations to the text, and are not mere padding, as is so often the case. A device in many of the R.A.F. official photographs, of including a portion of a scale, is very helpful in giving an impression of the size of the objects.

The subdivision of the book is logical and easy for reference. The instruments are classified under

their functions, which facilitates their comparative study as types.

The descriptions are not confined to British instruments, all the better-known foreign makes being included. An interesting chapter deals with the methods of measuring actual height above the ground immediately beneath the aircraft. This problem is very much in the minds of aircraft operators, and is by no means successfully solved yet.

The Victorian Tragedy. By Dr. Esmé Wingfield-Stratford. Pp. ix + 296. (London: George Routledge and Sons, Ltd., 1930.) 10*s.* 6*d.* net.

WHY 'tragedy'? One reads Dr. Wingfield-Stratford's new and brilliant book through with growing wonder. He meets so fully all the cheap gibes against the last generation—the ineffectual politicians, the hypocritical moralists, the fainting women, and all the rest of it—and shows the contrary truth of an age of exceptional earnestness, industry, and success—"the heyday of idealism and imaginative genius"; and then sums it up as a "tragedy". What does he mean? Dr. Wingfield-Stratford's answer is that the Victorian middle class was 'tragic' because its members went on their earnest and triumphant way quite unwitting of the catastrophe which was to follow and of the greatest social and industrial problem which remained to be solved. The latter was the humanising of the industrial revolution, the widening of the conquest of Nature which the nineteenth century initiated with scientific machinery into a conquest of human conditions, the addition of an ideal of beauty to that of wealth.

No doubt on this side our Victorian ancestors were defective; but it was they who first proclaimed the need of the change, through Ruskin, Morris, Carlyle, and a host of other prophets and workers. Unhappily, it was a far easier and quicker process to make cotton goods in a factory than happy and intelligent workers in garden cities. The mechanical process outstripped the moral; but it is mere ignorance and ingratitude to overlook the fact that the mechanical conquest of Nature made possible the vast extension of health and well-being of all kinds which the inheritors of the Victorians now enjoy. Dr. Wingfield-Stratford, of course, does not fall into this gross error, and he has given us a book which is delightful to read for its wit, enthusiasm, and good stories, while it constantly raises big questions such as we have discussed above.

F. S. M.

The Fauna of British India: including Ceylon and Burma. Published under the Authority of the Secretary of State for India in Council. Edited by Lieut.-Col. J. Stephenson. *Cestoda.* Vol. 1. By Dr. T. Southwell. Pp. xxxi + 391. (London: Taylor and Francis, 1930.) 22*s.* 6*d.*

THE investigations of the late Sir William Herdman on the pearl fisheries of Ceylon, begun in 1902, suggested infection with larval cestodes as a cause of pearl formation and thus directed attention to the cestode parasites of fishes found in Indian seas. The reports on these by the late Sir Arthur Shipley and Mr. James Hornell were followed by a series of papers by Dr. Southwell, who later turned his attention also to the cestodes of Indian land vertebrates. Since the War a number of other helminthologists have given a good deal of attention to Indian cestodes. Dr. Southwell has now produced the first volume of a monograph which will be found of great value as bringing together the results of all these researches, hitherto scattered in many scientific periodicals.

The volume deals with those families that include most of the fish-infesting species, and contains an introduction giving a useful account of the structure and classification of the group. The illustrations are numerous and excellent. A little more care in the arrangement of the matter would, in some places, have made the book more easy to consult for those who are not specialists. The hasty reader, finding on p. 344, for example, the names *Thysanobothrium uarnakense* and *Parataenia elongatus* standing in black type at the head of paragraphs of description, may waste some time in discovering that these are regarded as synonyms of *Polypocephalus radiatus* described on p. 342. In the preface it is pointed out that "the field is largely unexplored, and it is clear that in the near future additions to our knowledge are likely to be made on a large scale". This desirable result will no doubt be hastened by the publication of Dr. Southwell's volume.

Thomas Aquinas. By Rev. M. C. D'Arcy. (Leaders of Philosophy Series.) Pp. ix + 292. (London: Ernest Benn, Ltd., 1930.) 12*s.* 6*d.* net.

THE extent of the writings of St. Thomas Aquinas and the vastness of his system make it a very difficult task to condense his philosophy within the compass of three hundred pages. Yet Father D'Arcy has succeeded in presenting the fundamental principles of the Angelic doctor's system in a concise and accurate form.

Although St. Thomas shared many of the naïve beliefs of his contemporaries, he was aware of the provisional character of much science and skirted its treacherous sands when he wished to establish a truth definitely. The physical universe as St. Thomas saw it is the one made familiar to us by Aristotle and the Ptolemaic system; nevertheless, he puts in quietly the *caveat* with his cautious "if it be true". So that his scientific beliefs have little bearing on the fundamental aspects of his mental and moral philosophy. Indeed, in revising St. Thomas's teachings, his modern followers have given up with good grace his astronomical beliefs, his theory of the four elements, of the influence of the air and the sun, of motion, of the physical, chemical, and biological conceptions which entered into his philosophy of substance and change. The bibliography at the end of the book shows that much has to be done in Great Britain for the study of St. Thomas, who had, after all, a considerable influence in the Middle Ages. If Father D'Arcy's book awakens the interest of his readers in that direction, his labours will not have been in vain.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Molecular Field and Atomic Order in Ferromagnetic Crystals and in Hydrogenised Iron.

THE molecular field postulated by Weiss to explain ferromagnetism is regarded by Becker[1] as mechanical in origin, representing the control exerted by strain within any portion of a crystal upon the direction in which that portion may retain its magnetisation in the absence of externally applied magnetic fields. More recently, Becker and Kirsten[2] have discussed some interesting experiments upon the magnetisation of nickel under tension. They arrive at the conclusion that, at least for applied fields much larger than the coercive force — which becomes as small as one or two gauss under their extreme conditions — the magnetisation may be predicted quantitatively from the maximal magnetostrictive shortening of well annealed metal and the saturation intensity of magnetisation, both of which quantities are sufficiently well known from previous experiments by others. Their account of the effect of internal stresses over the cross-section of a wire specimen upon its magnetisation is also very satisfactory. They point out, in the second footnote to p. 660, that the "extremely irreversible processes" observed in weak applied fields are not correctly represented by Becker's theory, magnetic changes being observed at field values which are less than the theory predicts as necessary for their occurrence.*

Two other recent notes which present apparently contradictory opinions regarding the molecular field are by Frenkel and Dorfman[3] and by Akulov.[4] In the former, the energies of magnetisation and of the quasi-magnetic separation of a crystal into elementary regions magnetised in different directions are used in computing the minimum and average volumes of the magnetically saturated regions postulated by Weiss. In the latter, it is argued that such magnetic saturation of small regions is incompatible with the observed magnetic behaviour of iron macro-crystals, and that therefore the internal energy of partially saturated states must be nearly the same as that of the saturated state.

A fourth position of interest in the present connexion is that taken by Gerlach,[5] who thinks that his own experiments and those of others are consistent only with the complete absence of magnetic hysteresis in perfect crystals of iron. Against this it may be urged that the hysteresis losses in the polycrystalline hydrogenised iron of Cioffi[6] are at least as low as in any mono-crystalline iron yet described.

My recent studies on magneto- and elasto-resistance[7] have led me to suppose that the electrical resistance of a crystal in which the atomic magnets have been rendered parallel by magnetisation or by mechanical strain is sensibly the same whether the magnetic axes of the elementary magnets all point in one direction — corresponding to magnetic saturation — or point indifferently in either direction — corresponding to magnetic neutrality. The two states have been distinguished in a paper before the American Physical Society[8] as, respectively, 'magnetic' and 'mechanical' atomic order. This distinction affords a convenient starting-point for a more precise treatment of ferromagnetism which may lessen the confusion of opinions noted in the papers first referred to herein.

In agreement with Becker, then, we may regard the molecular field of Weiss as wholly mechanical in origin.† Since, however, the strain tensor does not fix the direction of the magnetic vector, we will suppose that a given strain may, in the absence of an applied magnetic field, be associated with any degree of magnetisation, of either sign, in the preferred direction. We must also suppose that the differences in internal energy between the various *magnetic* complexions associated with a given strain are small in comparison with the energy of the strain. This is the more likely because we know that the electrical resistance and the length in the direction of alignment are almost unaffected by changes in magnetisation under these special conditions. This amounts to saying that the reversal of an atomic magnet involves little change in the internal energy of the crystal to which it belongs.

We differ from Akulov in supposing that an atomic magnet can pass from one strain-favoured direction to the other without necessarily dissipating the energy required *per atom* in changing the common direction of all the atomic magnets from the initial direction to an intervening position for which the internal energy is greater. Akulov, for example, sets the minimum hysteresis loss per cycle for reversal of magnetisation along a <100> direction at twice the energy difference for complete magnetisation along <110> and <100> directions. This loss, as Akulov points out, is absurdly too great. We avoid his difficulty by denying that in the reversal of magnetisation along a <100> direction the assembly of atomic magnets ever has any other common direction. We are thus able to go through cycles of magnetisation without working against the molecular field.

We cannot, however, go so far as Gerlach does in denying hysteresis losses altogether. The reversal method of changing magnetisation must still involve some dissipation of energy, because, for one thing, there must be resultant eddy currents in the adjacent metal. This loss will not depend upon the frequency of traversing the cycle if, as seems safe to assume, the reversals are as quick as other atomic energy jumps. We will therefore regard the low values of coercive force which Gerlach and others have attained as closely approaching the limit to which perfect atomic order would permit us to go. The low values of coercive force reached by Becker and Kirsten by stretching nickel are still far higher than this limit, and, indeed, the strains under even their extreme stresses must have been far from homogeneous on an atomic scale. The imperfections of real crystals may prevent our ever quite attaining the ideal case by purifying and annealing.

If these hypotheses are correct, the calculations of Frenkel and Dorfman, which depend for their validity upon magnetic saturation of each elementary region, are no longer valid.

The effect observed by Cioffi is distinctly mo

* It may also be mentioned, though the facts are not pertinent to the present discussion, that the theory of the distorted dipole lattice, as the authors themselves state, predicts a magnetostriction of the wrong sign and amount, and that the similarity in the magnetic behaviour of cold-worked and annealed specimens under great tension is not surprising, in view of the fact that such tension is reported to have stretched the annealed specimen by so much as 10 per cent.

† This opinion has, of course, been held by others than Beck
My first explicit statement of the hypothesis was made in connexion with the magnetostriction of permalloy (*Phys. Rev.* [2], **28**, 158-166; 1926), where I said: "The more or less random stresses in ordinary metals would, in accordance with the views here expressed, do that for which this molecular field [of Weiss] was evoked, for they would in the case of all but favourably oriented atoms tend to maintain the established direction of magnetisation against small disturbances, and thus confer upon magnetisation that stability which the simple interaction of freely turning magnets cannot furnish".

puzzling. It is suggested as possible that hydrogen[8] dispersed throughout the lattice of iron crystals—not at lattice points—may act catalytically in the following way. Some of the iron atoms immediately adjacent to hydrogen atoms are thereby strained in a manner that favours increase in magnetisation by their reversal along the direction of the applied field. We know nothing of the manner in which hydrogen atoms conduct themselves in iron at room temperature, but it is at least possible that a single hydrogen atom may wander about sufficiently to strain in the favourable way a great many iron atoms in succession at each low value of the applied field. If this is the process involved, the hydrogen atoms must repeatedly lose their energy of thermal agitation, and therefore the iron must be cooled during the process and the energy must be supplied from outside by thermal conduction and by the magnetic field. If, as is the case, the reduction of area of the hysteresis loop is by more than 50 per cent, there will be a net cooling during each cycle, the hydrogenised iron being a refrigerating engine worked by cyclic magnetisation. Experiments with alternating magnetic fields should be competent to fix not only the amount of cooling integrated over many cycles, but also the time interval required for the complete promotion of magnetisation at each increment in magnetic field by the necessary random migration of hydrogen atoms.

This explanation would be much more fanciful if we had not recently learned from the experiments of Ellwood[9] that cooling may occur at certain stages in a hysteresis cycle, and that the heat developed in the whole cycle may be less if the cycle is traversed in many steps so that there are periods of ageing under the important applied fields. In Ellwood's case, carbon, not hydrogen, is known to have been present, and carbon is also known to enter the lattice of iron not at lattice points but by crowding into interatomic spaces. Its diffusion rate in iron at room temperature would be expected to be much less than that of hydrogen.

On these views, the possible ways in which magnetisation may change are two: (1) by reversals, without sensible magneto-resistance changes or magnetostriction, and with small but definite hysteresis losses probably closely conditioned by electrical conductivity; and (2) by rotations through less than 180°, with magneto-resistance and magnetostriction, with hysteresis losses of important amount largely controlled by mechanical strains inherent or induced by applied stresses, and possibly subject to catalytic acceleration.

Unit of Atomic Weight.

THE discovery of the complexity of oxygen clearly necessitates a reconsideration of the scale on which we express the weights of atoms. Owing to the occurrence of O^{17} and O^{18}, now generally accepted, it follows that the mean atomic weight of this element, the present chemical standard, is slightly greater than the weight of its main constituent O^{16}. The most recent estimate of the divergence is 1·25 parts per 10,000. This quantity, even apart from its smallness, is not of much significance to chemists, for the experience of the last twelve years has shown that complex elements do not vary appreciably in their isotopic constitution in natural processes or in ordinary chemical operations. Physics, on the other hand, is concerned with the weights of the individual atoms, and by the methods of the mass-spectrograph and the analysis of band spectra it is already possible to compare some of these with an accuracy of 1 in 10,000. Furthermore, the theoretical considerations of the structure of nuclei demand an accuracy of 1 in 100,000, which there is reasonable hope of attaining in the near future. The chemical unit is clearly unsuitable, and it seems highly desirable that a proper unit for expressing these quantities should be decided upon.

The proton, the neutral hydrogen atom, one-quarter of the neutral helium atom, one-sixteenth of the neutral oxygen atom 16, and several other possible units have been suggested. None of these is quite free from objection. It is desirable that this matter should be given attention, so that when a suitable opportunity occurs for a general discussion of the subject, each point of view may be afforded its proper weight in arriving at a conclusion.

The Geological Importance of the Radioactivity of Potassium.

DR. A. HOLMES and Dr. R. W. Lawson in their paper on "The Radioactivity of Potassium and its Geological Significance" (*Phil. Mag.*, Dec. 1926, p. 1218) have estimated the heating effect of potassium by multiplying the average energy of the emitted β-ray by the number emitted per second. The energy can be obtained from the β ray absorption coefficient, and the number emitted per second from the half value period. From the best data at the time available, they decided that the energy was $7{\cdot}3 \times 10^{-7}$ erg, and the half value period $1{\cdot}5 \times 10^{12}$ years: that is, about 225 β rays are emitted per second per gram of potassium.

The recent work of W. Muhlhoff (*Annalen der Physik*, vol. 7, p. 205; and NATURE, Nov. 22, 1930, p. 823) leads, however, to a very much lower value. By the use of a Geiger and Müller sensitive particle counter he counts directly the number of β-rays emitted per gram of potassium; and obtains a value of 23 β-rays per second: not 225. This means that the heating effect will be reduced to one-tenth of its previously estimated value.

This result is important in connexion with a theory of the surface history of the earth advanced by me. For it increases the estimated period required for the thermal development of a 'revolution'; and in this manner contributes towards agreement with estimates of geological time based on the lead ratios of uranium and thorium as found in the rocks.

Internal Conversion of Nuclear Energy.

WHEN a nucleus passes from an excited state into a state of lower energy, two different processes may occur: either a γ-quantum is emitted or one of the extra-nuclear electrons thrown out of the atom (with an energy equal to that of the γ-quantum minus the ionisation energy of the electronic level); in this case we speak of internal conversion of nuclear energy.

For a theoretical calculation of the probability of internal conversion, we have to know the interaction between the atomic electron and the excited nucleus. As is well known, the problem is different according as the distance is large or small compared with nuclear dimensions. On large distances the action of the excited nucleus can be described as the field of a Hertzian doublet. The part of the probability of ejection caused by the interaction in this region may be written as the product of the total number of γ-quanta emitted, times a factor K—depending only on the wave-length of the γ-ray—which we will call the coefficient of internal photo-effect.

In order to determine whether this effect, or the effect caused by the interaction in the nuclear region, is the more important for the ejection of atomic electrons, one has to evaluate the coefficient of internal photo-effect and compare it with the experimental data. The first calculations of this kind were carried out by Miss Swirles [1]; as, however, these calculations are based on non-relativistic wave mechanics, the results obtained cannot be expected to hold when the energy is large compared with mc^2, which is the case for most of the γ-rays investigated. It is necessary, therefore, to deduce a relativistic formula. Using Dirac's equation and assuming, for simplicity, that the energy of the γ-quantum is large compared with mc^2 ($5 \cdot 1 \times 10^5$ volt) I arrive at the following expression:

$$K = \frac{1}{Z} \cdot \frac{1}{\rho} \cdot \; \cdot (2\alpha)^{2\sqrt{1-\alpha^2}} \cdot \frac{\left|\Gamma(\sqrt{1-\alpha^2} - i\alpha)\right|^2}{\Gamma(2\sqrt{1-\alpha^2}+1)} \cdot e^{-2\alpha \arccos \alpha}$$

where $\alpha = \frac{Ze^2}{hc}$ and ρ the ratio of the momentum of the ejected electron to mc. Putting $Z = 83$ (RaC) we find:

$$K = 0 \cdot 82 \times 10^{-3} \cdot \frac{1}{\rho}$$

The ratio of the number of ejected electrons to the number of γ-quanta emitted for radium-C has been measured by Ellis and Aston.[2] These values are given in the second column of the accompanying table; the last column gives the theoretical values of internal photo-effect:

Energy of γ-ray in volts $\times 10^{-5}$.	Measured internal conversion $\times 10^4$.	Calculated photo-effect $\times 10^4$.
6·12	61	4·6
7·73	48	3·7
9·41	61	3·3
11·30	62	2·8
12·48	57	2·6
13·90	14	2·4
14·26	10^4 (?)	2·3
17·78	16	1·8
22·19	13	1·6

From this table we see that the number of ejected electrons is much larger than the number we could expect from internal photo-effect. This means that for the hard γ-rays of radium-C the ejection of atomic electrons is mainly due to the interaction in the nuclear region.

An attempt to estimate this effect was recently made by R. H. Fowler,[3] with the assumption of the Coulomb law of interaction between the atomic electron and an α-particle, moving in a potential box. The probability of ejection, calculated in this way, is too small to account for the discrepancy between the experimental values and the theoretical values of internal photo-effect. Fowler, also, uses non-relativistic wave mechanics. It may, however, easily be seen from general considerations that also in the present relativistic theory the effect always will be much smaller than the internal photo-effect. Clearly we are here outside the limits of applicability of relativistic wave mechanics. In these circumstances it is scarcely justified to lay too much stress on the agreement between Fowler's calculations and experiment for the β-ray line $14 \cdot 26 \times 10^5$ volt. The only thing independent of special ideas about the interaction is that one would always expect the effect to be about proportional to the probability density of the ejected electron in the nucleus ($r \to 0$). This is actually confirmed by the experiments about conversion in other than the K-levels. The electrons are ejected by hard γ-rays only from such levels as K_1, L_1, M_1, . . ., where the density at the origin does not vanish. For the ratios of the densities in the nucleus for a $2S$ and a $1S$ state we find (in the relativistic theory) 0·15 in good agreement with the experimental ratios of the coefficients of internal conversion in the L- and K-levels.

Electric Conduction in Metals.

THIS note has reference to the very interesting paper by Mr. R. H. Fowler in the Supplement to NATURE of Oct. 18 last on the conduction of electricity in metals. In this he refers to the difficulty in connexion with Drude's model in that the free electrons in the spaces should behave like a perfect gas, and so affect the specific heat relations. As experience shows that this is not so, the inference is drawn that the dynamics is wrong and we must invent a new one. But another inference would seem more natural: that the conclusion that the electrons behave like a perfect gas is wrong and we must seek the reason why. I think this is not far to seek, and the error lies in supposing that the *same* electrons are continuously in the free space. This may be illustrated by taking the theory of emission as proposed recently by me in the *Philosophical Magazine* (**8**, 108; 1919). Shortly put—the nucleus decides what particular orbits of electrons round it are to fall in, the energy of fall goes to the nucleus, and the nucleus radiates according to the $nh\nu$ law. Conversely, the reverse process also takes place. When radiations fall on the atom it absorbs those of its special periods, and when it has absorbed the quota $h\nu$ it raises an electron to a corresponding outer orbit. This then falls in and its energy is radiated again by the nucleus. Amongst these operations, some will be due to free electrons falling in, and a similar set being set free. Consequently, the free electrons in the interatomic spaces will be continually passing in and out, and they never have time to take up the energy due to the temperature of the space. The time required for this must be considerable, measured in terms of the mean interval between collisions.

The theory explains, further, the remarkable fact that a single atom behaves as a smooth sphere—or, in other words, its internal system appears dynamically isolated. In the early days of the theory of the rigid atom, the hypothesis of a smooth sphere completely explained the difficulty. But an atom consisting of a nucleus and a number of electrons circulating round it carries with it difficulties as to the equal distribution of energies between the large number of degrees of freedom involved. This difficulty disappears on the present theory. An electron entering

the domain of an ionised atom dissipates its energy until it takes up some critical orbit. Then it falls to its normal place of lowest energy in the system. The energy goes to the nucleus and is promptly got rid of by radiation. *Or*, conversely, in a hot region, the temperature radiation of the space falls on the nucleus and those of the critical periods only are absorbed. The energy is then got rid of by the reversed process. In this way the mean internal energy of the atom remains the same always, and it behaves apparently as an isolated dynamical system. The atom itself would appear to have the structure of a perfect machine. W. M. HICKS.

Change in Electron Coupling in the Rare Gases.

HOUSTON (*Phys. Rev.*, **33**, 297; 1929) has worked out an approximate quantum mechanical theory of the relation of the triplet interval ratio to the singlet-triplet interval for two electron configurations in which one of the electrons is in an *s*-state; he has also derived expressions for the *g*-values and for the intensities. Those formulæ show the variation with change of coupling.

Recently Laporte and Inglis (*Phys. Rev.*, **35**, 1337; 1930) have applied Houston's results to configurations like p^5s and d^9s by considering the invariance of the configurations p^5 and d^9 with changing coupling and taking the spin-orbit interaction and coupling factor with negative sign. The only spectrum in which the calculated *g*-values could be compared with experimental values was that of Ne I. In that spectrum Back (*Ann. der Phys.*, **76**, 329; 1925) has measured the *g*-values of the singlet and middle triplet level of the configuration $2p^53s$. The experimental data on the Zeeman effect of the rare gases which I have at my disposal, from my work on this subject in Prof. Zeeman's laboratory, enable me to give experimental *g*-values of the analogous levels of the configuration $3p^54s$ in A I and $4p^55s$ in Kr I. In the spectrum of Xe I only the *g*-value of the middle triplet level of the configuration $5p^56s$ could be measured. The following table gives the comparison of experimental and theoretical values.

g-values.

Paschen.	Russell-Saunders		(*SL*) coupling.	Ne I.	A I.	Kr I.	Xe I.	(*JJ*) coupling.
	$^1P_1$	obs						
		calc.	1·000	1·036			1·281	1·333
	$^3P_1$	obs.		1·464	1·40	$1{\cdot}24^5$	1·18	
		calc	1·500		1·399	1·243	1·219	1·166

The agreement of the observed and calculated *g*-values is very satisfactory in the cases of Ne I, A I, and Kr I. The agreement is not so good in the case of Xe I, due probably to the fact that the first order perturbation calculations do not hold for very large values of the spin-orbit interaction.

A more detailed description of the measurements will be given elsewhere. C. J. BAKKER.

Surface Films.

READERS of Dr. Langmuir's stimulating and detailed review of my book, "The Physics and Chemistry of Surfaces" (NATURE, Nov. 8), may possibly suppose that there is an important difference of opinion on fundamental questions of the structure of surface films, from the criticism which he makes of one remark in the book. This I do not believe is the case; the differences, if there are any, relate to points of detail only. Dr. Langmuir appears to think I am disputing the fact that the heads of the molecules anchor them to the water and so cause spreading from bulk material on the surface; but this fundamental fact, which he himself established, is not doubted by any worker in this field, so far as I know, and has been confirmed *without exception* in many thousands of my own experiments. It is rather important that no impression of disagreement should be given on this matter: the water-soluble or 'polar' group unquestionably anchors the molecules to the surface, and if the attraction of this group is weakened sufficiently, the film either becomes unstable or cannot be formed at all. This anchoring is equally important in all classes of films, condensed, expanded, and gaseous.

My suggestion on page 75, "that the heads tend to hold the molecules together, while the chains try to disrupt the film", may be better for some explanation, since taken out of its context it is liable to be entirely misleading. It applies only to the 'liquid expanded' state of the films, and the disruption considered is a surface 'evaporation', or escape of the molecules laterally from coherent islands of monomolecular film, to form gaseous films, not a disruption by collapse of the film to form aggregates on the surface. The liquid expanded state is intermediate between the most coherent state, the condensed, and the least coherent state, the gaseous, in which there is so little lateral adhesion between the molecules that they move about independently in the surface like a two-dimensional gas. In all these states, the molecules are anchored to the water by their heads; in the condensed, they are held together in coherent islands by the lateral adhesion of both heads and chains; in the gaseous, the lateral adhesion has been practically completely overcome. In the expanded, my suggestion is that the thermal agitation has reached an amount sufficient to overcome the lateral adhesion between the chains, but that there still remains enough adhesion between the heads to prevent separation of the molecules completely. This would mean that the chains are whipping about violently, the restraints on their thermal agitation having broken down more or less completely; the heads of the molecules near the water are, however, exercising a restraining force, keeping the molecules from flying off laterally along the surface.

This suggestion is not more than a speculation, yet I believe it is the best and indeed the only tenable one of the many speculations which have yet been made as to the structure of the liquid expanded films. The principal facts to be explained are these: the films are coherent, with but a small surface vapour pressure; their area is two or three times the minimum area to which the molecules can pack in the surface; they are not formed unless there is a good deal of residual affinity in the heads of the molecules, series of compounds in which the residual affinity in the heads is small passing straight from the condensed to the gaseous (or sometimes 'vapour expanded') films; they are formed from condensed films (provided there is sufficient residual affinity in the heads) by rise of temperature, a higher temperature being required the longer the chain in the molecule, which indicates that all, or some part of, the lateral adhesion between chains has disappeared in the liquid expanded films.

My principal doubt in regard to this explanation is as to the propriety of separating in this clear-cut way between the adhesions due to the chains and those due to the heads. It seems scarcely likely that the adhesions can break down completely throughout

the length of the chains and still remain intact at the heads. Also, there is some difficulty in picturing the mode in which the heads can hold the molecules together when these are separated to two or three times their normal (areal, not lineal) spacing. My suggestion, which was made in 1928, is really the reverse of an earlier suggestion of Dr. Langmuir's, that in these liquid expanded films the heads are trying to be free as in the gaseous films, while the chains are restraining them. This does not fit the experimental facts as now known.

Let me repeat that this doubtful matter does not in the least affect the fundamental points of the theory of surface films, which were so well established by Dr. Langmuir that years of further research have only consolidated his position on all the most important questions.

Dr. Langmuir suggests that too much is made of the 'tilt' of the molecules in the films. I must plead not guilty to much definite theorising in this direction, for we owe nearly all that has been done to Dr. Rideal and his school in Cambridge. But I am sure that if we could find out the tilt of the molecules, we should know much more about the detailed structure of these films than we actually do; and therefore, although I do not believe the recent theory of Lyons and Rideal, that the chains interlock at definite angles of tilt, is correct or even probable, I cannot but applaud them for having taken some cognisance of the possibility of definite angles of tilt determined by the form of the molecules. Dr. Langmuir thinks that the molecules are nearly as free in the films as in liquids, except for their being anchored to the water by their heads. This cannot, I think, be true of all states of the films; it may quite likely be nearly true of the liquid expanded films, but surely in the condensed films, both solid and liquid, there is not room enough for as much free motion of the molecules as occurs in liquids. In one kind of condensed film, where the area is greater than that of closely packed chains, I think that the packing of the heads and perhaps a small length of the chains close to the heads decides the *area* of the film, and the rest of the chains, being flexible, pack in as best they can into the space so determined above the heads; Rideal and Lyons seem to think that the heads determine the *tilt* of the molecules and that this tilt determines the area. These differences of opinion, we may hope, will be decided in course of time. N. K. ADAM.

Embryology and Evolution.

FOUR of Prof. MacBride's statements, in NATURE of Dec. 6, call for comment. "... no one has ever seen 'genes' in a chromosome." Genes cannot generally be seen, because in most organisms they are too small. In *Drosophila* more than 100, probably more than 1000, are contained in a chromosome about 1 μ in length. They are therefore invisible for exactly the same reasons as molecules. But the evidence for their existence is, to many minds, as cogent. Where the chromosomes are larger, as in monocotyledons, competent microscopists—for example, Belling, in NATURE of Jan. 11, 1930—claim to have seen genes. In a case where I (among others) postulated the absence of a gene in certain races of *Matthiola*, my friend Mr. Philp has since detected the absence of a trabant, which is normally present, from a certain chromosome. I shall be glad to show this visible gene to Prof. MacBride.

"... if Prof. Gates were a zoologist instead of being a botanist, he would know that the assumption that 'genes' have anything to do with evolution leads to results ... that can only be described as farcical". I should like to direct Prof. MacBride's attention to the droll fact that in a good many interspecific crosses various characters behave in a Mendelian manner, that is, are due to genes. This is so, for example, with the coat colour of *Cavia rufescens*, which, on crossing with the domestic guinea-pig, behaves as a recessive to the normal coat colour, but a dominant to the black. Hence there has been a change in a gene concerned in its production during the course of evolution. Scores of similar cases could be cited.

"All known chemical actions are inhibited by the accumulation of the products of the reaction. An 'autocatalytic' reaction, in which the products of the reaction accelerated it, must surely be a vitalistic one!" Autocatalytic reactions are common both in ordinary physical chemistry and in that of enzymes. Thus the acid produced by the hydrolysis of an ester may accelerate its further hydrolysis. As an example of an enzyme action, which for quite simple physico-chemical reasons proceeds with increasing velocity up to 75 per cent completion, I would refer Prof. MacBride to Table 7 of Bamann and Schmeller's[1] paper on liver lipase.

In view of such facts, Prof. MacBride's statement that "The term 'autocatalysis' is a piece of bluff invented by the late Prof. Loeb to cover up a hole in the argument in his book" would seem to be a wholly unfounded attack on a great man who can no longer defend himself. If Prof. MacBride would acquaint himself with the facts of chemistry and genetics, he might be somewhat more careful in his criticism of those who attempt to analyse the phenomena of life. He might also cease to ask the question propounded by him in NATURE of Oct. 25, "whether the organs of the adult exist in the egg preformed in miniature and development consists essentially in an unfolding and growing bigger of these rudiments, or whether the egg is at first undifferentiated material which from unknown causes afterwards becomes more and more complicated and development is consequently an 'epigenesis'". The formation of bone in the embryo chick was shown by Fell and Robison[2] to be due to the action of the enzyme phosphatase, which is neither a miniature bone nor an unknown cause. But so long as he does not take cognisance of recent developments in science, Prof. MacBride will no doubt remain a convinced vitalist.

Ravens Flying Upside Down.

BIRDS frequently perform strange antics in the air, both during courtship and at other times, and the air acrobatics of the raven have long been known. Thus Morris describes him as "performing various circling evolutions and frolicsome somersets in view of his mate". Yarrell, a better observer, says that in courtship the raven "turns over sideways on his back as he flies, shooting in that position in front of his mate". More recently, in 1917 if my memory serves me, the trick of flying upside down was referred to in a well-informed article on ravens which appeared in the *Times*.

Watching birds has long been a hobby of mine, and I once had the good fortune to see a raven flying on his back. The sight was extraordinary and unforgettable, but at the time I did not realise that I had witnessed

something very unusual in the behaviour of the raven, and unfortunately I made no note. Now, however, after the lapse of many years, it has been suggested to me that the facts are worth recording.

The observation was made in July 1917, when I was staying in Patterdale. One morning, between nine and ten o'clock, I was standing in front of Patterdale Hotel watching a pair of ravens flying across the Dale from Place Fell towards the wooded heights above Patterdale Hall. They passed by me rather low down and within about 200 yards. It was a clear, bright morning, and the sun being behind me the observing conditions were favourable. I was using an excellent pair of field-glasses, magnifying eight times, and with a field of about 5°. The two birds were flying close alongside each other, as is the habit of ravens. As they were passing by, the one nearer to me suddenly, and without any warning action, rolled over sideways and after falling in a confused fashion ended on his back, some five or six feet below his mate. In this position, and without losing horizontal speed, he continued flying; or to describe more precisely what I saw, he remained on his back, flapped his wings, and travelled along in what appeared to be level flight. He kept pace with his mate, who continued stolidly on her way entirely unconcerned by the antics of her partner down below. After flying upside down for a considerable distance, the raven rolled over again and got himself right side up; not without a fluster of wings and loss of height. By this time the birds were a good deal farther off and observation had become more difficult, but before they finally passed out of sight I noticed that they were once more flying side by side, as a pair of self-respecting ravens should do.

It was not easy to estimate the distance the raven flew upside down. Anyone who has had to do with the range-finding of aircraft, as I had to do during the War, will appreciate the difficulty of estimating, even roughly, the distance travelled by a flying bird. However, doing the best I could, I judged the distance the raven flew while he was upside down to be not less than 100 yards and very possibly a good deal more. That, at all events, was the judgment of the observer at the time and on the spot.

Some years later I began to wonder how the wings of a bird would work, if at all, when the bird was on its back; and whether, in the absence of aid from the flapping wings, the kinetic energy acquired in tumbling downwards would have sufficed to carry the raven on a level course over the observed distance. But such speculations as these do not affect what I saw, and the sight has remained vividly present in my mind from that day to this.

Masking of Spike-disease Symptoms in *Santalum album* (Linn.).

DURING the course of disease transmission studies, it was found that certain stocks for long periods did not exhibit the characteristic symptoms of the disease, and were therefore believed to represent disease-resistant varieties. The leaf tissue from such operated and disease-resistant varieties was found non-infective as shown by transmission experiments conducted with the leaf on susceptible stocks. Two such plants on being accidentally injured—in one case by a borer, and by wind in the other, both involving the removal of much foliage—exhibited the characteristic symptoms during the course of 15 days after the accident, with sprouting of the dormant buds. This suggested the possibility of accelerating the manifestation of disease symptoms by defoliation and by light pruning, which has met with great success. Foliage tends to inhibit the external manifestation of the disease symptoms. In one instance the infected stock remained apparently healthy for 417 days and more than doubled its girth and size during this period; but on light pruning and defoliation the stock exhibited the symptoms during the course of 16 days, with bursting of the dormant buds. A study of the physiological changes in the composition and reaction of the cell sap induced by defoliation should reveal the true cause of this remarkable phenomenon.

In diseased forest areas, therefore, external appearance of sandal is not the true criterion of its freedom from infection, which, if dormant, manifests itself on pruning the plant. This curious masking of symptoms in the case of sandal appears to be influenced by intense sunshine, and temperature. During this masked period the virus appears to be localised in certain tissues (phloem) of the plant, where it multiplies and exists in a highly virulent form.

The Designation of Women Biologists.

MANY years ago, Dr. Eigenmann, of the University of Indiana, finding certain small fresh-water fishes of South America very perplexing, decided to turn them over to one of his most capable students, Miss Marion Durbin. In due course of time Miss Durbin published a new genus and twelve new species of Tetragonopterid Characins, small fishes of a type which has since become very popular in parlour aquaria. Miss Durbin married Dr. Max Ellis, and papers on South American fishes, with new species, were afterwards written by each. As the species are usually cited, they are credited to Ellis, and the reader may or may not know that if they belong to a certain family they are of Max Ellis, if of another they were described by the former Miss Durbin. The first initial being the same in both cases, it is necessary to cite two initials to indicate which is which. In 1921 some new South American birds were published by G. K. Cherrie and Mrs. E. M. B. Reichenberger. There has just appeared an admirable revision of the birds of Matto Grosso, by Mrs. Naumburg. But Mrs. Naumburg is identical with the former Mrs. Reichenberger.

These examples suggest that, in view of the constantly increasing number of taxonomic papers by women, and the confusion which must result from the customary method of designating them, it would be an advantage to all concerned if, for the purposes of publication and citation, the maiden name were used without any change. It would always be possible to add the married name, as "By Mary Smith (Mrs. Wm. Jones)". Should this reform be supported by councils of societies and editors of journals, it is probable that little or no opposition would be met from the authors themselves. There is at least one well-known case of a woman author of taxonomic papers retaining her maiden name, though married.

Transmission of Infantile Kala-azar.

WITH reference to Drs. Adler and Theodor's note entitled "Infection of *Phlebotomus perniciosus* Newstead with *Leishmania infantum*", published in NATURE of Sept. 20, I would like to add that the insect concerned has not as yet been recognised as a distinct species, but only as a variety of *Phlebotomus major*

Ann. Mr. E. Brunetti [1] (1912) remarks in this connexion as follows: *P. major* var. *perniciosus* Newstead, "A form described by Newstead as a distinct species from Malta is, according to Dr. Annandale, only a variety of *P. major*, an opinion in which I am inclined to concur, there being no difference in either the venation or the male genitalia". Sinton [2] (1928) supports the same view.

S. MUKERJI
(Entomologist, Ancillary Inquiry into the Transmission of Kala-azar).

[2] Sinton, J. A., *Ind. Jour. Med. Res.*, 16, 2, pp. 303-305; 1928.

THE Editor of NATURE has kindly permitted me to see Dr. Mukerji's letter, and I am glad to have the opportunity of replying to it.

Several investigators have recognised that *Phlebotomus major* and *P. perniciosus* are closely related. França and Parrot (1921) named the latter sandfly *P. major* var. *perniciosus*. It is, however, certain in the light of recent investigations that *P. major* and *P. perniciosus* are distinct species. The males can easily be distinguished. They have a similar pattern of external genitalia common to all the males of the *major* group, but they show constant differences in important details.[1] The females can also be distinguished, though not so readily as the males. This problem is discussed in several papers which will be published shortly.

It cannot be emphasised too strongly that it is important to distinguish between closely related species of *Phlebotomus*, for these often show striking differences in their bionomics and distribution, and they may also differ in their capacity for transmitting disease. S. ADLER.

Leaf-Curl in Cotton.

IN an interesting letter (NATURE, May 3, 1930, p. 672) Mr. Kirkpatrick states that in the Gezira area (Sudan) an undetermined species of Aleurodidæ causes leaf-crinkle. In the Punjab (N.W. India) *Bemisia gossypiperda*, Misra and Lamba (Aleurodidæ), has been under observation during the last two years. This insect is present in enormous numbers but is not known to cause any deformation of the attacked leaves. Even in cages under conditions of a pure infestation of *B. gossypiperda* leaves literally covered on the under side with all the stages of the pest—eggs, nymphs, pupæ, and adults—remain quite flat and normal, and do not show curling, wrinkling, or crinkling. On the other hand, *Empoasca devastans* (Jassidæ) definitely causes leaf-crinkle.

From the sentence quoted by Mr. Kirkpatrick from "Cotton in Africa" (NATURE, Feb. 22, 1930, pp. 291-92), and from his own statement that "leaf-curl of cotton . . . is transmitted mainly, if not entirely, by . . . Aleurodidæ . . .", one is led to think that the disease is due to a causal agent which is carried either by a jassid or a white-fly. Has this been fully established?

In the Punjab we have had under observation several species of white-flies on several different hosts—for example, citrus, castor, sugar-cane, cotton, etc.—but none of these white-flies causes any malformation of the attacked leaves. M. AFZAL HUSAIN.

Living Ostracods in the Rectum of a Frog.

QUITE recently I received a communication from Mr. J. Omer-Cooper in the course of which he said: "When examining the contents of a frog's rectum yesterday in the course of our lab. work I noticed several living Ostracods. The frog had been kept for some time in a small aquarium which contains a good many ostracods. I have pickled up some of the contents of the rectum and also some of the ostracods from the aquarium. . . . The frog was chloroformed, well washed under the tap and dissected in normal salt solution. There is no chance that accidental contamination of the preparation can have taken place."

I examined both lots of ostracods and find that the two agree. Actually there was only one species present and that was *Pionocypris vidua* O. F. Müller, a very common ostracod. The observation is of interest as it gives a means of distribution of this ostracod, and the distribution of freshwater Entomostraca generally is a problem that requires a considerable amount of investigation.

There is, however, another aspect to the problem. The species in question is easily cultivated and reproduces parthenogenetically. Pure cultures can be obtained. If these are capable of passing through the intestines of various animals they may furnish a method of investigating certain changes that are going on there, both pathological and otherwise.

Prof. H. B. Dixon.

THE news of the sudden and unexpected passing of Prof. Harold B. Dixon has just reached me, bringing with it the shock of personal loss. As one of the oldest of his Manchester students, space may perhaps be granted me for a few words of personal tribute.

I saw Prof. Dixon last when I was in Manchester in 1925. I called at his house rather late in the evening and found him busily engaged with a tableful of papers, working out calculations in connexion with his latest researches on gaseous combustion. We talked about his work and exchanged news of his old students until I missed the last tram into Manchester.

It was not until quite recently that I wrote to tell him of my doings since that meeting, and by return mail I received a charming letter from him, enclosing a page from his diary, closely packed with a week's engagements, while gently chaffing me on my partial 'retirement' in Bangalore. It was the last example of his method of the *oratio obliqua* so well known to his students. Like all of these, I owe him unmeasured gratitude for shrewd and wise advice, and effective help, at critical junctures. His careful watchfulness over our welfare was not always realised until revealed by later happenings.

Prof. Dixon was a splendid example of the scientific research spirit at its best, combined with an active and broad interest in human affairs. It was a privilege to know him well and to come under the stimulus of his inspiration. GILBERT J. FOWLER.

The Machinery of the Earth.*

By Prof. J. W. GREGORY, F.R.S.

A DEFINITION of the word "machine" given in "The New English Dictionary" is "a combination of parts moving mechanically, as contrasted with a being having life, consciousness and will". According to that definition, the whole earth may be regarded as a machine, as it consists of various parts with differential movements, and it is moving in mechanical obedience to the forces of the universe and without any impulse or free will of its own. The study of the primary machinery of the earth involves consideration of its construction and of those movements of its parts which control its main function—the preparation and maintenance of its surface as the home of man.

THE STRUCTURE OF THE EARTH.

The geological method—the interpretation of the direct contemporary evidence of the rocks—has the drawback that it can only be applied directly to a thin layer, which is about one five-hundredth of the radius of the earth; and this restriction is the more regrettable as the material of the interior is different from that of the surface crust. The extent of this difference was revealed by Sir Isaac Newton, who calculated that the specific gravity of the earth is between 5 and 6. The figure generally accepted is 5·53.

Ordinary rocks vary in specific gravity between the 1·8 of clay, and 2·2 of sandstone, and 3·0 of basalt. The average cannot be more than about 2·5. For the whole rocky crust or lithosphere, which includes a great thickness of the deeper basic igneous rocks, the average specific gravity is taken by Tyrrell as 2·7. Hence the earth as a whole is composed of material more than twice as heavy as that of the crust. The internal mass is therefore appropriately named the barysphere, and a large amount of it must have a specific gravity four times as high as that of the rocks of the upper crust. It has been suggested that the matter in the interior owes its density to compression; but that view has been abandoned, and the high specific gravity of the interior is attributed to the segregation there of a large proportion of metals.

The high specific gravity of the earth can be accounted for by a metallic core with the specific gravity of about 8 to 10, or, perhaps in part, as much as 12. The material is probably mainly metallic iron alloyed with nickel, and containing smaller proportions of other metals and various silicates.

The composition of the barysphere is revealed by several lines of evidence. We may expect the earth to consist of the same materials as other heavenly bodies; and the most positive information as to the extra-terrestrial material is given by samples which fall upon the earth from outer space. They are known as meteorites and are most familiar to us as shooting stars. Their numbers are enormous. Any quick-sighted observer on a dark cloudless night can see about seven in the hour. Hence from 10 to 20 millions enter the earth's atmosphere every day. The meteorites are shattered into fragments, which fall in lumps or dust upon the surface. They are divided into two main classes. The iron meteorites or siderites consist of metallic iron with from 3 to 41 per cent and usually from 7 to 15 per cent of nickel and small proportions of other metals and some silicates. The second class are the aerolites or stony meteorites, which consist mainly of silicates and of mineral species, especially olivine and enstatite, common in the basic rocks of the earth's crust. A small intermediate group, the stony-iron meteorites or siderolites, consists of nickel-iron and silicates.

The proportion of the iron to the stony meteorites according to Sir Lazarus Fletcher's list of the meteorites in the British Museum in 1904 was 13·7 to 1. Dr. Prior's British Museum Catalogue of Meteorites (1923) includes all those known up to 1922 and has rendered practicable a more complete estimate. According to the records in that catalogue nickel-iron is twenty-one times more abundant in meteorites than stony material. Hence, if the earth represents a fair average of the material of the universe as revealed by meteorites, its metallic barysphere would have twenty-one times the bulk of the stony crust, which would be about 140 miles thick.

The relative thinness of the stony crust is confirmed by radioactivity. The earth's radioactive power is surprisingly weak. As determined by Lord Rayleigh, it can be accounted for if all the radioactive constituents are confined to a depth of about 45 miles. The material below that shell is practically non-radioactive. The iron meteorites are also non-radioactive. This evidence indicates that the earth's core is composed of nickel-iron.

This conclusion was originally advanced by J. Milne from the study of earthquakes. He found that earthquake waves which in their course go deeper than 30 miles undergo marked acceleration, owing to their entry into a highly elastic material which Milne called 'geïte', as it is the rock that forms the bulk of the earth; and he concluded that it consists mainly of nickel-iron. Subsequent research has confirmed this conclusion. The earth consists of an outer stony shell—the earth's crust or lithosphere—which is separated by a fairly sharp surface from the underlying barysphere. This inner mass, being denser, more elastic, and non-radioactive, is probably a mass of nickel-iron, like the iron meteorites. That the core of this mass is different in constitution from the rest was shown, also from earthquake evidence, by R. D. Oldham. He found that earthquake waves of distortion do not pass through the central region of the earth. Within the elastic barysphere is a centrosphere, which transmits waves of compression but not waves of distortion. It is therefore either a liquid or a gas.

An earthquake sends out waves of three kinds from its centre of origin. Two of the sets of waves are small vibrations or tremors that go through the

* From the seventeenth Thomas Hawksley Lecture of the Institution of Mechanical Engineers, delivered on Nov. 7.

earth; the third set are large waves that travel along the surface and may cause widespread devastation. All three kinds of wave are recorded on seismographs at a suitable distance.

The simple earthquake seismogram includes records of the three kinds of waves; it begins with small jerks made by the first tremors, which are waves of compression. They are known as the *P*-waves, *P* standing for primary, as they arrive first; but the late Prof. Turner suggested the name of push-waves as they are pressure waves. The second set are the *S*-waves or secondary waves, which are due to vibrations at right-angles to the path of the earthquake. They are waves of distortion. Prof. Turner called them the shake-waves. They are followed by the large waves or *L*-waves.

The first push- and shake-waves travel at the speed with which such waves travel through granite; hence they must have passed through a layer of the earth's crust composed of a rock like granite.

Farther from the centre the seismogram is more complex, as two sets of push-waves and two of shake-waves may arrive before the large waves. Still farther away there may be three sets of push-waves and three of shake-waves. The P_{g} or shallow push-waves have a velocity of 3¼ miles per second, which is that of such waves through granite. The second set of push-waves (*PP* or P_{x} waves) have a velocity of 4 miles per second, which is that of such waves in diorite; the third set of push-waves (P_{n}) have the velocity of 4¾ miles per second, which is that in such a highly basic rock as dunite.

Accordingly it appears that below the surface is a layer of rock like granite; beneath it occurs diorite, as suggested by Prof. Holmes; and lower still is a more basic rock, which transmits the push-waves at 4¾ miles per second.

Farther from the origin of the earthquake four out of these six sets of waves are not recognised and only the P_{n} and S_{n} waves and the main waves leave their record on the seismogram.

The P_{n} and S_{n} waves both traverse the geïte until they reach the depth of 1800 miles. A wave going to that depth, emerges at the surface at a distance of 103° from its origin; between that distance and 144°, the push- and shake-waves are not recorded. So an earthquake under the north pole would be felt by its push- and shake-waves so far as 13° S. of the equator, in say southern Peru; farther south there would be no record of them before reaching the latitude of Cape Horn; but farther south again the push-waves would disturb the surface so far as the south pole. The shake-waves, however, would not be felt anywhere south of Peru.

This suppression of the shake-waves around the antipodes to the place of origin of an earthquake was first recognised and explained by R. D. Oldham. He pointed out that as only the waves of compression reach the antipodes, the earth's central core must consist of material which transmits waves of compression but not waves of distortion. It must therefore be liquid or gaseous. That it is liquid is shown by the yielding of the earth to tidal strain, which indicates a less rigid earth than earthquake observations; and Dr. H. Jeffreys has shown that the contradiction between this evidence disappears if a liquid centrosphere occupies half the diameter of the earth.

According to Oldham and Knott, the liquid core is a fifth of the radius or $\frac{1}{125}$th of the mass of the earth; but according to Dr. H. Jeffreys' estimate it is half the radius, or an eighth of the mass of the earth. This huge centrosphere is doubtless a liquid mass of nickel-iron, which, owing to compression, has a specific gravity of 12.

Such, then, is the general structure of the earth-machine; it has a fluid centre, a thick metallic shell, the barysphere, and an outer rocky crust, the lithosphere.

As the earth is approximately spherical, we may regard it as a huge projectile, travelling at an enormous velocity through space, and consisting of an iron shell which, like those of modern artillery, is hardened with an alloy of nickel.

ORIGIN AND HISTORY OF THE EARTH.

The separation of the barysphere and lithosphere is the natural result of their difference in specific gravity. The lithosphere consists of light silicates and earthy materials which floated to the surface out of the heavy metallic mass, as the earthy impurities in iron-ore float to the top as slag when the ore is smelted in a furnace. The rocky crust may therefore be regarded as a slag which has exuded from the metallic mass below.

Laplace's long accepted nebular theory of the origin of the solar system is now generally discredited; and the earth is regarded as either a mass torn out of the sun by the attraction of a passing star, or as due to the aggregation of a swarm of meteorites, and mainly of those which, having a planetary orbit, are regarded as infinitesimally small planets and are known as planetismals.

The meteoritic theory of Lockyer and the planetismal theory of Chamberlin and Moulton are both out of favour in Great Britain; but they have to the geologist the advantage that they do not start the earth as a fragment of a body with, according to C. E. St. John, the temperature of 29,000,000° C. For the oldest and most deep-seated of the known rocks in the earth's crust show no evidence of transcendent temperatures.

Either the earth never experienced the supreme temperatures of the sun or hotter stars, measured by millions of degrees, or it had cooled down to about 5000° F. before the formation of the oldest known part of the crust.

The earth clearly passed through a stage in which it was so hot that it was plastic and behaved as a fluid body. One relic of this early stage is the high temperature of the earth's interior, as known from the uncomfortable heat of deep mines and the boiling water of deep-seated springs. The standard rise of temperature underground in Europe is 1° F. for every 53 or 58 feet of descent.

If that rate continued, the temperature 5 miles deep would be above 500° F. and at the earth's centre, 3950 miles deep, would be nearly 400,000° F. There is no geological evidence for such a tem-

perature within the earth. None of its minerals imply temperatures higher than the 2500° F. of sillimanite, or the 3100° F. of cristobalite, or the 3450° F. of some species of olivine. There is no geological evidence that the central hot mass or thermosphere has a temperature higher than a few thousand degrees. The internal heat was not too high to prevent the formation of a solid non-conducting crust, which soon became so thick as to prevent the thermosphere having any material influence on climate. The oldest interpretable fossils indicate that at the beginning of geological time the climate of the earth was about as warm as in modern times. Evidence of this surprising fact is given by the existence at about the time of the oldest fossiliferous rocks of glaciers in the Yangtze-kiang Valley, and of glaciers that nearly reached the tropics in South Australia. Those glaciers do not imply that all the earth had then a colder climate; but they do prove that the conditions were not tropical over the whole of the earth. Judging from the marine organisms nearest in date to these early glacial deposits, the mean climate of the earth was similar to that of to-day.

Climate has undergone marked local variations. Sometimes it was more uniform over the earth and at others the extremes were greater, after mountain uplifts had increased the local differences.

Even allowing for such changes and for those due to different distributions of land and sea, the meteorological agents have been remarkably uniform. In rocks of all ages the imprints of the raindrops are of about the same size. The sand grains spread over the deserts or heaped in sand dunes, and the ripples on 'the sands of time' have been always approximately equal; and the particles of volcanic dust and tuff also show that the ejecta of ancient and modern volcanoes have been scattered by volcanic explosions and winds of similar power.

This climatic uniformity since the Cambrian period indicates that the earth's crust had by then acquired approximately its present thickness and strength. Before that date it must have been thinner and weaker, as is proved by the universally tilted condition of the primeval (Pampalozoic) rocks. The sedimentary rocks of the crust were deposited in horizontal layers; most of them have been tilted. The younger rocks generally have a slight dip except near fold-mountain chains, which are due to the crust having been squeezed into a smaller space, and having accommodated itself to this compression by folding. In modern rocks violent lateral compression is limited to relatively narrow belts along the younger fold-mountain chains.

As the older rocks of the crust are steeply tilted in all parts of the earth, the pressure that disturbed them was then universal. The crust was undergoing contraction to an extent which threw all that is known of it into folds, for as the crust sank over the diminishing internal mass the whole of it was packed into a narrower space and was thereby thickened and strengthened.

The change from the thin, universally crumpled crust of the older primeval time to the thicker, stronger crust which yields to compression by package along narrow bands has led to a fundamental difference in geographical conditions. Land and water were re-distributed and this change had a great effect on local climates.

When the crust was weak, its buckling would have produced many shallow basins and domes, so that water was distributed in land-locked seas, scattered widely over the surface. The total sea surface was apparently much less than at present, for the commonest rocks of the latter part of the primeval era are reddish sandstones and layers of red shale, with wind-rolled sand grains and pebbles polished and faceted by wind-blown dust.

The powerful effects of the wind and the prevalent desert conditions may have been due in part to the absence of turf, which binds the sand and prevents its grains being constantly rolled forward by the wind. The lack of land vegetation suggests that the environment was unfavourable for it. The extensive limestones in the primeval seas indicate that seaweeds were luxuriant. The failure of plants to grow well on land suggests that the conditions did not suit them. The absence of land vegetation until Silurian and Devonian times may have been due to climate. The prevalence of deserts in the upper Pampalozoic is evidence of a dry atmosphere, which would have been the natural result of a greater proportion of land to sea than in later geological epochs.

The growth of the seas involves an increase in the amount of water on the earth's surface. The possibility of this increase was discredited when the authoritative estimates of the age of the earth varied between ten million and a hundred million years. Annual additions to the surface water that would be negligible in a few million years become important when they accumulate for thousands of millions of years.

At one time it was held that all the water on the earth's surface is meteoric and has fallen as rain. But the evidence is convincing that much of the water of hot springs and deep mines and that given off by igneous rocks and volcanoes is of deep-seated origin. It is plutonic water which has worked its way to the surface. The amount discharged was probably greatest in early times when the crust was thinner and more often fractured. The transfer of deep-seated water from the interior to the surface during geological time must have added largely to the volume of the seas. According to Prof. Schuchert the earth's surface water may have increased by 25 per cent since the beginning of the Cambrian period. Though data for a quantitative determination are inadequate, the evidence is in favour of the seas of the earlier days having been shallower and less extensive.

Hence, although the earth's crust had early become sufficiently thick to cut off the surface from any material contribution from the internal heat, yet the shrinkage of the interior so frequently fractured the crust that plutonic water rising through the fissures has continually widened the seas and thus helped in the better nourishment of the land.

THE EARTH IN MOTION.

The earth is not only a complex structure built up of several distinct parts, but also it is in motion at a terrific speed. It is charging through space, with the rest of the solar system, at the rate of 750 miles a minute; it travels along its orbit around the sun at more than 1000 miles a minute; and its rotation around its axis gives any place on the equator an additional movement of more than 1000 miles an hour. The fact that the earth holds together in spite of such movements shows that it is strongly constructed: but it is sufficiently plastic, owing to its hot interior, to be automatically moulded into a spheroid, or more correctly, into a geoid. It is approximately an oblate spheroid owing to the moulding force of its rotation.

The rotation has not been uniform. Owing to tidal friction it is slowly losing speed and the day lengthening. According to Sir George Darwin and Dr. H. Jeffreys, the earth's day was at one time only five hours long. Changes in the shape have also affected its rate. For example, the polar regions have been raised and lowered to an extent that would have affected the earth's ellipticity as shown by the widespread occurrence of raised beaches in both the polar regions. These beaches are so regular and horizontal that they have been attributed to the so-called 'eustatic' movements or world-wide variations of sea-level. But that view is improbable, as the raised beaches, which are conspicuous in Scotland, occur at a lower level or are absent from most of England.

A change in the earth's rate of rotation would produce circumpolar beaches, for its slackening would lower the sea in the tropics and raise it in the polar regions. The distribution of the raised beaches is, however, probably due to the alternate subsidence and upheaval of the polar areas; and if both of them had sagged simultaneously the earth's ellipticity would have been increased and therefore also its rate of rotation.

The earth revolves like a badly made and badly mounted fly-wheel, and its wobbling causes some shifting in the position of the poles, as proved by the variation of latitude. The movement of the poles that has been actually observed is small, and has been attributed to meteorological factors, which Dr. Jeffreys has shown to be insufficient. The deformation of the earth by crustal changes is the more probable cause. Any extensive migration of the poles has been declared impossible, since a body with so heavy a load on its circumference as the earth's equatorial bulge could undergo but minor oscillation of its axis. That the wandering of the poles has been within narrow limits is consistent with the geological evidence; for the distribution of animal life has been along zones that were in general parallel to the present climatic zones.

The changes in shape of the earth have, however, had an important influence in other respects. The earth cannot be deformed beyond a limited amount or it would become unstable and ultimately fly to pieces. But with the wonderful automatic adjustments of the earth, as soon as deformation renders the crust unstable, stability is restored by movements by which the approximately spheroidal form is recovered. The convulsions during this process lead to changes in the crust that are indispensable for its primary service as the home of man. The lot of man is dependent on the earth's movements in space and on its power of self-adjustment to changing conditions, both internal and external. The combined rotation and revolution determine the weather and weather-changes in all parts of the earth, and thus control the habitability of the earth. The movements within the crust, which depend on its adjustment to the shrinking interior, provide for our many and fastidious needs.

The earth's atmosphere is apparently fickle and liable to great changes in composition, but the limits of its variation must be narrow. Its maintenance at the special composition breathed by animals, and that protects the earth from undue changes of temperature, is one of the beneficent functions of the sea. The efficiency of the atmosphere depends on its content of carbon dioxide, which is affected by many agencies. The sea acts as the great regulator of the atmosphere, and counteracts the disturbing factors; if too much carbon dioxide is taken from the air the bicarbonates in the water are dissociated and the sea breathes it forth until the standard proportion is restored. If volcanic activity or forest fires add an injurious amount to the air, the sea absorbs the excess and retains it as bicarbonates. The atmosphere is thus maintained at the special composition necessary for human respiration.

Man requires dry land that has been drained and left available for his occupation, and it would be of no use unless most of its surface were sloping. The land is constantly being lowered by wind and rain, and would in time be planed so level that the rain water would lie upon it and be removed only by the slow, chilling process of evaporation. But, thanks to the interaction of the crust and the shrinking interior, the surface is being lowered in some places and upheaved in others. The instability of the crust, which we deplore when an earthquake devastates a province or slays a hundred thousand people, renews the slopes on which the habitability of the earth ultimately depends.

The crustal movements by tilting the surface produce slopes which are essential for the flow of water and the formation of the grassy steppes where have evolved many of the animals most helpful to man, including those that supply wool and hair for clothing, meat and milk, and serve as beasts of burden.

Man also requires a soil that will produce the foods necessary for his nourishment; and soil is a delicate instrument that is easily exhausted and rendered infertile. The flow of water, though indispensable, charges the soil heavily for its service. Water is the most active of general solvents and removes in solution enormous quantities of the constituents essential to plant growth.

This process would in time leave only insoluble materials, and the soils would be barren and useless.

The earth is saved from this fate by the re-fertilisation of the soils from the primary rocks of the interior, which are rich in lime, alkalis, and phosphorus. Movements within the earth upraise igneous rocks to form highlands and mountains, and their constituents are washed down the slopes and renew the fertility of the lowland plains.

The tilting of the rocks on the surface in consequence of the internal shrinkage makes another essential contribution to the economy of Nature. Many of the most useful minerals lie in the old rocks, and if they were still horizontal the minerals would be so deeply buried that their discovery and economic working would be impracticable. But as the rocks have been tilted and folded the mineral seams are exposed on the surface, where they are easily found and can be profitably mined.

Hence the interaction of the different parts of the earth machine has rendered possible the evolution of man and still controls his destiny; for it keeps the earth's surface drained and habitable, it distributes the seas so that the land is supplied with rain and fresh water; it maintains the constituents of the air at the balance required in the breath of life, and it raises from the interior the minerals that renew the fertility of the soil and provide the mechanical engineer with the materials that have rendered possible the development of modern civilisation.

The Adequacy of Human Dietaries.

THE importance of the food supply in the preservation of normal health and well-being is generally recognised among scientific observers, but the necessity for a scientific selection of the food, in addition to that due to the dictates of appetite, is not always realised by many classes of the population. Dietary surveys, carefully performed, will indicate the adequacy, both quantitative and qualitative, of popular diets, in terms of accepted standards: when estimates of the cost of the diets are also made, data are available as to the minimum cost of an adequate food supply under different conditions. At the same time, encouragement may be given to education on the planning of adequate diets at minimum expense, especially if the surveys indicate that many dietaries are not only inadequate but also expensive.

J. B. Orr and M. L. Clark (*Lancet*, vol. 2, p. 594; 1930) have recently completed a survey of 607 families in seven cities and towns in Scotland. The information was collected from the housewives and is considered to be fairly reliable. For the calculation of the composition and energy value of the diets, Sherman's and Plimmer's tables were used. These tables allow for inedible material in the food purchased, but not for waste, for which 10 per cent should probably be deducted from the figures given for food consumption. Allowance must also be made for the fact that the food requirements of women and children differ from those of men; it is customary to express their requirements as a fraction of that of an adult man, taken as equal to 1, so that the 'man-value' of the diet of each family was calculated, using Cathcart's table. No account, however, was taken of the occupation of the adults. The mean man-value for each family was 4·86; the calorie consumption per man per day was 3609 cal., composed of 108 gm. protein, 574 gm. carbohydrate, and 86 gm. fat. The consumption in individual households varied widely from the mean, as shown by coefficients of variation of 20-30 per cent. Cases of insufficient caloric consumption were, however, relatively few; a larger number showed an intake of 4000 cal. per man per day or more, indicating either an unnecessarily high consumption or excessive waste. The average is slightly higher than that found in previous studies in Great Britain, but lower than in those carried out in other countries. Protein accounted for 12·3 per cent, carbohydrate for 65·5 per cent, and fat for 22·2 per cent of the calories.

A less satisfactory state of affairs was disclosed when the protein, calcium, phosphorus, and iron intakes were determined. The protein consumption was below the standard in about two-fifths of the families. The average figures found for the minerals were: calcium 0·86 gm., phosphorus 1·70 gm., and iron 0·0143 gm. per man per day. The figures for calcium and phosphorus are slightly above Sherman's estimates of an adequate intake, that for iron slightly below. About one-quarter of the families were receiving too little calcium and phosphorus, and nearly two-thirds too little iron.

Cathcart's figures for man-value are based on maintenance requirements; when a more stringent standard (Hawley's) was employed, which makes allowance for the fact that growing children require relatively more of certain constituents than adults, a larger number of families showed deficiencies in their intake of protein or minerals. In fact, most of the diets appeared incapable of supporting the optimum rate of growth.

The results of the survey probably explain, at any rate in part, the results obained by G. Leighton and M. L. Clark when extra milk was added to the diet of school children (*B.M.J.*, vol. 1, p. 23; 1929). It was found then that the addition of about a pint of extra milk daily to the diet was followed by an increase in the growth rate, indicated by increased weight and height as compared with the controls. Separated was as good as whole milk, but biscuits had no such effect; separated milk is a good source of protein and minerals, and to these a part at any rate of the good effect can be ascribed. Orr and Clark conclude that the dietaries of urban households can be considerably improved by the addition of milk to supply protein, calcium, and phosphorus, and of green vegetables to supply calcium and iron; both would also supply any vitamins deficient in a carbohydrate-rich diet.

F. M. Williams and J. E. Lockwood have carried out a similar survey among farm and village

families in Central New York, with the addition that the costs of the diets were also worked out (*Bulletin* 502, April 1930, Cornell University Agricultural Experiment Station, Ithaca, N.Y., U.S.A.). The survey in each family covered a period of four weeks and both bought and home-grown food was included, the cost of the latter being credited at current average wholesale prices. The standards used were similar to those employed by Orr and Clark, though the table for calculating the 'man-value' of a family with respect to energy requirements was not quite the same. In addition, an 'adequate food cost unit' was employed; this was obtained by taking the annual retail value of a diet supplying 3400 calories daily, a 'man's' requirements, as equal to unity, and expressing the cost of other diets as a fraction thereof. The adequate food cost scale was found to diverge slightly from the energy scale, especially in the case of children and when diets of low energy value were employed, since, for calories consumed, the cost of these is relatively high.

The analysis showed that 42 per cent of the village families and 64 per cent of the farm families were adequately fed. In many cases home-produced food made a substantial contribution to ensuring the adequacy of the diet and accounted for a considerable part of the retail value of the food consumed. In the inadequately fed families, it appeared that poor food selection rather than poverty was the cause of the poorness of the diet: the deficiency was most marked in the minerals, less so in the protein and calorie consumption. As in Orr and Clark's study, over-consumption was observed in a number of families.

The result of the study indicates the importance of proper selection of the food, and the addition to income represented by a supply of home-grown produce.

News and Views.

WHEN the Expiring Laws (Continuance) Bill came before the House of Lords on Dec. 15, Viscount Hailsham's amendment, which provided for the continuance of the Dyestuffs (Import Regulation) Act, 1920, until Dec. 31, 1931, was carried by 87 votes to 14. Viscount Hailsham sketched once again the circumstances attending the birth, decline, and revival of the industry in Great Britain. During the past ten years the progress made has been so remarkable that success appears to be the main argument used against the continuance of a protective measure. Although the Council of the Colour Users' Association expressed a majority opinion in favour of the lapse of the Act, the president of that Association holds the contrary view; any risk of undue exploitation in the matter of price is removed by the undertaking which the dye-makers have given. Lord Parmoor (Lord President of the Council) repeated the Government's view of the matter as involving conflict between dye-makers and dye-users. The dye-makers have been put into a position in which they can compete with imported dyes; they have built up a great industry, for which everyone is grateful, but the time has now come to make the change in the interests of the dye-user. The Earl of Crawford said that so far as research is concerned, this industry has been a triumph. Some of the most remarkable discoveries in organic science have been made by men working on dyestuffs. The industry is emphatically a key industry, is of great importance in defence, and is becoming the focus from which pharmaceutical progress radiates. The Marquess of Reading said that the matter is not one of free trade or protection; Lord Cowley claimed that the continuance of the Act would be a burden on the textile industry, a view which was challenged by Lord Newton, who showed how small is the cost of the dye contained in a suit of clothes. Lord Arnold, Paymaster-General, contended that the dye industry would not be injured. Hence the present situation, besides being of political interest, may lead to a comprehensive scientific examination of a scientific and industrial problem.

THE Slaughter of Animals Bill, which passed its second reading in the House of Commons on Dec. 12, would make compulsory in England the modern methods of slaughter already in vogue in Scotland, Holland, and elsewhere. This measure has been vigorously resisted for many years by the meat traders, but their opposition has now been withdrawn except as regards the inclusion of pigs. The questions at issue were mainly questions of fact which could be, and nearly all have been, settled by experiments and observation in a scientific way. In 1925 the meat inspectors of the City of London Corporation conducted trials on an extensive scale, and since then other trials of a scientific character have been carried out, notably that by Dryerre and Cameron of Edinburgh. It is to be regretted, therefore, that some members of Parliament attempted to deal with these matters of fact by means of disingenuous rhetoric. One member, for example, dramatically produced two skulls, as evidence of the relative merits of the poll-axe and the humane-killer; whereas the City of London meat inspectors had tested this point by observations on no fewer than 1745 animals. Again, Messrs. Marsh and Baxter circulated to every member a manifesto in which they alleged that the humane-killer causes 'blood-splash' in pigs, and quoted in support of this view veterinary opinions all dated 1923 or earlier; whereas in 1925 the City of London meat inspectors examined more than 700 shot pigs, and found that "in not one of them was splashing in the slightest degree observed". Humanitarians may learn a lesson from the rapid progress that has been made by the humane-slaughter movement in recent years. Most of its advocates have worked by patient insistence on verifiable facts, and its success has been far greater than that achieved by some other good causes in the promotion of which there has been recourse to exaggeration and rhetoric.

THE Pilgrim Trust, founded by Mr. Edward S. Harkness of New York, has made one of its first gifts to the Royal Institution. The Trustees have allocated

the sum of £16,000 to meet the deficiency on the fund, for reconstruction of the building in Albemarle Street. In informing the Institution of this grant, the Trustees state that in making it they had regard to the distinguished scientific services rendered to the whole community for more than a century by the Royal Institution, and to the approaching Faraday celebrations. They were also not unmindful that the founder of the Royal Institution, Count Rumford, was of American origin. The provision of funds to meet the cost of the extensive programme of reconstruction which was forced upon the Managers has been a matter of the greatest concern to them and to every friend of the Institution. It will be recalled that, following a series of alarming explosions in Albemarle Street more than two years ago, the condition of the historic lecture theatre from the point of view of fire risks was shown to be such that reconstruction could no longer be deferred. Plans conforming to modern standards of fire protection, including the provision of suitable exits from the theatre, proved to involve the rebuilding, not of the theatre itself alone, but also of a large part of the structure surrounding it. After the fullest consideration, the work was put in hand at an estimated cost of not less than £80,000; now, as it is rapidly approaching completion, the actual cost is found to be upwards of £90,000.

THE aim has been to raise the sum required for reconstruction without drawing upon the existing funds of the Royal Institution and thereby crippling the already inadequate provision for research. In this the Managers have been successful, and by special measures, and with the generous assistance of private individuals, and of industries which have benefited, indeed in certain cases have their origin in the scientific work at the Royal Institution, they have raised a large fund. This, with the addition of the £16,000 from the Pilgrim Trust, is now sufficient to meet practically the whole cost of the rebuilding. The Institution is thus enabled to enter upon the year of the forthcoming Faraday celebrations and to look forward to a continuance of its work free from immediate financial embarrassment. With the cost of the rebuilding provided for, the Managers are free to turn their attention to another pressing object, the endowment of research. Some progress has already been made towards the establishment of a fund for this purpose. In the coming year it is hoped to add considerably to this fund, and thereby to place the scientific work of the Royal Institution and the Davy Faraday Laboratory on a financial footing which accords with the requirements of modern research.

FOUNDED in 1881, the Society of Chemical Industry will next year celebrate its jubilee, chiefly by means of proceedings of a domestic character associated with the annual meeting, which will begin on July 13 and extend over the succeeding seven days. It is intended to confer the rare distinction of honorary membership of the Society on a small number of eminent foreign technologists. It is also intended to present inscribed plaques to the original members of the Society and to the prime wardens or masters of such livery companies of the City of London as have specially fostered the education or progress of applied science. In addition to the social engagements appropriate to such an occasion, there will be arranged exhibitions of apparatus and plant and visits to works typical of the manufactures of London. Two special publications are being prepared in honour of the jubilee. Dr. Stephen Miall, editor of *Chemistry and Industry*, is writing a comprehensive history of the chemical industry, whilst a special number of the Society's *Journal* will include reprints of the outstanding papers which have appeared during the fifty years of its existence. The progress of chemical industry and that of the Society itself will be outlined, and use will be made of the opportunity for biography. These publications will be available to the general public, for whose information and interest there are also being arranged a series of broadcast addresses and the distribution of authoritative articles dealing with the relation of chemistry to life and industry.

THE International Conference on Silicosis held at Johannesburg on Aug. 13–27 last has an interest quite apart from the valuable conclusions reached in its study of the medical aspects of this dangerous industrial disease. The Conference, which was summoned by the International Labour Office with the assistance of the Transvaal Chamber of Mines and the Government of the Union of South Africa, was the first held outside Europe under the auspices of the League of Nations, and was also the first experiment in co-operation between the International Labour Office and the scientific world. Delegates from Germany, Australia, Canada, Great Britain, Italy, Holland, the Union of South Africa, and the United States of America participated in the work of the Conference, which, in addition to the opportunity of exchanging views and comparing practice, enabled the delegates to obtain personal acquaintance with the achievements of the Miners' Phthisis Bureau of South Africa. An average of £1,000,000 per annum is spent by the mining industry of the Rand in medical care and compensation for silicosis, and Mr. Sampson, the Minister of Posts and Telegraphs, in opening the proceedings, stressed the value of international co-operation in combating this disease.

THE recommendations of the International Conference on Silicosis were adopted as a result of discussion upon reports presented upon three groups of problems: prevention, medical aspects, and compensation—the greater part of the sessions being devoted to the discussions in these groups. Among the recommendations of chief interest to scientific workers are those which urge the absolute necessity of scientific research, and particularly research designed to secure uniformity of terminology and of radiological technique. The collection of further information concerning the incidence and development of the disease and the study of methods of rehabilitation was urged, and the Conference requested the International Labour Office to publish periodically a bibliography on silicosis. The Conference sets a

precedent that might well be followed more widely in the co-ordination of scientific research on social and industrial subjects.

IN connexion with the International Conference for Phytopathology and Economic Entomology held in Holland in 1923, prizes were offered in 1928 for the best two memoirs concerning (1) investigations on rust diseases (Uredineæ) of cereals, and (2) investigations on the rôle played by insects or other invertebrates in the transmission or initiation of virus diseases in plants, the prizes being of the value of 1000 Swedish crowns (about £55) each. It is now announced that the prize for the most meritorious investigations on Rusts has been awarded to Mr. J. H. Craigie, Senior Plant Pathologist in Charge, Dominion Rust Research Laboratory, Winnipeg, Manitoba, Canada. Mycologists will recollect that it was Mr. Craigie who recently discovered the hitherto unknown and important function of the spermogonia of the rust fungi. The adjudicators have made no award in connexion with the subject of the second prize.

ONE of the most interesting developments in high voltage engineering is the use of a method by means of which cables are kept constantly impregnated with oil. As the temperature of the cables is continually altering owing to variations in the load, it is necessary to provide means so that when the cable is hot it is relieved of the excess oil caused by expansion due to temperature and when cold the oil is returned to it. For this purpose feeding tanks have to be supplied when the level of the cable is high and pressure tanks when the level is low. These cables seem to be opening up a new era in power transmission and they are being very closely studied. In the *G.E.C. Journal* (England) for November is published the second of a series of articles by E. H. Horley on the manufacture and testing of the accessories used in oil-filled cables. He points out that the length of the cable which can be supplied from one feeding tank is limited by the viscosity of the oil and the resistance the central channel in the cable offers to the flow of oil along it. The length of this section can be increased considerably by using a pressure tank to assist the feeding tank by taking in oil during the first period of the heating of the cable and sending it out during the first period of the cooling. This is done by constructing cylinders containing flexible walled cells made of corrugated nickel plates. The number of these cells corresponds to the amount of oil required to operate the section of the cable. To test a cell, it is subjected to 10,000 cycles of rarefaction and compression. The test is done automatically for a few days and nights, and is equivalent to several years of actual working. Every length of cable dispatched from the factory has a tank filled with oil under pressure connected with it.

As Italy has practically no coal resources, it has to import nearly all its own coal. Since the War, the price of coal in Italy has fluctuated between wide limits. At the present time it is about thirty shillings per ton. One of the objects of electrifying the railways in Italy was to utilise the water power available in the mountainous regions and thus reduce the importation of coal. Last year the saving effected in amount of imported coal required was about 20 per cent, and the average water power developed exceeded two million kilowatts. During the thirty years since electric traction first began to be used, much experience has been gained on the electric systems in use. G. Bianchi read a paper on this subject to the Institution of Electrical Engineers on Nov. 20. Up to 1916, 230 miles of the railways had been electrified on the three-phase system at 16 cycles. A drawback to this system was that it required exclusive generating stations fairly close together and so further electrifications after 1916 were carried out on the three-phase system at the standard industrial frequency of 45 cycles. The energy was converted into direct current of 3000 volts before reaching the motors of the locomotives, as this has the advantages of simplicity of the overhead contact line and great ease in speed regulation. It was originally intended to confine the 3000 volt d.c. system to the lines of southern Italy, but it has now been decided to carry out the electrification of the Florence-Rome and of the Milan-Bologna lines on this system. When this is done, there will extend from Milan to Naples an electric line which, traversing the peninsula from north to south, will carry the greatest part of the longitudinal traffic of the Italian railways. In order to meet the eventuality of a substation break-down which cannot be repaired in a short time, travelling sub-stations have been constructed. These travelling sub-stations have proved so useful, both from the technical and economic points of view, that it seems probable that they will come into continuous use.

IN two addresses to members of the Eugenics Society in association with the Psychology and Education Sections of the British Association at the Bristol meeting, Prof. R. J. A. Berry, Director of Medical Services in the Stoke Park Colony, Bristol, discussed the physical basis of mind and the diagnosis of mental deficiency. His addresses are summarised in the October number of the *Eugenics Review*. He points out that probably 80-90 per cent of primary mental deficiency is due to bad heredity. In mental defectives it is the pyramidal cells of the controlling supragranular cortex of the brain which are chiefly lacking, while those controlling the animal instincts of self-preservation and sex are often well developed. Mental defectives are usually more or less markedly microcephalic owing to the small development of the brain. Several striking cases were described, illustrating the various types of arrested mentality—the idiot, the imbecile, and the feeble-minded. The various physical and mental tests applied in determining the mental condition are also described. A feeble-minded woman thirty-two years of age may have the brain of a girl of six years and the mental capacity of one of eleven years, combined with bodily growth at the fourteen-year level and the sexual passion of an adult. Lack of control of the natural reactions is the inevitable result. Prof. Berry states that in Great Britain we are spending some £93 per head per annum on mental defectives, who frequently are allowed to reproduce their kind,

while we spend only £12 per head on the normal child. Thus does civilisation bring about its own downfall.

REFERRING to the correspondence under the heading of "Highest Recorded Shade Temperature", on p. 723 of NATURE for Nov. 8, Prof. A. J. Henry gives some further interesting particulars of the conditions under which a temperature of 134° F. was recorded at Greenland Ranch, Death Valley, California, on July 10, 1913. On the day in question there was a slow drift of air from the north, that is, from the high plateau of Nevada, which reaches a general elevation of 6000-8000 ft. On this bare continental plateau the temperature probably approached 100° F., in spite of the elevation. Death Valley itself lies below sea-level, and in its steep descent of several thousand feet from the Amargosa and Funeral Mountains the air was warmed dynamically to a most abnormal temperature. The extreme conditions occurred only in Death Valley, which is a long, narrow trough running north and south, while in other parts of California the day was not especially hot; but these considerations justify the acceptance of the record. Unfortunately, there is not sufficient information available in Great Britain to examine the Azizia record in similar detail, and Prof. Henry is still sceptical as to its reality.

INQUIRIES are often made by amateur naturalists as to how, without starting upon some intricate investigation, they may add new facts to the sum of knowledge. To such and to their advisers we commend an article in the November issue of *British Birds* on "Our Present Knowledge of the Breeding Biology of Birds", by the Rev. F. C. R. Jourdain. The author emphasises the lack of information which at present exists about the length of the incubation period in many common birds, and about that interesting and variable detail, the parts taken by the cock or hen or both in sitting upon the eggs and later in tending the young. The information given is of real value as a guide to the potential investigator, for not only does the article contain a list of the birds concerning which further observations are required, but also it states the form which the observations ought to take. Readers familiar with the immense amount of literature which has been devoted to the birds of the British Isles will be amazed at the number of blanks which occur in the records of incubation and fledgling periods of common birds.

IT is highly probable that in the future tidal power will be used extensively. In most industrial countries, however, the low cost of coal and the progress made in the technique of coal burning imposes a severe restriction on its development, except in a few very special cases. The main problem that has to be overcome is to find an economic way of getting a continuous supply of energy from a variable source. An experimental attempt is being made at the Avonmouth docks (NATURE, Oct. 4, p. 541), where the tidal range is about 30 feet; of this, about 10 feet cannot be used by the turbines and recourse is had to a steam accumulator which has been 'charged' by the tidal turbines. In *World Power* for November, two tidal projects in the Argentine are described, one at the mouth of the Descado River, and the other at the Gulf of San José. The Argentine has a difference between high and low tide levels sufficient to justify the consideration of a tidal scheme and a Government commission has reported favourably on it. In the Gulf of San José, the sea rises 15 feet in neap tides and about 26 feet in spring tides. By a special arrangement the turbines can be made to run in the same direction whether the tide is going out or coming in. It would be possible to have five hours' continuous operation out of every six.

A NEW high-tension power line, costing more than one million pounds sterling, between Toronto and the Paugan Falls electric generating station, a distance of 230 miles, has just been brought into operation by the Ontario Hydro-Electric Power Commission. The voltage of the transmission line is 220,000, which is the highest yet adopted in Canada. In transmitting 150,000 horse-power, the line is also believed to carry the greatest volume of electric energy. It is used to supplement supplies received from Niagara Falls, the station generators at which are now working in perfect synchronisation with those at Paugan Falls. The new line is carried on steel towers, 73 ft. in height, placed at distances apart of about one-fifth of a mile. It is the second of two service lines from Paugan Falls to Toronto. Both are of aluminium with a steel core, the external diameter being $1\frac{1}{8}$ inches. It is interesting to note that the route was planned with the aid of aerial photography. Located in the first instance from the best available maps, the route was photographed with oblique exposures, after which a definite line was selected. This was then re-flown and vertical photographs taken, from which a mosaic map was made for detailed study and the selection of tower sites. It has been, in fact, an important application of the aerial survey method, and it resulted in a considerable saving of time.

MR. SIDNEY SMITH, Assistant Keeper in the Department of Egyptian and Assyrian Antiquities at the British Museum, has been appointed Keeper of the Department in succession to Dr. H. R. Hall, who died on Oct. 13 last.

WE much regret to record the following deaths: Mr. A. B. Basset, F.R.S., a vice-president in 1892–94 of the London Mathematical Society, on Dec. 5, aged seventy-six years; Sir Otto Beit, Bart., K.C.M.G., F.R.S., well known for his generous benefactions for medical and other scientific research, on Dec. 7, aged sixty-five years; and Sir Francis Ogilvie, C.B., formerly Director of the Science Museum, South Kensington, on Dec. 14, aged seventy-two years.

THE Christmas Lectures at the Royal Institution will be delivered this year in the reconstructed lecture theatre of the Institution by Prof. A. M. Tyndall, H. O. Wills professor of physics in the University of Bristol, on the electric spark. The first lecture will be given on Dec. 30, at three o'clock, on "Some Properties of Electrified Bodies". The remaining five lectures will deal with the spark as a

current of electricity, air as a conductor, and the mechanism and properties of sparks and arcs.

As already announced, the twenty-first Annual Exhibition of the Physical and Optical Societies is to be held on Jan. 6-8 at the Imperial College of Science, Imperial Institute Road, South Kensington; it will be open in the afternoon from 3 P.M. to 6 P.M., and in the evening from 7 P.M. to 10 P.M. To mark the coming-of-age of the Exhibition, it will be opened formally by Sir Arthur Eddington, on Jan. 6 at 2.30 P.M. Two discourses, with experiments, will be given at 8 P.M. on Jan. 7 and 8: Mr. E. Lancaster-Jones, "Searching for Minerals with Scientific Instruments", and Sir Gilbert Walker, "Physics of Sport". Members of learned societies can obtain tickets of admission from their secretaries; others may obtain tickets on application to the Secretary, the Physical and Optical Societies, 1 Lowther Gardens, Exhibition Road, London, S. W.7. No tickets are required for Jan. 8.

DR. T. A. STEPHENSON, senior lecturer in the Department of Zoology at University College, London, has been appointed professor of zoology in the University of Cape Town in succession to Prof. L. T. Hogben. Prof. Stephenson received his education in zoology and allied subjects at the University College of Wales, Aberystwyth, where he was afterwards demonstrator in zoology for about three years. His earlier research work was on the morphology and ecology of the sea anemones, and more recently he has studied the ecology of corals and coral-reefs; in 1923 he made an investigation of the Guernsey *Haliotis* fishery. In 1928–29 he was in charge of the shore-work of the Great Barrier Reef Expedition. Prof. Stephenson is the author of various publications dealing, among other subjects, with the Actiniaria of the world and British orchids, but his principal item is Vol. 1 of a monograph on the British sea anemones, which is one of the Ray Society publications.

THE annual meeting of the American Association for the Advancement of Science will be held at Cleveland on Dec. 29–Jan. 3. This will be the fourth occasion on which the Association has met at Cleveland. The address of the retiring president, Dr. Robert A. Millikan, director of the Norman Bridge Laboratory of Physics and chairman of the executive council of the California Institute of Technology, will be delivered on Dec. 29. Dr. Edwin B. Wilson, professor of vital statistics in the School of Public Health, Harvard University, will deliver the Gibbs lecture (under the auspices of the Association and the American Mathematical Society) on the afternoon of Dec. 30; and Dr. C. E. K. Mees, of the Eastman Kodak Company, will give the Sigma Xi lecture on the same evening. General lectures have been arranged for every afternoon and evening of the meeting, and a science exhibition will also be open. It is also announced in *Science* that the first of the new series of summer meetings of the American Association for the Advancement of Science will be held at Pasadena, California, on June 16-20, 1931, at the California Institute of Technology, the Huntington Library and Art Gallery, and the Mount Wilson Observatory.

ON Nov. 10, the University of Colorado celebrated the twenty-fifth anniversary of the theory of relativity; it was on Sept. 26, 1905, that Einstein's first paper on relativity, entitled "Zur Elektrodynamik Bewegter Körper", appeared in the *Annalen der Physik*. A banquet was given in the Memorial Union Building, after which addresses were given by various members of the faculty. Dean O. C. Lester, of the Graduate School, spoke on "The Changed Outlook on Physical Theories"; Dr. V. P. Lubovich, assistant professor of physics, spoke on "Does the Inertia of a Body depend upon its Energy Content?"; Dr. Walter B. Veazie, of the Department of Philosophy, discussed "Relativity and Philosophy"; and Dr. Frank E. E. Germann, professor of chemistry, spoke on "Chemistry and Relativity". A painting of Dr. Einstein by Miss Virginia True, of the Art Department, was also unveiled.

THE Augustus and Alice Waller Memorial Research Fund is held in trust by the Council of the London (R.F.H.) School of Medicine for Women, but is not restricted to members of that institution. A permanent income of about £100 a year is provided for the primary purpose of making grants, usually of small sums, for the purchase of research apparatus. Twenty-nine grants representing a total sum of £540 have been made, varying in amount from £3 to £48, the average grant being £18. The grants have been given for research work in physiology, physics, chemistry, anatomy, pharmacology, and pathology. It is felt that the Fund is fulfilling its purpose as a memorial to Dr. and Mrs. Waller, who themselves devoted their lives to research. The sum of £105, with accrued interest, subscribed for a memorial at St. Mary's Hospital, will be used to help equip one of the physiological laboratories in the new school to be known as the "Waller Memorial Laboratory". It is expected that the laboratories will be completed in about eighteen months' time.

THE report of the Irish Radium Committee for 1929 has been published by the Royal Dublin Society (*Sci. Proc. Roy. Dub. Soc.*, vol. 19, [separate issue] No. 42). The large quantity of 14,730 millicuries of radon was issued during the year. Reports from several surgeons are included, and some surprisingly good results are recorded in some cases of cancer of the breast, lip, and skin, and in one of pelvic sarcoma, though it has to be admitted that there are numerous failures. In some of the latter, nevertheless, the patient's condition for the time being is often much benefited.

THE first number of a new periodical, *Bulletin Météorologique de l'Observatoire Météorologique de Beograd*, dated 1928, has recently been received. Its contents, however, consist of the daily observations of the various meteorological elements at 3 hours on each day at numerous stations in Serbia during the half year July–December 1905. The *Bulletin* is a sequel to two former publications, one—the monthly bulletin

of the Belgrade Observatory which was published for the period 1902–June 1905, and the other a separate publication giving data from 1904–June 1905. The Observatory archives contain data, for the most part not reduced, for the whole period 1888–1914. It is hoped to publish these and later data in further issues of the *Bulletin*, so that in twelve to fourteen years the whole material will be made available. Meteorologists in other countries will join in wishing that this modest hope may be fulfilled.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant master for mathematics and physics in the Smith Junior Nautical School, Cardiff—The Director of Education, City Hall, Cardiff (Dec. 27). An assistant science teacher at the Central Municipal Technical School, Liverpool—The Director of Education, 14 St. Thomas Street, Liverpool (Dec. 31). A male assistant under the Department of Scientific and Industrial Research for work in connexion with research on fruit—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W.1 (Dec. 31). A professor of pathology in the University of Glasgow—The Secretary, The University Court, University, Glasgow, W.2 (Jan. 7). A graduate woman teacher for arithmetic and geometry at the Bloomsbury Trade School, Queen Square, W.C.1—The Education Officer (T.1), County Hall, S.E.1 (Jan. 9). A research assistant in plant breeding at University College, Dublin—The Secretary, University College, Dublin (Jan. 15). A mechanic and laboratory assistant in the physics laboratory and workshop of the University of Cape Town—The Registrar, The University of Cape Town, P.O. Box 594, Cape Town, South Africa (Jan. 20). A professor in mathematics in the University of Dacca, East Bengal—The Registrar, University of Dacca, East Bengal, India (Feb. 7). A professor of economics and political science at the University College of Wales, Aberystwyth—The Financial Secretary, University College of Wales, Aberystwyth (Feb. 14). A principal of the Dundee School of Economics and Commerce—The Town Clerk, Dundee.

Our Astronomical Column.

A Solar Eruption on Nov. 25.—At the meeting of the Royal Astronomical Society on Dec. 12, observations were described of a solar eruption that was seen near the centre of the sun's disc on Nov. 25 with the spectrohelioscope at Greenwich. Eruptive prominences possessing velocities of 100 km./sec. or greater have been often observed in hydrogen light at the sun's limbs with the spectroscope by recording their linear displacements with time. Similarly they are recorded in spectroheliograms in hydrogen or calcium light. The spectrohelioscope in addition enables the observer to follow the changes of the prominences as they are carried by the sun's rotation across the disc as absorption markings. A simple device for progressively changing the wave-length of the light entering the eye enables the observer to locate and measure the line of sight component of the radial velocity outwards or inwards from the sun with which the absorption marking may be moving.

The phenomena observed on Nov. 25 evidently represented the end-on view of an eruptive prominence blown out of the sun's chromosphere with a maximum observed velocity of 450 km./sec. Forty-five minutes before the eruption, an apparently stable dark marking was visible; at $10^h\ 34^m$ G.M.T. the velocity rose within a few minutes from 40 km./sec. to about 400 km./sec. At 11^h cloud stopped the observations, but the eruption was then declining, and part of the gaseous structure was descending at about 100 km./sec. Contemporary with the appearance of those rapidly moving masses of hydrogen gas, brilliant patches of hydrogen with little or no radial velocity made their appearance. It may be added that the phenomena described could have been photographed with a spectroheliograph had the second or selecting slit been set at appropriate distances from the $H\alpha$, or H or K lines of the solar spectrum so as to allow for the Doppler displacements equivalent to the velocities observed.

Autumn Fireballs.—Mr. W. F. Denning, 44 Egerton Road, Bristol, writes as follows: "Several large fireballs or meteors have been observed during the last two months, and further observations of the following would be welcomed:

Oct. 24, 8.24: Brilliant meteor, fell perpendicularly down in southern sky, seen at Bristol.

Nov. 16, 9.46 P.M.: Estimated four times as bright as Jupiter; path, 165° + 55° to 135° + 35°; duration 5 sec.; seen from Nuneaton, Warwick.

Nov. 16, 2.30 A.M.: Splendid meteor, gave a brilliant flash and left a fiery streak for several minutes; appeared in the eastern sky and moved from north to east; fell at angle of 45°; Campbeltown, Scotland.

Oct. 30, 10.5 P.M.: A fireball passed along parallel to the horizon eastwards; altitude low, first seen when slightly east of the moon and endured 8 to 10 seconds; disappeared in the south-south-east; observed by several people from Edinburgh and described in the *Scotsman*.

Nov. 27, 11.6 P.M.: Reported by observers in Cornwall and Devonshire; it lit up the whole countryside. As seen at Lostwithiel, it moved from north-west to south-east and ended near Orion; as viewed from St. Agnes, it shot almost perpendicularly down the southern sky and traversed the region of Perseus or border of Aries and Taurus and vanished near Orion."

Stellar Absorption Band near λ4200.—Recent work by Dr. A. V. Douglas, described in the *Monthly Notices* of the Royal Astronomical Society for October 1930, throws some light on the discussion concerning the origin of this band. Previous work by Elvey and Zug showed that in the case of the Yerkes spectrograms its presence in stellar spectra could be accounted for by absorption in the optical system. Shapley, also, has withdrawn his earlier identification of cyanogen as the origin in early type stars. Miss Douglas, by means of experiments similar to Elvey's, has been unable to trace any selective absorption in the optical train of the Ottawa 15-inch refractor; whereas, in the case of three cepheid variables examined by her, the absorption band is not only strong but also exhibits periodic variations in intensity in phase with similar variations of enhanced lines. The stellar origin (most probably cyanogen) is thus strongly supported. No mention is made of early type spectra, and the origin in such cases is still not definitely settled.

Research Items.

Megalithic Structures in Ceylon.—In the course of his archæological summary in the *Ceylon Journal of Science*, vol. 2, pt. 1, Mr. A. M. Hocart reports the existence of a dolmen at Padiyagampola, near Rambukkana, the only one of its class that has so far been discovered in Ceylon. It was brought to the notice of the Archæological Department by Mr. F. Lewis, of Kandy, and is situated on the foothills of the central mountain range of the island. It is constructed of three upright slabs with a covering stone placed horizontally on them. The two long upright slabs measure roughly 12 ft. by 5½ ft. each; the upright stone at the north end measures 3¼ ft. by 5½ ft. The covering stone, irregular in shape and measuring 17 ft. by 15 ft., is in a somewhat 'slanting' position and has cracked. The thickness of the slabs is about 15 inches. The room measures internally 11 ft. by 6½ ft., and the height from the present ground level to the covering stone is 6 ft. The southern side is open and there is a passage on the north side also. The stones bear no marks of chiselling, except on the western side, but this is probably not an original feature. Trilithons still survive in Ceylon, where they are called *gonatu*. A Sinhalese statement says that "when pregnant women die, they are reborn as *bodiri* birds. *Gonatu* are made to liberate them from this. Wayfarers place on top the loads that they carry either on their heads or shoulders, and sit by and rest. By that grace the women who are born as *bodiri* birds are liberated from that, and are born in a better world." It is interesting to compare with this the fact that the great trilithon of Tongatabu is known in Tongan as the "Burden of Maui".

Pueblo Ruins in Colorado.—The excavation in 1928 of early Pueblo ruins belonging to the period known as Pueblo I, in the Piedra River district of southwestern Colorado, is described by Mr. Frank H. H. Roberts, jun., in *Bull.* 96 of the Bureau of American Ethnology. The Piedra River is one of two cultural sub-centres in the San Juan Basin—one of the more important minor districts of Pueblo culture—the other being Aztec. The latter, however, towards its final period came under the domination of the Mesa Verde peoples. The Piedra River district was virtually unknown to archæologists before 1921. Early excavations up to 1923 and surveys in later years did little more than show the great importance of the district as an archæological site. Ruins and sites extend along both banks of the river for a distance of more than 15 miles. Three types of houses were found, but while the first is thought to show a late Basket-Maker influence, the two later illustrate definite pueblo forms of the early period. The outstanding constructional development of the period was that of the rectangular, perpendicular-walled building which made possible the joining of single-roomed houses into a communal dwelling of many contiguous rooms, one of the typical features of the true pueblo complex. Ruins of only two of the ceremonial kivas were uncovered—an unusually small number of specialised ceremonial rooms for so large a number of house-group units. This is taken to suggest that this feature of pueblo culture was still in a developmental stage. The pottery also shows that that industry was in a transition stage. Among the most significant new features are the banding on the necks of the vessels, the shift from banded to coil ware, the use of a slip, and the elaboration of painted decoration. Bone and stone implements were not abundant, and consist of a few general forms. Burials were in the contracted position and accompanied by mortuary offerings of pottery.

Insect Control by Aeroplane.—*Circular* 123 (issued August 1930) of the United States Department of Agriculture describes the relative values of dusting the blueberry crop, when infested by larvæ of the fly *Rhagoletis pomonella*, by aeroplane and by ground machines. The authors, Messrs. F. H. Lathrop and C. B. Nickels, state that trials carried out in the State of Maine indicate that calcium arsenate is effective as a dust in controlling this insect. Under favourable conditions, when this material is discharged from an aeroplane flying at a height of about 25 feet, at a speed of 60 miles per hour, the results are as effective as when it is delivered on the crop by ground machines. In the case of this particular insect pest, however, the balance was rather in favour of the latter method. The general topography and the usual atmospheric conditions were against the use of the aeroplane. Heavy fogs during early morning, at the time when the aeroplane could be most favourably used, reduced the length of period available, and it was doubtful whether enhanced speed compensated for the shortness of the time when the aeroplane could be employed.

Parasites of the Pine-shoot Moth.—In the *Bulletin of Entomological Research*, vol. 21, October 1930, pp. 387-412, Dr. W. H. Thorpe describes the results of a preliminary study of the parasites of the pine-shoot moth (*Rhyacionia buoliana*). The investigation was undertaken at the request of the Dominion Entomologist of Canada, where the experiment of attempting to control that insect by biological methods is being undertaken. Although the moth is by no means kept under complete control by parasites in Europe, it was considered possible that the introduction of certain of the more important of these enemies, free from their natural hyperparasites, might result in checking the spread of that pest in Canada. The investigations were carried out at the Farnham House Laboratory of the Imperial Institute of Entomology on material obtained from Norfolk, Suffolk, and the New Forest. It appears that twenty-eight species of primary and secondary parasites affect the insect in question, of which the dominant or 'key' forms appear to be the Braconid *Orgilus obscurator* and the two Ophionines, *Cremastus interruptor* and *Omorgus mutabilis*. Consignments of these species have been transmitted to Canada, where the first two mentioned have become established and have been able to pass the severe winter successfully. A brief account is given of the salient features in the biology of each species, and the chief diagnostic characters of the adults are described, along with those of the mature larvæ. The practical outcome of the experiment will be watched with interest, but some years must elapse before any definite results are forthcoming.

Trematodes of the Dry Tortugas.—Mr. O. R. McCoy has continued his investigations into the life-histories of marine trematodes (Year Book No. 28, Carnegie Institution of Washington, p. 290). Special attention was given to the behaviour of certain cercariæ and some interesting experiments were carried out. Three new monostome cercariæ with large, more or less highly pigmented tails and pigmented eye-spots, all infesting the gastropod *Cerithium litteratum*, were studied. The full-grown active larvæ of each species are strongly photo-positive, and in one species the cercariæ aggregated in masses, the individuals of which moved together as a unit. The posterior half of the tail tapers suddenly to form a sticky ribbon and the tails become tangled together, the head ends of the animals projecting outwards. It is suggested that

such aggregations occur naturally in the branchial chamber of the mollusk. On p. 295, Mr. H. M. Miller and Mr. O. R. McCoy describe their experiments on the behaviour of *Cercaria floridensis* in relation to its intermediate hosts. This larva is also photo-positive, and swims towards the light if any shadow fall upon it, the habit apparently influencing considerably any experiments. Several species of small fishes known as 'grunts' (*Hoemulon* spp.) were successfully infected, the trematodes encysting under the scales and in the fins.

Paryphantidae of New Zealand.—The larger New Zealand land snails belonging to the genera *Paryphanta*, *Wainuia* (n. gen.), and *Rhytida* have now been recorded and described in full detail by A. W. B. Powell (*Rec. Auckland Inst. and Mus.*, vol. 1). How the distribution of the species is governed by present physical features and what their hypothetical ancestry and development may have been are also discussed. *Rhytida* and its close allies have a far wider range than *Paryphanta* and consequently a probably greater antiquity and more ancient dispersal. *Paryphanta* doubtless originated from *Rhytida*-like stock within the New Zealand faunal area and achieved its greatest distribution during the great land extensions of the Lower Cretaceous, reaching Tasmania and Victoria, Australia. The single new species described, *Paryphanta superba*, is the largest of the genus and indeed of the group under discussion; so, that it has hitherto escaped discovery is somewhat remarkable.

The Crab Genus *Actæa*. Mr. Lee Boone makes some interesting remarks on these crabs, belonging to the Pilumnidæ, in a paper entitled "Notes on the West Indian Crabs of the Genus Actæa" (*Bulletin of the American Museum of Natural History*, vol. 61, Pt. 3: 1930). He believes that *Actæa bifrons* Rathbun is merely the young of *Actæa setigera*, but Miss Rathbun, in her recent work on "The Cancroid Crabs of America", amongst the material examined records an ovigerous female of *A. bifrons*, this seems somewhat doubtful. The species of *Actæa* are all very hairy and live in cavities of corals and sponges. Always sluggish in their movements, they are easily overlooked. For the first time, detailed colour notes are given of a specimen of *Actæa acantha* and of the West Indian representative of *A. rufopunctata nodosa*.

Respiratory Products and Plant Regeneration.—K. Kakesita in the *Japanese Journal of Botany*, vol. 5, No. 2, 1930, advances the view that the regenerative activity of the leaf of *Bryophyllum calycinum* may be stimulated by the accumulation of the products of intramolecular respiration within the leaf tissues. This view is suggested as the result of experiments, in which the leaf, still attached to the plant, was caused to produce buds and roots by placing the whole plant in a warm bath, or in an atmosphere of hydrogen. Injection of substances regarded as likely products of such intramolecular respiration, especially ethyl alcohol, is also said to have produced regenerative activities. Evidence is supplied that acetaldehyde and alcohol accumulate in the plant as the result of the warm bath treatment or as the result of surrounding the plant with hydrogen. More acetaldehyde and alcohol were also found in isolated than in attached leaves, so it is suggested that regeneration, as the result of isolation, is also the result of intramolecular respiration in the leaf tissues.

Root Stock Influence.—In the case of British fruit trees, every orchard is filled with worked trees, in which a desirable scion is grafted upon a root system, derived either from another seedling or a vegetatively propagated 'clone' which roots relatively readily. Of recent years the East Malling Experiment Station has emphasised the possibility that propagating a scion 'clone' upon a suitable root stock 'clone' might go far to standardise growth and yields in orchard practice. An examination of stock scion relationships, therefore, by the Director of the East Malling Experiment Station, Mr. R. G. Hatton, in the Masters Memorial Lectures, published in the *Journal* of the Royal Horticultural Society for September, may be expected to summarise the results of experimental work in this interesting field, and the reader will not be disappointed. Some American workers are more inclined to stress the influence of the common scion in impressing uniformity upon the variable seedling material used as source of roots in American practice, and Mr. Hatton points out that this may be the result of the different method of working in the two countries. Much American material is 'bench-grafted' upon root pieces, whilst English unions are made by budding or grafting upon the stem of the stock above ground-level. Mr. Hatton supplies evidence of root stock influence upon scion yield, vigour, and habit of growth under the English method of working. He also examines the possibility that this influence may be in part due to the stem piece of the stock left above its root system, and finds some evidence, in double worked trees, that the intermediate piece of stem may influence the character of the scion above. This argument, if capable of extension, would seem likely to give away the case. If, as is argued, five or six feet of the stem of a vegetatively propagated intermediate can largely produce uniformity, even when the intermediate is worked on seedling stocks, then the conclusion would seem to be that the same uniformity might be expected if the stem piece belonged to the scion. A very useful bibliography is appended.

Bathymetry of the Oceans.—In the *Hydrographic Review* for November, Lieut.-Com. H. Beneker has a paper on the bathymetry of the oceans, in which he discusses the material available for detailed charts. The most valuable part of the paper, however, lies in the appendices. The first of these is a chronological list of the important vessels from 1800 onwards which have contributed to deep-sea knowledge. The dates of foundation of various oceanographic and other institutes are also noted. Following this list is a catalogue of ocean deeps as known up to the present. These are listed under oceans, with the latitude and longitude of the greatest depth. Each is given the generally accepted name. There is also a list of important shoals of all oceans unconnected with continental land masses or islands. These lists are not complete in all details but are published in the hope that any inaccuracies or omissions will be noted and a communication sent to the International Hydrographic Bureau at Monaco.

Earthquakes at Ito (Japan).—The remarkable series of slight earthquakes, 3684 in number from Feb. 13 to April 11, at Ito, on the west coast of Sagami Bay, are described in a previous note (NATURE, Aug. 30, p. 326). While the earthquakes were occurring almost incessantly, a new series of precise levellings was carried across the district. Comparing the measurements with those made in 1924, it appears that, close to Ito, a tract of coast 12 miles long has risen, by so much as 3 ft. 2 in. at a point two miles south of Ito, while at either end of the tract there has been a slight subsidence, of 4 in. to the north and 10 in. to the south (*Earthq. Res. Inst. Bull.*, vol. 8, pp. 375-376; 1930).

Non-metallic Ore Deposits of Russia.—An important work on this subject has been published—under the editorship of I. I. Ginsburg, S. V. Konstantinoff, I. D. Kourbatoff, V. A. Unkovsky, A. E. Fersmann, and D. I. Shcherbakoff—by the Academy of Science of U.S.S.R. (Leningrad, 1926–29: 4 volumes, in Russian). Altogether there are seventy-five original articles, each dealing with compounds of an element or a group of elements, written by a specialist in a given subject. Each article contains the following features: a general description of the mineral and the ore, together with its chemical and physical properties, occurrence in U.S.S.R. and elsewhere, mining and working of the material, technical applications, world markets and prices, and also a special part devoted to a detailed description of Russian occurrences. A comprehensive list of the literature, both Russian and foreign, is included with each article. Indexes and table of contents are included in every volume. This important publication can be recommended as an authoritative source of information to all interested in Russian mineral wealth and industry.

The Michelson-Morley Experiment.—A repetition of the experiment of Michelson and Morley on ether-drift has been carried out by G. Joos at Jena, and is described in a recent paper (p. 385) in the current volume of the *Annalen der Physik*. Several novel features have been introduced in the mechanical and optical arrangements. The frame for the support of the mirrors was built of quartz slabs (made by Schott), the light path being 21 metres. Transmission of vibrations was avoided, not, as has often been done previously, by floating in mercury, but by hanging the interferometer on a great number of springs, oscillations of the suspended system being damped by hairs. The fringes were recorded by photography and measured up in a microphotometer, the final result being that any effect due to an ether-wind was less than 1/1000 of a fringe, or that the ether-wind is less than 1·5 kilometre per second.

Measuring an A.C. Voltage by balancing against a D.C. Voltage.—In the *Journal of Scientific Instruments* for December, S. Whitehead and D. Barham give an account of very interesting experiments showing how an a.c. voltage may be measured by means of a quadrant electrometer and a d.c. potentiometer. The method used is a null method and was originally described by J. Swinburne many years ago. Theory shows that the result found is independent of frequency and wave form. The experiments show that this is true at ordinary frequencies, the maximum inaccuracy being of the order of 1 in 5000. The authors point out minor defects of the method, mainly due to the contact difference of potential and the time taken for the preliminary adjustment. The range of the voltage that can be measured is also limited. Probably, however, if the electrometer were specially designed, these disadvantages could be got rid of, and the sensitivity of the instrument greatly increased.

Lightning.—The lecture which Dr. G. C. Simpson gave to the Junior Scientific Club of Oxford University on "Thunder and Lightning" (Oxford: Vincent Printing Works) is a very helpful contribution to our knowledge of a phenomenon which has been closely studied from the earliest ages. Naturally, there have been a very large number of theories advanced to explain the effects produced, but only two, namely, Wilson's, based on electrical induction, and Simpson's, based on the breaking up of raindrops, are mentioned. When the electric stress breaks down the air at any point, the rent made is at first very local; but once made, it rapidly extends in the form of a narrow channel. The most important characteristic of the rent is that it can only extend in the direction away from the seat of the positive electricity. As the channel extends, it tends to branch, and each branch becomes a new rent. Thus when we see a lightning discharge, we can tell from the branching which way it has extended and where the positive electricity is situated. The rate at which the lightning channel grows is usually very great. Laboratory experiments seem to indicate that it could be as fast as a tenth of the velocity of light. On the other hand, we know that in certain circumstances the channel can grow relatively slowly. The light associated with a lightning flash is due to the recombination of electrons and ions within the ionised channel. The first discharge which opens the channel leaves the air within it very highly ionised and an electrical current can pass along it. Hence it remains ionised for an appreciable time after the visible discharge has ceased. Dr. Simpson showed very interesting photographs of various abnormal types of lightning-flash. He also described two recent occurrences of ball lightning which illustrate its chief features. He confesses, however, that he does not yet see even the beginning of an explanation of it.

Condensation of Electrons on Metals.—The amount of heat liberated when an electron of zero kinetic energy is absorbed by a metal from the gas phase, a quantity of importance in connexion with the theory of electric discharges through gases, was determined several years ago by Prof. K. T. Compton and C. C. van Voorhis from an ingenious combination of microcalorimetry with Langmuir's method for using exploring electrodes. More complete results from similar measurements, which are given in the first November number of the *Physical Review*, now establish definitely that the ionised gas from which the electrons are drawn has a specific effect on the properties of the metal surface. For platinum, for example, the heat of condensation of an electron is equivalent to 5·21 volts in the presence of nitrogen and to 4·39 volts in the presence of helium, and, moreover, contact potential differences between the exploring electrode and another of presumably constant properties change in general with time after the exploring electrode has been cleaned electrically *in situ*. It is suggested that the effect of at least the inert gases is due to their positive ions; these possess the same number of electrons as halogens, and might thus be expected to be chemically active. The permanence of any compounds formed on the metal surface is nevertheless small, since in the discharges studied it would only be necessary for each incoming positive ion to remain on the surface for one-thousandth of a second to keep ten per cent of its surface covered. This research provides a good illustration of the accuracy which can now be attained in problems connected with the electric discharge in gases, the error in the heats of condensation being believed to be well within one per cent.

Nickel as a Hydrogenation Catalyst.—Although a very large amount of work has been done on the use of nickel as a catalyst for the hydrogenation of organic compounds, systematic investigations begun by Adkins and Cramer, the first instalment of which appears in the November number of the *Journal of the American Chemical Society*, will provide much more detailed and useful information in many cases than is now available. The paper describes in a tabular form the results of experiments made with forty-five organic compounds with which satisfactory reductions were obtained. The apparatus permits of the study of the selective reduction of one of two reducible substances through the control of the temperature or time interval of reduction.

Transport of Nitrogen in the Plant.

THE general question of translocation in plants demands attention, not only because of its ractical importance in horticulture, but perhaps ven more so because of its intensely controversial ature. Recent work on the translocation of carbohydrates in the cotton plant, by T. G. Mason and . J. Maskell, has already been reviewed in NATURE 123, pp. 133-135; 1929). Maskell and Mason have xtended their work to the translocation of nitrogen. 'his work, which appears as *Memoir* 2, Series B (1930), rom the Cotton Research Station, Trinidad, is as aluable a contribution to the literature of nitrogen netabolism as to that of translocation.

The experimental technique is very similar to that dopted in the work on carbohydrates; indeed, in nany cases, the nitrogen analyses were made on amples which had already yielded some of the data n the earlier papers. As before, the procedure nvolves various ingenious combinations of ringing, artial ringing, defoliation, etc., and a rather extensive tatistical analysis of analytical data obtained for the arious nitrogenous fractions. It is interesting to eflect that Malpighi ringed stems in the late seventeenth century, and at least so early as 1731 such practices as ringing, partial ringing, defoliation, etc., vere the staple procedures in the attempt to elucidate he "circulation or non-circulation of the sap". Stephen Hales in his "Vegetable Staticks" describes xperiments in which the experimental detail seems tartlingly modern. However, in his preface he found t necessary to enlighten at length those of his readers "who complain that they do not understand the ignification of those short signs or characters (; · ; ·; =) which are here made use of in many of he calculations, and which are usual in Algebra". Whilst two hundred years cannot be said to have produced very outstanding modifications in experimental technique, beyond the adoption of modern nalytical methods instead of fragmentary observations n growth, leaf fall, colour, etc., one can see a vast hange in the method of interpreting results. Maskell nd Mason make very full use of statistical methods, nd apparently place a greater confidence in their eaders' mathematical comprehension.

Part I of the paper now before us, containing observations on the downward movement of nitrogen n the stem, consists of experiments designed to test he idea that the leaf is the principal seat of protein synthesis, and its greater claim than other organs for norganic nitrogen rests on its 'transpiration pull'. Chibnall's contention that there are diurnal changes in nitrogen (total) content of the leaf is confirmed by Maskell and Mason for the cotton plant. They find the nitrogen content higher by day than by night. Though evidence for similar changes in the bark is not so conclusive, the tentative suggestion is made that the leaf changes lead to similar concentration changes in the bark which lag somewhat behind those of the leaf. The effects of ringing on nitrogen movements are interesting relative to Curtis's suggestion that nitrogen (organic and inorganic) moves not in the xylem but in the phloem. Maskell and Mason complete their experiment 24 hours after ringing. They find that the nitrogen content of the leaf samples (3 leaves from near the apex of each of 10 plants) from ringed and normal unringed groups show normal diurnal changes and are practically identical. It is concluded that ringing has not interrupted nitrate movement, which is therefore in the wood.

This view, however, assumes that a redistribution of nitrogen between the leaves above the ring may be neglected. It is worthy of note that the sampled region is that most vigorously growing, and the possibility remains that it has drawn nitrogen, via the bark, from the lower leaves above the ring. This would be more possible in a short time experiment like the one described. Sampling of the entire leaf and stem above the ring clearly offers (in the cotton plant) considerable mechanical difficulties. The wood and bark of the ringed plants above the ring (seven inches sampled) show a significant increase in total nitrogen content, and similar samples below show a decrease. This is in harmony with the view that ringing prevents downward movement in the stem, though not that from leaf to bark. It does not necessarily indicate that there has been an upward movement of inorganic nitrogen in the wood past the ring. Curtis previously claimed (*Amer. Jour. Bot.*, 1923) that leaves of ringed twigs of lilac, privet, etc., increased in nitrogen content much less than corresponding ones of unringed plants. Maskell and Mason reinterpret one of Curtis's experiments to support the view that leaves above a ring import nitrate via the wood and export organic nitrogen via the bark. However, in the absence of data that an actual increase of total nitrogen had occurred above the ring, such an interpretation is inconclusive. Since it is known that transfer of nitrogen from one lateral branch to another does not readily take place (Auchter Agric. Expt. Stat., Univ. of Maryland, *Bull.* 257, 1923), it is improbable that the twigs in question imported organic nitrogen from the rest of the plant.

The possibility remains, therefore, that the nitrogen entering the defoliated region of stem above a ring came from the young, active leaves above it (4 pairs), whilst that entering a similar region below a ring came only from the basal leaves on that same twig (probably not more than 4 or 5 pairs), which were older, less active in protein synthesis (August), and in competition with younger leaves on other shoots for the nitrate application to the soil. Hence the seeming inconsistency referred to by Maskell and Mason, that four pairs of leaves above a ring supply to a defoliated region of stem 70 per cent as much nitrogen as the rest of the plant to a similar region below a ring, may be more apparent than real. In view of their repetition of the criticism that Curtis's results were due to transpiration effects caused by blocking of the xylem, one is reminded of the claim (*Ann. Bot.*, 1925) that complete cutting of the xylem, leaving the phloem intact, has a smaller effect on upward translocation than the reverse procedure. In another connexion Mason and Maskell have suggested, whilst admitting the significance of some of these results, the contradictory view that the superiority of the cut xylem group may be due to a few xylem elements regenerated in six days on the inner bark, whilst the inferiority of the cut phloem group may be due to plugging of the xylem. Surely if a few regenerated xylem elements are adequate, the xylem of the cut phloem group would have to be plugged to an inconceivable degree.

All this indicates the difficulty of interpreting the apparently simple ringing experiments. Many will regard the upward path of inorganic nutrients as still open to question. If Maskell and Mason are right in their contention that inorganic nitrogen moves with the transpiration stream, one is left with the curious situation that one simple solute (cane sugar) moves upward and downward in the phloem and another (inorganic nitrate) moves apparently with the water. Experiments on downward movement of nitrogen in the bark with a restricted channel of transport show that the rate per unit area increases as the available

area decreases. As suggested in the case of sugars, this is suggestive of a movement analogous to diffusion.

Part 2 of Messrs. Maskell and Mason's paper consists of observations on concentration gradients in relation to nitrogen movement. The previous work on sugar movement in the bark by the same authors showed that it was always from a region of high to one of low concentration. No such relation could be found for downward movement of nitrogen in the bark, which proceeds against a well-defined negative gradient of total and crystalloid nitrogen. All attempts to distinguish between mobile and storage forms by fractionation of the total nitrogen fail to reveal a well-defined positive gradient of any nitrogen fraction in the direction of movement, unless this be the rather elusive residual or unfractionated nitrogen. Subdivision of the bark into inner and outer zones disproved the possibility that positive and negative gradients in the different regions mask each other.

Part 3 of the paper under notice consists of an attack on the problem of movement in relation to concentration gradients by determining the change in existing nitrogen gradients caused by stoppage and reversal of nitrogen movement. The desired conditions were obtained by suitable combinations of ringing and defoliation. Unlike the situation in the case of the sugars, zero nitrogen movement is associated not with zero gradient but with a well-defined negative gradient of protein and crystalloid nitrogen. When downward movement of nitrogen is still proceeding, the negative gradient of total and crystalloid nitrogen is smaller than when movement has ceased: that is, the change from zero movement to downward movement is associated with the production of a positive gradient superimposed upon the existing negative gradient. This superimposed gradient is termed the dynamic gradient. An algebraical method of estimating the dynamic gradient, assuming a relatively constant storage gradient, is described. It is estimated that the degree of acceleration over diffusion previously found for sugars would suffice to account for the actual nitrogen movement with the observed concentration gradients (dynamic) of total nitrogen, protein nitrogen, and amino acid nitrogen. The localisation of the dynamic gradient largely in the inner bark suggests its association with the sieve tubes. It appears that the accelerating mechanism presumably associated with the sieve tubes acts impartially on sugar and nitrogen compounds.

F. C. S.

Influence of Steam on the Combustion of Carbonic Oxide.

PROF. W. A. BONE, who delivered the third Liversidge Lecture before the Chemical Society on Dec. 11, chose for his subject "Fifty Years' Experimental Research upon the Influence of Steam on the Combustion of Carbonic Oxide (1880–1930)". Commencing with the late Prof. H. B. Dixon's abandonment of classics for science in 1876, Prof. Bone referred to his repetition of Bunsen's work and his observation (communicated to the British Association at Swansea in 1880) that a mixture of carbon monoxide and oxygen, if dried at the ordinary pressure over phosphorus pentoxide, becomes non-explosive when sparked in the usual way. Examination of the effect of various third substances led him to adopt the view that the action of moisture is chemical and due to the hydrogen contained in it, the pure, dry reactants being mutually inert. Moreover, the speed of flame propagation had a minimum value in the dried mixture and a maximum value in the presence of nearly 6 per cent of moisture.

The investigation was extended in 1884 by Prof. H. B. Baker, who showed that, in dry oxygen, carbon burns essentially to carbon monoxide. Prof. Bone explained the precautions necessary in such experiments, and mentioned Morley's work in 1887 and 1904; long contact of a gas with phosphorus pentoxide is unnecessary, but there is considerable difficulty in drying the surface of the containing vessel. Continuing, he referred to Traube's observations (1885) that the flame of dry carbon monoxide is extinguished by plunging it into dry air, and that when the carbon monoxide flame is directed on to ice, hydrogen peroxide may be detected; hence the scheme

$$CO + O.O + OH_2 = CO_2 + H_2O_2$$

was proposed. Mendeléeff, however, preferred the series:

$$CO + H_2O \qquad\qquad H_2O_2;$$
$$H_2O_2 + CO = CO_2 + H_2O;$$

and Prof. H. E. Armstrong regarded the case as one of 'reversed electrolysis'. Lothar Meyer in 1886 showed that dry, 'non-explosive' carbon monoxide and oxygen could be caused to combine non-explosively by means of a powerful discharge, indicating that direct oxidation requires a higher temperature than indirect. Beketoff postulated the necessity for the presence of oxygen atoms, which were provided by steam more readily than by oxygen molecules themselves.

Dixon's experiments in 1886 showed that in the combustion of dry cyanogen with excess of oxygen, carbon dioxide is always formed to completion, the monoxide being produced intermediately. Smithells and Dent, using the flame separator, found that the outer cone of the dry cyanogen flame will burn in air dried by sulphuric acid only if the cones are not widely separated, showing that the length of life of the carbon monoxide is a determining factor. It was confirmed in 1896 by Dixon, Strange, and Graham that the carbon monoxide, freshly formed in a dry cyanogen explosion, will combine directly with excess of oxygen in the rear of the flame front.

Dixon discounted the conclusions of Mendeléeff and of Beketoff by showing that a dry mixture of carbon monoxide and nitrous oxide does not explode when sparked, and that dry mixtures of carbon monoxide and oxygen, whether exposed to X-rays or mixed with ozone or chlorine dioxide, are equally insensitive. In 1903 Girvan demonstrated that for a given sparking device a certain degree of desiccation is necessary to prevent explosion; while in 1914 Prof. W. M. Thornton found that for given sparking conditions the igniting current for a given medium has a minimum value.

Bone and Weston (1925) studied the minimum discharge necessary to ignite a mixture of two volumes of carbon monoxide and one volume of oxygen under different conditions of water content, and obtained a hyperbolic curve. Moreover, such a mixture, completely dried in 250 days, would withstand moderate, but not heavy, discharges. The influence of hydrogen on the carbon monoxide flame had also been examined. When much is added the characteristic appearance of the flame vanishes. In the ordinary flame of carbon monoxide in oxygen direct and indirect oxidation proceed simultaneously; so-called 'steam lines' in the spectrum may be eliminated by increasing the pressure as well as by drying. A dry carbon monoxide–oxygen mixture which failed to remain in combustion was reignited while a tension of 80,000 volts was maintained between two ring electrodes 30 cm. apart in the tube. The flame slowly reached the electrodes, suddenly accelerated, and became like that of an undried mixture.

The Tercentenary of Cinchona in Medicine.

AS a nation we are much less inclined than some of our Continental neighbours to celebrate historical events. It is therefore somewhat surprising to find that the tercentenary of the introduction of cinchona bark into European medicine (see NATURE, Nov. 29, p. 850) is being commemorated in London. Dr. H. S. Wellcome, whose interest in everything that pertains to the history or the progress of medicine is well known, has arranged at the Wellcome Historical Medical Museum, 54 Wigmore Street, London, W.1, an extremely interesting exhibition of materials, manuscripts, and literature relating to this drug. The Museum itself is rich in specimens of cinchona bark of historic interest, and possesses many rare documents and books on the subject, as well as pictures of personalities who have achieved fame as explorers of the Peruvian cinchona forests, of whom Dr. Wellcome is himself an example. To this nucleus has been added for this occasion gifts and loans from governments, learned societies, and institutions in various parts of the world, with the result that never before has such a collection of material for the study of cinchona been gathered together. The exhibition will continue open for several weeks.

Among the items of general interest may be mentioned three of the original packages of cinchona bark brought from Peru by Ruiz and Pavon on their return from the expedition sent there by Carlos III. in 1777. These are shown by H.M. the King of Spain. The Secretary of State for India has contributed five 'ne-books and the volume of original correspondence manuscript (1859–70) relating to Sir Clements Markham's expedition to Peru in connexion with the introduction of cinchona into India. No less interesting are some of the Museum's own treasures: for example, the original specimens of quinine and cinchonine isolated by Pelletier and Caventou in 1827, autograph letters of La Condamine and De Vrij, and the original permit ' issued by the Peruvian Minister of Foreign Affairs to Sir Clements Markham to enable him to carry out work in the cinchona forests. For the more technical visitor there are the extensive collections of botanical material lent by the Royal Botanical Gardens, Kew; Messrs. Howard and Sons, Ltd.; the Imperial Institute, and the Pharmaceutical Society of London. Not least important is the malaria section ' the Wellcome Medical Museum at Endsleigh Court, hich has been transferred *en bloc* to the exhibition. task of the visitor has been made easy by the llent arrangement of the exhibits, the clear bering of the specimens, and the beautifully luced catalogue.

Not content with having produced this tribute to pioneers who discovered and brought cinchona medical use, Dr. Wellcome arranged a series receptions at which addresses were given by thorities on the history and uses of the drug. At he first of these, on Monday, Dec. 8, which also served an opening ceremony, the chair was appropriately ken by Cardinal Bourne and addresses were delivered by the Ambassadors for Spain and France, whilst the Minister for Peru gave a short but interesting critical survey of the usually accepted history of cinchona. At the evening reception on the same day diplomacy and the Roman Catholic Church were still predominant, the chair being taken by the Ambassador for Holland, whilst the address was given by Cardinal B ene's able djutor, Archbishop Goodier, who co nued and xtended the criticism of the history o chona as sually written. Both critics combine demolish of the romantic story which ha een woven around the name of the Countess of Chinchon, and both declined to accept von Humboldt's statement that the natives of Peru were unaware of the virtues of cinchona.

At the receptions on Wednesday, Dec. 10, the addresses on the more technical aspects of cinchona began. In the afternoon Dr. Wellcome took the chair, whilst Sir David Prain gave the distinguished audience the fruits of his unique experience with cinchona, both as a botanist and in the capacity of a former Director of the Indian Government Cinchona Plantations, as a planter, and a quinine manufacturer. It was particularly interesting to hear this eminent authority account for the abandonment of cinchona planting in Ceylon, not by lack of enterprise or skill on the part of the British planters, but by unalterable natural causes, the chief being unsuitable soil. Sir David is also of opinion that it is unwise to devote so much attention to quinine, to the exclusion of the other cinchona alkaloids. This point was also emphasised by Prof. H. E. Armstrong, who paid a tribute to Dr. Wellcome's long continued and generous support of chemical research, and hoped that part of the energies of the various Wellcome research institutions would shortly be devoted to solving some of the many problems which the proper and economical use of cinchona still presents for solution by chemists, pharmacologists, and clinicians.

At the evening reception the principal address was given by Sir Humphry Rolleston, who provided many interesting medical sidelights on the history of cinchona and finished with an admirable summary of the therapeutics of the drug. During the present week further receptions are being given, at which the speakers will include General Sir Charles MacWatt, formerly Director-General of the Indian Medical Service; Dr. Manson-Bahr, Dr. H. H. Dale, Dr. C. M. Wenyon, and others.

University and Educational Intelligence.

BIRMINGHAM.—The increase in number of students in the Department of Oil Engineering has necessitated the erection of additional buildings adjoining the existing Oil Block. The new buildings, which are nearly complete, include a laboratory for ordinary students, a 'large-scale' laboratory, and stores. An extension of space for research will thus become available and the congested conditions under which research work is at present being carried on will be relieved. The Department of Civil Engineering has also been extended by the erection of a large Cement Laboratory.

The Council of the University has agreed to make a contribution to the funds of the Port Erin Biological Station.

LONDON.—Applications are invited for two Keddey Fletcher-Warr studentships for the promotion of post-graduate research. Each studentship will be of the annual value of not less than £250 and tenable for three years. Application forms and further particulars may be had from the Academic Registrar, University of London, South Kensington, S.W.7, to whom completed forms must be returned by Feb. 20.

A VACATION course in photogrammetry is announced to take place in the Technical-Physical Institute of the University of Jena on Mar. 16-28 next, when lectures will be given on the elements of photogrammetry, the historical development of photogrammetry, terrestrial photogrammetry, and aero-photogrammetry. Applications for the course will be received until Mar. 1 by Mr. A. Kramer, Schützenstrasse 72, Jena, Germany.

APPLICATIONS are invited for the Theresa Seessel research fellowship of Yale University, the object of which is the promotion of original research in biological studies, and the value about £300. The holder of the fellowship must reside in New Haven during the college year, October to June. Applications should be made to the Dean of the Graduate School, New Haven, Connecticut, U.S.A., before Mar. 1.

THE thirty-first annual meeting of the Science Masters' Association will be held at Birmingham, in the University buildings, on Jan. 6–9, under the presidency of Sir Charles Grant Robertson, who will deliver his presidential address on the evening of the first day of the meeting. The programme includes lectures on the lunar landscape (Mr. J. Young), complex molecular structures (Prof. W. N. Haworth), the physicist and chemist in the petroleum industry (Prof. A. W. Nash), science education of boys up to eighteen years of age (Prof. F. W. Burstall), and zoological experiments for school work (Prof. H. Munro Fox), while the Bishop of Birmingham is to give a lecture entitled "A Finite Universe?" Mr. F. Fairbrother will open a discussion on general science, and a meeting will be held with representatives of the Commission on Educational and Cultural Films. Demonstrations will be given in the University departments of science and technology, and visits to industrial works in the locality are being arranged. There will also be a trade exhibition of books and apparatus during the meeting.

Historic Natural Events.

Dec. 21, 1581. Drought.—1581 was described as the droughtiest year that any man had known. On Dec. 21 the river Trent dried up at Alrewas, Staffordshire, on account of the lack of rain.

Dec. 22, 987. Beginning of Long Frost in Western Europe.—On this date a frost began which was said to have lasted 120 days in England. In France the autumn sowings were destroyed by the cold of winter and the drought of spring.

Dec. 22, 1664. Severe Winter and Comet.—Under this date John Evelyn records that "this year I planted the lower grove next the pond at Sayes Court. It was now exceeding cold, and a hard long frosty season, and the Comet was very visible."

Dec. 22, 1894. Gale over England.—A violent westerly gale of short duration prevailed over the whole of England, Ireland, and southern Scotland during the morning, the average velocity at Fleetwood from 8.30 to 9.30 A.M. being 79 miles per hour. The storm caused much damage on land and loss of life at sea, and sea salt was carried inland as far as Birmingham (55 miles) and Masham in Yorkshire (65 miles inland).

Dec. 25, 1739. Severe Winter in England.—The winter of 1739–40 was very rigorous, though somewhat less so than 1607–8 or 1708–9. After a cold spell on Nov. 24–30, there was a warmer interval in December, but the frost commenced on Christmas Day and continued until Feb. 17. There was a second period of cold on Feb. 23–26. At the beginning of January a high wind caused great damage to the shipping in the Thames, several ships laden with corn and coal being sunk by the sheets of drifting ice; many lives were lost. Above London Bridge the Thames was completely frozen over and a 'frost fair' was held, with sports, shops, and a printing press. An ox was roasted whole on the ice, in imitation of the ceremony in 1640. A printing press was also set up on the Ouse at York. The frost was very severe on the Continent; the Zuider Zee was completely frozen, and also the sea off Ostend. A curiosity was the palace built entirely of ice on the banks of the Neva, with six cannon made entirely of ice, one of which was actually fired without being injured. The wind over western Europe was north-easterly throughout, and there was little snow.

Dec. 25, 1923. Hail.—Intense thunderstorms occurred over the Transvaal at Pretoria and to the south-eastward. Two storms struck Pretoria, the first at 6.25 P.M. and the second at 7.30 P.M. The first storm was accompanied by hailstones, some of which weighed more than five ounces. Tiled roofs were almost totally destroyed and even galvanised iron roofs were pierced; the damage to property amounted to £80,000.

Dec. 25, 1927. Snowstorm in England.—The Christmas snowstorm of 1927 is described in *British Rainfall* as "one of the worst experienced in living memory". On Dec. 25 there was snow in the Midlands but continuous rain in the south of England. In the evening the rain changed to snow, which fell heavily over south-east England during the night and throughout Dec. 26 and the following night. It was accompanied by a strong north-easterly wind, which formed heavy drifts, some of them 20 ft. deep; many main roads were completely blocked for days and some secondary roads for weeks. Motor-cars had to be abandoned, and some were completely buried in snow. Many villages were practically cut off from the world, and a few had to be provisioned by parcels dropped from aeroplanes. On Jan. 21, 1928, six or seven feet of snow still lay in some of the Hampshire roads. The storm was most severe and the snow deepest on Dartmoor, in the Alton-Basingstoke district, and along the North Downs.

Dec. 26-30, 1906. Snowstorms in British Isles.—Snow fell heavily over the greater part of the British Isles during these five days. The depth was greatest in the south of Scotland, where numerous trains were snowed up; Aberdeen was isolated for three days, and near Arbroath a railway collision cost many lives. In Ireland the snowfall was probably the greatest on record for depth and intensity. During the same week heavy snow fell also in eastern Europe, accompanied by a high wind which caused it to accumulate in deep drifts.

Dec. 27, 1813. London Fog.—It is recorded in the *Annals of Philosophy* that between Dec. 27, 1813, and Jan. 2, 1814, "a most extraordinary fog prevailed in London, and seems to have extended a great many miles round in every direction. It was frequently so thick that it was impossible to see across the street, candles were burnt in most of the shops and counting houses all day long. This fog condensed upon the grass, the trees, and every wooden or iron railings. The grass was covered with a coating of snow (condensed fog) at least half an inch thick. Below the trees in St. James's Park there lay a bed of snow an inch thick at least, which had fallen from them. In London the thickness of the fog was still further increased by the smoke of the city; so much so, that it produced a very sensible effect on the eyes, and the coal tar varnish might be distinctly perceived by the smell. But at a distance from town, though there was no smoke, the fog was very thick, not a breath of wind was perceptible during the whole week."

ERRATUM.

Dec. 9-11, 1672. Glazed Frost in Somerset.—The record of this phenomenon in the abridged edition of the *Philosophical Transactions*, vol. 2, p. 37, implies that the year was 1671, but Mr. C. E. Britton, of the Meteorological Office, New Ranges, Shoeburyness, from a study of the unabridged edition, states that the correct date should be 1672.

Societies and Academies.

LONDON.

Physical Society, Nov. 7.—W. N. Bond: Turbulent flow through tubes. The experimental methods included (*a*) an aural method; (*b*) photography of the motion of a deflected vane; and (*c*) injection of colour-streams about half-way along the tube. Intermittent turbulence was investigated at speeds near the critical speed, and measurements of the critical speed were made. The velocity parallel to the tube-axis is sometimes almost uniform momentarily over the transverse section. No trace was found of a simple frequency, but evidence was obtained of a predominant wave-length in the turbulent motion at the critical speed. Both these observations seem to agree with the approximate theory given by Heisenberg for flow between a pair of parallel planes.

Geological Society, Nov. 19. A. Brammall: The Dartmoor granites: their genetic relationships (with 80 analyses by Dr. H. F. Harwood and assistants). This complex of differentiated types comprises an 'early' granite suite (sodi-potassic) and a 'late' suite (potassic). They enclose relics of an older differentiated suite (sodic) ranging from granodiorites to granites (with porphyries) and including terms which approximate to Rosenbusch's 'average alkali-granite'. These cognate inclusions are distinguished from hornfelsed xenoliths (shales and diabases). Biotites and orthoclase-phenocrysts 'vary' in the same sense as the granites themselves. The variation-curves for the whole complex show no feature that is inconsistent with a basaltic parentage. Contrary to expectations based on phase-equilibrium, the phenocrysts of the older main granites contain in solid solution a norm-plagioclase which is more albitic than the average for the containing granites. This anomaly (with some others) and the further fact that these coarse granites are the richest in accessory species suggest the effectiveness of crystal-accumulation, as postulated by Bowen. Contamination is general; hybrids are described.

Linnean Society, Nov. 20. R. Gopala Aiyer: An account of the development and breeding habits of a brackish-water polychaet worm of the genus *Marphysa*. A species of *Marphysa* lives in the mouth of the Adyar River (Madras) and the neighbouring backwater. The mouth of the Adyar is usually closed, and the water brackish. The spawn of the worm is found mainly from February to September as jelly-like masses in which the tiny black eggs are embedded. The development of the eggs was observed in the laboratory over a period of eight months. There is no free-swimming stage. The larvæ sink to the bottom and begin a creeping existence. The creeping life is given up as new segments are added, and the tiny worms construct small tubes formed mainly of organic debris cemented together by mucus. Development takes nearly six months.

Society of Public Analysts, Dec. 3.—G. Middleton: A storage and delivery apparatus for antimony chloride solution and other corrosive reagents. Antimony chloride solution is forced upwards by means of a compression rubber bulb into a tube fitted inside the reagent bottle, whence it passes into an external measuring tube, delivering 2 c.c. into the tintometer cell. The ground-glass joints are constructed in such a manner that the reagent does not come in contact with them.—**G. Middleton and F. C. Hymas**: Tests for impurities in ether (2 and 3). The tests recommended for official adoption are: For acetaldehyde, modified Schiff's reagent, made by the addition of 0·1 per cent pyrogallol; and for acetone, the vanillin test of the Dutch Pharmacopœia.—**Norman Evers**: The determination of small quantities of calcium in magnesium salts. Dissolve the required weight of the magnesium salt in 25 c.c. of 20 per cent sulphuric acid, and add 50 c.c. of 95 per cent (by vol.) alcohol. Mix thoroughly and leave overnight. Filter on a Gooch crucible and wash with 200 c.c. of a mixture of 2 volumes of 95 per cent alcohol and 1 volume of 20 per cent sulphuric acid. Ignite and weigh as $CaSO_4$. The results obtained have a tendency to be slightly low. The method may also be applied to solutions containing phosphates, iron, etc. **P. K. Bose**: A new method for the detection of nitro-groups in organic compounds. The method, which is applicable to all poly-nitro organic compounds, is based on the hydrolytic dissociation of the compound by means of potassium hydroxide, and the identification of the resulting nitrous acid by means of the Griess-Ilosvay reagent.

PARIS.

Academy of Sciences, Nov. 17.—A. Lacroix: New observations on the tectites of Indo-China. Tectites have been found in large numbers over a distance of 1300 kilometres in Indo-China. Their chemical composition is constant. The possible origin of these tectites is discussed: volcanic origin, genesis in the place found, are both impossible, and a cosmic origin appears probable.—**André Blondel**: The practical magnetic units.—**Georges Claude**: Concerning a communication of M. Raveau. **R. Nasini**: The discovery of boric acid in the glaze of Arezzo vases. The presence of borax in these Roman glazes of the first century has been suggested, but not proved. By the analyses of authenticated specimens it is now established that this red glaze contains boric acid, not as occasional traces but as a true constituent. Charles Porcher was elected *Correspondant* for the Section of Rural Economy in succession to the late Ulysse Gayon.—**E. Halphen**: The extension of Chasles's theorem to space.—**N. Achieser**: The asymptotic properties of some polynomials. **A Kolmogoroff**: The law of large numbers. **Mlle. Marie Charpentier**: The existence of Peano points of a differential equation of the first order.—**Rolf Nevanlinna**: A class of transcendental functions. **J. Delsarte**: The determination of the Taylor coefficients of a probability function the moments of which are known.—**Jos. Kaucký**: Remarks on the note of M. V. Romanovsky. The discrete chains of Markoff.—**Julius Wolff**: The angular derivative.—**Couffignal**: A new calculating machine.—**D'Ocagne**: Remarks on the preceding note.—**J. Ph. Lagrula**: The position error of the centre of dependences at the interior of a triangle of reference, when the homology is assimilated to linear homography. **James Basset**: An apparatus for experimenting on gases at ultra-pressures of 6000 kgm. per square centimetre. Description with a photograph and two diagrams of the apparatus.—**E. Brylinski**: A system of mechanical, electrical, and magnetic units.—**Panc-Tcheng Kao**: The relaxation oscillations produced by an oscillator with piezo-electric quartz.—**R. Weil**: New observations on quartz.—**A. Dauvillier**: The X-ray spectra of gases. The *K* series of krypton and xenon.—**P. Lebeau and A. Damiens**: The action of fluorine upon wood charcoal. The boiling point and melting point of carbon tetrafluoride. The gas obtained by the action of fluorine upon wood charcoal, after freeing from oxygen and moisture, is liquefied by cooling to $-190°$ C. By fractional distillation of this liquid, pure carbon tetrafluoride has been prepared, with a boiling point of $-126°$ C. and melting point $-191°$ C. From the heavier fractions two other gases have been isolated, hexafluor ethane, C_2F_6, and octafluor propane, C_3F_8, and these are being further studied.—**M. Paić**:

The X-ray study of the products obtained by the action of the halogen acids on the mercuric sulphates. Fusion diagram of the system HgI_2-$HgSO_4$. - **Sou Phou Ti**: The action of ethylmagnesium bromide on *N*-diethylmonochloracetamide. This reaction took an unexpected course, the main product being an amino-alcohol, probably $Et_2N \cdot CEt_2 \cdot CH_2OH$. A trace of diethylacetaldehyde was also isolated.—**J. Décombe**: The *N*-alkylation of the β-amino-ethers.—**Mlle. S. Grateau**: A new method of preparing the δ-ketonic esters. The Friedel and Crafts reaction applied to the chloride ester of adipic acid gives an excellent yield of ethyl δ-benzoylvalerate, and the reduction of this ester leads to phenylcaproic acid. The method appears to be capable of general application.—**Frèrejacque**: A catalyst for the autoxidation of uric acid. In presence of activated carbon, uric acid is completely oxidised in alkaline solution by oxygen, giving a mixture of allantoin and oxonamide.—**A. Travers** and **Franquin**: The extraction of the bases from the condensation liquors of primary tar. **Maurice Blumenthal**: The structure of the penibetic chain between Antequera and Loja (Andalusia). - **Jacques Bourcart**: An attempt at the co-ordination of the observations on the stratigraphy of the Atlantic slope of the Djebalas peninsula (Northern Morocco).— **Mlle. Eliane Basse**: Geological observations on the fossil-bearing secondary formation outcropping between Onilahy and Fiherenana (South-West Madagascar).—**Albert Nodon**: The humming of aerial lines and atmospheric disturbances. The methodical study of the humming of conducting wires, assisted by an amplifying arrangement, can give information valuable for weather forecasts.—**J. Bosler**: The relations between magnetic storms and the earth currents.— **J. Magrou** and **Mme. M. Magrou**: Actions exerted at a distance on the fertilised egg, the sperm, and the virgin egg of the sea-urchin, *Paracentrotus lividus*.— **H. Bordier** and **C. Boisson**: A new application of d'Arsonvalisation: hydrodiathermotherapy. **F. Rosenbusch**: A disease of Paraguay cattle, similar to paralytic rabies.

LENINGRAD.

Academy of Sciences, *Comptes rendus*, No. 16, 1930.—**S. Bernstein**: Some remarks on the polynoms of the minimum deviation with whole coefficients.— **V. Kistiakovskij**: The problem of metastable flotation.— **N. Willams**: The action of the nitric acid on the primary tetrahydro-α-furfurilamine. - **I. Kurbatov**: Conditions of growth of crystals of slightly soluble substances. **B. Licharev**: Two new representatives of the family Productidæ from the Lower Permian of North Caucasus. Descriptions of *Loczyella* (?) *parvula*, sp. n., and *Pectenoproductus proprius*, gen. and sp. n.

Comptes rendus, No. 17, 1930.—**P. Lazarev**: Action of certain substances on the nervous centres. General theoretical considerations.—**P. Lazarev** and **A. Dubinskaja-Voskresenskaja**: Objective studies of nervous centres in persons suffering from *paralysis progressiva*, after the application of salvarsan and of X-rays. Determinations of the increase in the sensibility of eyes supply a method for observing objectively the action of X-rays and of salvarsan. - **P. Lazarev** and **L. Kuper**: Action of acoustic excitations on the sensibility of the eye. The peripheral sensibility decreases under the influence of sounds. —**N. Demjanov**: Action of nitric anhydride on the ethylenic hydrocarbons.— **I. Kurbatov**: The proportions of some active elements in the dispersion rocks of Tuia-Mouiun. - **V. Gromova**: The type of *Bison priscus* Bojanus. A specimen from Siberia in the collection of the Zoological Museum of the Academy is redescribed as the type. **N. Jakovlev**: The discovery of the anal proboscis in the genus *Cupressocrinus*.—**A. Vinogradov**: Vanadium in marine organisms. The concentration of vanadium in the ascidian *Phallusia obliqua* may be up to 0·0302 per cent of the live weight.—**P. Schmidt** and **G. Lindberg**: A new Japanese fish, *Paracanthochaetodon modestus*, gen. and sp. n.

PRAGUE.

Czech (Bohemian) Academy of Arts and Sciences (second class, Natural Sciences and Medicine), Oct. 17. —**J. Wolf**: The origin of fibrillar collagenic sols. Fibrillar sols of the synovia.—**L. Borovanský**: A contribution to the study of growth of organs during the fœtal period.—**V. Hovorka**: Reaction of iodic acid with phosphorous and hypophosphorous acid. In acidic medium, hypophosphorous acid is easily oxidised to phosphorous acid; in alkaline solution iodates are reduced only by hypophosphites. In presence of argentous and mercuric salts the reactions are complicated.—**V. Kořinek**: Quadratic bodies of quaternion orbits. —**J. Koutský**: A study of asymptotic transformations of undevelopable surfaces in projective S_3. - **R. Lukeš**: The action of Grignard's agent on *N*-methyl-pyrrolidon. Grignard's agent of methyl-, ethyl-, *n*-propyl-, and phenyl-bromides acting on *N*-methyl-pyrrolidon yielded 1-methyl-2 alkyl-Δ_2-pyrrolines, which were isolated as perchlorates, and the corresponding 1-methyl-2·2 di-alkyl-pyrrolidines. The aromatic agent gave 1-methyl-2-phenyl-Δ_2-pyrroline. - **V. Prelog**: The sapogenin of beetroot. The oxidation of sapogenin ($C_{31}H_{50}O_3$) by chromic acid yielded a ketonic acid, $C_{31}H_{48}O_3$, giving a methylester, a semicarbazone, and a keto-hydroxy lactone, $C_{31}H_{46}O_4$. The carboxyl is bound to a tertiary carbon atom and the substance contains inert double-linkages. - **K. Šimek**: The graphical solution of reactions and axial forces for special plain systems of poles. - **J. Petrbok**: Pleistocene molluscs of the Danube terrace near Russe in Bulgaria.—**V. Posejpal**: A third contribution to the study of universal ether. From his conception of particles of ether, the radius, r, of which should be identical with that of an electron, the author deduces the diffusion coefficient σ/ρ of hydrogen for very hard γ-rays as $\frac{\sigma}{\rho}$ [illegible] m_H [illegible], where m_H is the absolute mass of a hydrogen atom. The radius of the ether particle thus calculated agrees well with the value derived for the radius of the electron from the electro-magnetic theory of mass. **J. M. Jaeger**: Molecular configuration and optical activity. Methods, results, and problems of precise modern measurements of high temperatures. Constitution and structure of ultramarine.—**C. Purkyně**: The waterfall of river Zambezi.

Nov. 14.- **E. Votoček**: Osazonogenic groups. From original experiments and literature the osazonogenic grouping is shown to be more general, extending to groups like $-CO.CH_2Cl$, $-CO.CHCl_2$, $C-CHCl-CO-$, and many others.—**F. Valentin**: A new form of the two rhamnite antipodes. The two optical isomerides, rhamnite trihydrates, $C_6H_{14}O_5.3H_2O$, are enantiomorphous, according to Pasteur's rule. **J. Babička**: The determination of proteins by means of electrolysis with the dropping mercury cathode. In the presence of ammonium salts solutions containing soluble proteins (ovo-albumin, serum-albumin, hæmoglobin, phyto-albumin) the electrolytic current-voltage curves, registered polarographically, show an electro-reduction at $-1·5$, $-1·7$ volt. The increase of current at this cathodic potential is proportional to the amount of soluble protein. Qualitative and quantitative estimation of albumins is thereby possible.—**R. Nováček**: Linnéit from the mine Prago at Kladno.— **V. Tůma**: On the process of closing umbilical blood vessels during human birth.—**J. Matiegka** and **J. Malý**: The bodily remains of Karel Havlíček Borovský.

Official Publications Received.

BRITISH.

Mathematical Notes: a Review of Elementary Mathematics and Science. Edited by William Arthur. No. 26, October. Pp. xxii. (Edinburgh: Edinburgh Mathematical Society.)

The Scientific Proceedings of the Royal Dublin Society. Vol. 19 (N.S.), Nos. 40-47. 40: The Nitration of Substituted Diaryl Ethers:—Phenyl-p-Tolyl Ether, by Joseph Reilly, P. J. Drumm and T. Gray; 41: Study of the Polysaccharides, Part 3: Acetamide as a Polysaccharide Solvent, by J. Reilly, Dr. Reinhold Wolter and P. P. Donovan; 42: Report of the Irish Radium Committee for the Year 1929, including Reports by Oliver Chance, Andrew Charles, Oswald J. Murphy, Dr. Walter C. Stevenson, C. M. Taylor, Josephine Walsh; 43: The Raised Beaches of the East Coast of Ireland, by C. P. Martin; 44: *Paradomyces hibernicum*—New Species, by C. V. E. Kennelly and M. Grimes; 45: Photo-electric Measurements of Illumination in relation to Plant Distribution, Part 3: Certain Spruce, Larch, Oak and Holm Oak Woods, by Dr. W. R. G. Atkins and Florence A. Stanbury; 46: The Distribution of Pasture Plants in relation to Soil Acidity and other Factors, by Dr. W. R. G. Atkins and E. Wyllie Fenton; 47: A Study of Fungi found in Butter, by M. Grimes and V. C. E. Kennelly and H. A. Cummins. Pp. 461-569+plates 19-23. (Dublin: Hodges, Figgis and Co.; London: Williams and Norgate, Ltd.) 8s.

Proceedings of the Royal Society. Series A, Vol. 129, No. A811, November 3. Pp. 411-698+xxxviii. (London: Harrison and Sons, Ltd.) 15s.

Proceedings of the Malacological Society of London. Edited by R. Winckworth. Vol. 19, Part 3, November. Pp. 83-155+plates 9-17. (London: Dulau and Co., Ltd.) 10s. net.

Transactions of the Edinburgh Geological Society. Vol. 12, Part 3. Pp. 289-304. (Edinburgh.) 1s.

Report on the Administration of the Museum and Public Gardens during 1104 M.E. Pp. 15. (Trivandrum.)

Conference of Directors of Far Eastern Weather Services, Hong Kong, 1930. Report of Proceedings, with Appendices and List of Delegates. Pp. ii+69. (Hong Kong: Royal Observatory.)

Department of Agriculture, Straits Settlements and Federated Malay States. Scientific Series No. 2: Investigations on Panama Disease in Malaya. By F. S. Ward. Pp. iii+26+4 plates. 1 dollar. Scientific Notes No. 3: An Historical Note on *Pirathalia rubicena* Walk. (The Greater Coconut Spike Moth) and its three Parasites in Malaya, by G. H. Corbett; Preliminary Observations on *Sogata* spp. Pests of Padi, by N. C. E. Miller and H. T. Pagden. Pp. 14. 50 cents. (Kuala Lumpur.)

Report of the Botanical Survey of India for 1928-29. Pp. 9. (Calcutta.)

Air Ministry: Aeronautical Research Committee. Reports and Memoranda. No. 1328 (E. 38): Performance of a Compression Ignition Unit with Reduced Intake and Exhaust Pressures. By P. H. Stokes. (I.C.E. 44 A. and B.) Pp. 20+21 plates. 1s. 6d. net. No. 1332 (Ae. 461): Comparative Handling Tests of three Bristol Fighter Aircraft with different Types of Slots. By Flight-Lieut. C. E. Maitland and Flight-Lieut. J. H. C. Wake. (S. and C. 331.) Pp. 8+9 plates. 9d. net. No. 1335 (Ae. 466): Photographic Records of Flow in the Boundary Layer. By L. F. G. Simmons and N. S. Dewey. (T. 2958.) Pp. 9+6 plates. 1s. net. No. 1336 (E. 40): The Application of Dimensional Relationships to Air Compressors, with Special Reference to the Variation of Performance with Inlet Conditions. By R. S. Capon and G. V. Brooke. (I.C.E. 762.) Pp. 22+9 plates. 1s. 3d. net. (London: H.M. Stationery Office.)

University of Cambridge: Solar Physics Observatory. Eighteenth Annual Report of the Director of the Solar Physics Observatory to the Solar Physics Committee, 1929 August 1-1930 July 31. Pp. 5. (Cambridge.)

The Association of Engineering and Shipbuilding Draughtsmen Diary 1931. Pp. 110+Diary. (London: The Draughtsman Publishing Co., Ltd.)

Public Library, Museum and Art Gallery of South Australia. Records of the South Australian Museum, Vol. 4, No. 2. Pp. 145-273. (Adelaide.) 10s. 6d.

Proceedings of the Royal Society of Edinburgh, Session 1929-1930. Vol. 50, Part 3, No. 21: The Climate during the Pleistocene Period. By Dr. G. C. Simpson. Pp. 262-296. 3s. Vol. 50, Part 3, No. 22: The Metabolism of the Frog's Isolated Heart. By Prof. A. J. Clark, Dr. C. P. Stewart and R. Gaddie. Pp. 297-303. 9d. Vol. 50, Part 3, No. 23: On some Persymmetric Determinants. By J. Geronimus. Pp. 304-309. 9d. Vol. 50, Part 3, No. 24: The General Form of the Orthogonal Polynomials for Simple Series, with Proofs of their Simple Properties. By F. E. Allan. Pp. 310-320. 1s. (Edinburgh: Robert Grant and Son; London: Williams and Norgate, Ltd.)

The British Institute of Radiology, incorporated with the Röntgen Society. Year Book 1930. Pp. 72. (London.)

The Journal of the Institution of Electrical Engineers. Edited by P. F. Rowell. Vol. 68, No. 407, November. Pp. 1369-1539+xxxii. (London: E. and F. N. Spon, Ltd.) 10s. 6d.

Journal of the Royal Society of Western Australia. Vol. 15, 1928-1929. Pp. xlv+131. (Perth.) 35s.

Ministry of Transport and Ministry of Agriculture and Fisheries: Joint Committee on Damage to Fisheries. Detailed Biological and Chemical Reports on Tars used for Road-Surfacing. Pp. 171. (London: H.M. Stationery Office.) 2s. 6d. net.

New Zealand: Department of Lands and Survey. Scenery-Preservation: Report for the Year ended 31st March 1930, together with Statement of Accounts and Schedule of Lands acquired and reserved during the Year under the Scenery Preservation Act. Pp. 30+8 plates. (Wellington, N.Z.: W. A. G. Skinner.)

New Zealand. Tongariro National Park: Annual Report of the Board. Pp. 7. (Wellington, N.Z.: W. A. G. Skinner.) 6d.

Trinidad and Tobago. Minutes and Proceedings of the Froghopper Investigation Committee. Part 9. Pp. 81-192. (Trinidad, B.W.I.: Government Printing Office, Port-of-Spain.)

The Royal Technical College, Glasgow. Annual Report on the One Hundred and Thirty-fourth Session adopted at the Annual Meeting of Governors held on the 21st October 1930. Pp. 79. (Glasgow.)

Canada. Department of Mines: Mines Branch. Investigations of Fuels and Fuel Testing (Testing and Research Laboratories) 1928. (No. 712.) Pp. ii+71+2 plates. (Ottawa: F. A. Acland.)

Tide Tables for the Eastern Coasts of Canada for the Year 1931: including the River and Gulf of St. Lawrence, the Atlantic Coast, the Bay of Fundy, Northumberland and Cabot Straits, and Information on Currents; in addition Tide Tables for New York and Boston, U.S.A. Issued by the Tidal and Current Survey Division of the Hydrographic Service, in the Department of Marine and Fisheries of the Dominion of Canada. Thirty-fifth Year of Issue. Pp. 92. (Ottawa: F. A. Acland.)

Air Ministry: Aeronautical Research Committee. Reports and Memoranda. No. 1303 (E. 39): Torsional Vibration of Crankshafts Beardmore 'Tornado' Airship Engine Investigations. By B. C. Carter and N. S. Muir. (T.V.C. 44 and 50.) Pp. 56+10 plates. (London: H.M. Stationery Office.) 3s. net.

Memoirs of the Geological Survey of India. Vol. 56: The Jharia Coal Field. By Dr. C. S. Fox. Pp. vi+255+vii+21 plates. (Calcutta: Government of India Central Publication Branch.) 8.12 rupees; 14s.

Records of the Geological Survey of India. Vol. 63, Part 3. Pp. 281-377. (Calcutta: Government of India Central Publication Branch.) 2.12 rupees; 5s.

The British Mycological Society. Transactions. Edited by Carleton Rea and J. Ramsbottom. Vol. 15, Parts 1 and 2, 15 November. Pp. 192. (London: Cambridge University Press.) 15s.

Tide Tables for the Pacific Coast of Canada for the Year 1931: including Fuca Strait, the Strait of Georgia and the Northern Coast, with Data for Slack Water in the Navigable Passes and Narrows and Information on Currents, also Tide Tables for the U.S. Ports of Seattle and Port Townsend. Issued by the Tidal and Current Survey Division of the Hydrographic Service, in the Department of Marine and Fisheries of the Dominion of Canada. Thirty-first Year of Issue. Pp. 80. (Ottawa: F. A. Acland.)

Department of Scientific and Industrial Research. Index to the Literature of Food Investigation. Vol. 2, No. 2, September. Compiled by Agnes Elisabeth Glennie. Pp. iv+89. (London: H.M. Stationery Office.) 2s. net.

London University Guide and University Correspondence College Calendar, 1931-1932. Pp. 247. (Cambridge and London: University Correspondence College.) 2s. 6d.

The North of Scotland College of Agriculture. Report on the Work of the North of Scotland College for the Year 1929-30. Pp. 30. (Aberdeen.)

Summary and Progress of the Geological Survey of Great Britain and the Museum of Practical Geology for the Year 1929. Part 3. Pp. iv+89+8 plates. (London: H.M. Stationery Office.) 2s. 6d. net.

Report of the Department of Industries, Madras, for the Year ending 31st March 1930. Pp. vi+122. (Madras: Government Press.) 12 annas.

The University of Manchester: The Manchester Museum. Museum Publication 99: Report of the Museum Committee for the Year 1929-30. Pp. 27. 6d. net. Museum Publication 100. Notes from the Manchester Museum, No. 33: Three Manchester Botanists. Leopold Hartley Grindon, Charles Bailey, James Cosmo Melvill. (Course of Museum Lectures delivered November-December 1929.) By Prof. F. E. Weiss. Pp. 20+3 plates. 2s. 6d. (Manchester.)

Jubilee Congress of the Folk Lore Society, Sept. 19-Sept. 25, 1928. Papers and Transactions. Pp. 319+5 plates. (London: William Glaisher, Ltd.) 21s. net.

Board of Education. Report on the Science Museum for the Year 1929. Pp. 27. (London: H.M. Stationery Office.) 6d. net.

North-East Coast Institution of Engineers and Shipbuilders. List of Members, 1st August 1930. Pp. 48. (Newcastle-upon-Tyne.)

Department of Scientific and Industrial Research. Building Science Abstracts. Vol. 3 (New Series), No. 10, October. Abstracts Nos. 1854-2038. Pp. 341-378. (London: H.M. Stationery Office.) 9d. net.

Royal Agricultural Society of England. Agricultural Research in 1929. Pp. viii+182. (London: John Murray.) 1s.

FOREIGN.

The Rockefeller Foundation. Annual Report, 1929. Pp. viii+402. (New York City.)

Bulletin of the American Museum of Natural History. Vol. 60: The Birds of Matto Grosso, Brazil; a Report on the Birds secured by the Roosevelt Rondon Expedition. By Elsie M. B. Naumburg, with Field Notes by George K. Cherrie. Pp. vii+432+17 plates. (New York City.)

Proceedings of the United States National Museum. Vol. 78, Art. 9: American Two-winged Flies of the Genus *Stylogaster* Macquart. By J. M. Aldrich. (No. 2852.) Pp. 27. (Washington, D.C.: Government Printing Office.)

U.S. Department of Agriculture. Miscellaneous Publication No. 86: Outlines for Studies of Mammalian Life Histories. By Walter P. Taylor. Pp. 12. (Washington, D.C.: Government Printing Office.) 5 cents.

Scientific Publications of the Cleveland Museum of Natural History. Vol. 1, No. 3: A new Genus of African Starlings. By Harry C. Oberholser. Pp. 81-82+plate 17. (Cleveland, Ohio.)

Ministry of Public Works, Egypt: Physical Department. Further Experiments on the Discharge of Models of Sluices. By Dr. H. E. Hurst. (Physical Department Paper No. 25.) Pp. iii+23+19 plates. (Cairo: Government Press.) 10 P.T.

Suomen Geodeettisen Laitoksen Julkaisuja: Veröffentlichungen des Finnischen Geodätischen Institutes. No. 13: Relative Bestimmungen der Schwerkraft in Finnland in den Jahren 1926-1929. Von U. Pesonen. Pp. 168. No. 14: Anwendung der Lichtinterferenz bei Basismessungen. Von Prof. Y. Väisälä. Pp. 47. (Helsinki.)

United States Department of Agriculture: Weather Bureau. Monthly Weather Review, Supplement No. 34: The Daily, Monthly and Annual Normals of Precipitation in the United States, based on the 50-Year Period, 1878-1927 inclusive. By P. C. Day. Pp. 101. (Washington, D.C.: Government Printing Office.) 35 cents.

The Museum of the Brooklyn Institute of Arts and Sciences. Science Bulletin, Vol. 4, No. 1: Maya Dates and what they Reveal; a Re-examination of the Evidence in Correlation between Central American and European Time Counts. By Herbert J. Spinden. Pp. 111. (Brooklyn, N.Y.)

State of Illinois. Department of Registration and Education: Division of the Natural History Survey. Classified List of Publications available for Exchange and Distribution, including the Publications of the State Entomologist's Office and the State Laboratory of Natural History. Pp. 30. Bulletin, Vol. 18, Art. 3: Epidemic Diseases of Fruit Trees in Illinois, 1922-1928. By L. R. Tehon and Gilbert L. Stout. Pp. 411-502. Bulletin, Vol. 19, Art. 1: The Fishes of Champaign County: a Study of the Distribution and Abundance of Fishes in Small Streams. By David H. Thompson and Francis D. Hunt. Pp. 101. Bulletin, Vol. 19, Article 2: Records of Spring Migration of Birds at Urbana, Illinois, 1903-1922. By Frank Smith. Pp. 103-117. (Urbana, Ill.: State Natural History Survey.)

Cornell University Agricultural Experiment Station. Bulletin 507: Motor Trucks on New York Farms. By C. W. Gilbert. Pp. 55. Memoir 132: Biochemistry and Biophysics of the Developing Hen's Egg. 1: Influence of Humidity. By Alexis L. Romanoff. Pp. 27. (Ithaca, N.Y.)

Proceedings of the United States National Museum. Vol. 77, Art. 19: Notes on the Rhinotragine Beetles of the Family Cerambycidae, with Descriptions of New Species. By W. S. Fisher. (No. 2842.) Pp. 20. Vol. 77, Art. 20: The Taxonomy and Host Relationships of the Biting Lice of the Genera Dennyus and Eureum, including the Descriptions of a New Genus, Subgenus and four New Species. By H. E. Ewing. (No. 2843.) Pp. 16. (Washington, D.C.: Government Printing Office.)

Publikationer fra det Danske Meteorologiske Institut. Communications magnétiques, etc. No. 11: Le variometre de Copenhague, par D. la Cour et Viggo Laursen; No. 12: On the Scale Value and the Base Value of the H-Variometer, by V. H. Ryd. Pp. 11+11. (København: G. E. C. Gad.)

Publications de l'Observatoire Astronomique de l'Université de Belgrade. Tome 3: Annuaire pour l'an 1931. Rédigé par V. V. Michkovitch. Pp. 146+3 planches. (Belgrade.)

Scientific Papers of the Institute of Physical and Chemical Research. Nos. 271-273: A Study on the Decomposition of Potassium Ferrocyanide and of Potassium Ferricyanide by the Autoclave Treatment, by Tominosuke Katsurai and Tokunosuke Watanabe; Researches on the Cutting Force, 2: Cutting Action of Planing Tool, by Makoto Ōkoshi; Grain-Growth of Marble (Abridgement), by Masawo Kuroda. Pp. 189-227. (Tokyo: Iwanami Shoten.) 75 sen.

Mount Wilson Catalogue of Photographic Magnitudes in Selected Areas 1-139. By F. H. Seares, J. C. Kapteyn and P. J. van Rhijn, assisted by Mary C. Joyner and Myrtle L. Richmond. (Papers of the Mount Wilson Observatory, Vol. 4.) (Publication No. 402.) Pp. 1+276. (Washington, D.C.: Carnegie Institution.) 8.00 dollars.

Contributions to Palaeontology from Carnegie Institution of Washington. 1: A Neocene Erosion Surface in Central Oregon, by John P. Buwalda; 2: The Dalles and Hood River Formations, and the Columbus River Gorge, by John P. Buwalda and Bernard N. Moore; 3: Oreodonts from the Sespe Deposits of South Mountain, Ventura County, California, by Chester Stock; 4: Carnivora New to the Mascall Miocene Fauna of Eastern Oregon, by Chester Stock; 5: Capromeryx minor Taylor from the McKittrick Pleistocene, California, by Eustace L. Furlong; 6: A Tertiary Vertebrate Fauna from the Upper Cuyama Drainage Basin, California, by C. Lewis Gazin; 7: A Tertiary Mammalian Fauna from the Mint Canyon Formation of Southern California, by John H. Maxson. (Publication No. 404.) Pp. iii+112+8 plates. (Washington, D.C.: Carnegie Institution.) 2.25 dollars.

Contributions to Embryology. Vol. 21,

Structure of Thyroid Gland in Man, by W. F. Reinhoff, Jr.; 124: The Age Factor in Grafts, by Vera Danchakoff and V. E. Danchakoff; 125: The Early Embryology of the Rabbit, by P. W. Gregory. (Publication No. 407.) Pp. iii+168+29 plates. (Washington, D.C.: Carnegie Institution.) 3.75 dollars.

Thermodynamic Relations in Multi-Component Systems. By Roy W. Goranson. (Publication No. 408.) Pp. xvii+329. (Washington, D.C.: Carnegie Institution.) 6.00 dollars.

Leonardo da Vinci, the Anatomist (1452-1519). By Prof. J. Playfair McMurrich. (Published for the Carnegie Institution.) (Publication No. 411.) Pp. xx+265+72 plates. (Baltimore, Md.: Williams and Wilkins Co.) 6.00 dollars.

Report of the Aeronautical Research Institute, Tōkyō Imperial University. No. 63: The Attempted Take-off of the "City of Tacoma" for the Trans-Pacific Flight at Kasumigaura, Japan. By Taituro Ogawa. Pp. 219-259+2 plates. (Tōkyō: Koseikai Publishing House.) 0.16 yen.

Proceedings of the United States National Museum. Vol. 77, Art. 12: Birds from the Small Islands off the Northeast Coast of Dutch Borneo. By J. H. Riley. (No. 2835.) Pp. 23+1 plate. (Washington, D.C.: Government Printing Office.)

U.S. Department of Agriculture. Circular No. 139: Method and Procedure of Soil Analysis used in the Division of Soil Chemistry and Physics. By W. O. Robinson. Pp. 20. (Washington, D.C.: Government Printing Office.) 5 cents.

Pp. 397-528. (Philadelphia.)

Ministère de l'Instruction publique et des Beaux-Arts. Enquêtes et documents relatifs à l'enseignement supérieur. 124: Rapports sur les Observatoires astronomiques de province et les Observatoires et Institut de Physique du Globe, année 1928. Pp. 115. (Paris: Imprimerie Nationale.)

Mémoires du Musée Royal d'Histoire Naturelle de Belgique. Mémoire No. 45: Hydromedusae collected in the South-Western Part of the North Sea and in the Eastern Part of the Channel in 1903-1914. By P. L. Kramp. Pp. 55. (Bruxelles.)

An Album of the Groups in the Verney-Faunthorpe Hall of South Asiatic Mammals of the American Museum of Natural History. Pp. 28+24 plates. (New York City.)

U.S. Department of Commerce: Bureau of Standards. Bureau of Standards Journal of Research. Vol. 5, No. 4, October. Pp. 781-9[illegible]. (Washington, D.C.: Government Printing Office.)

Reprint and Circular Series of the National Research Council. No. 94: Eighth Report of the Committee on Contact Catalysis. By J. C. W. Frazer. Pp. 51. 50 cents. No. 95: Doctorates conferred in the Sciences by American Universities, 1929-1930. Compiled by Callie Hull and Clarence J. West. Pp. 49. 50 cents. No. 96: Second Report of the Committee on Photochemistry. By Hugh S. Taylor. Pp. 4[illegible]. 50 cents. (Washington, D.C.: National Academy of Sciences.)

State of California: Division of Fish and Game. Fish Bulletin No. 23: Success of the Purse Seine Boat in the Sardine Fishery at Monterey, California (1929-1930 Fishing Season). By J. B. Phillips. Pp. 30. Free. Fish Bulletin No. 24: An Analysis of the Catch Statistics of the Striped Bass (*Roccus lineatus*) Fishery of California. By J. A. Craig. Pp. 4[illegible]. Free. Fish Bulletin No. 25: Fishing areas along the California Coast for the Sardine (*Sardinia caerulea*). By the California State Fisheries Laboratory. Pp. 46. Free. Fish Bulletin No. 26: Seasonal Changes in the Daily Average Length of the California Sardine (*Sardinia caerulea*). By Frances N. Clark. Pp. 22. Free. (Terminal Island, Calif.: California State Fisheries Laboratory.)

Annual Report of the Board of Regents of the Smithsonian Institution showing the Operations, Expenditures and Condition of the Institution for the Year ending June 30, 1929. (Publication 3034.) Pp. xiii+62[illegible]+91 plates. (Washington, D.C.: Government Printing Office.) 1.7[illegible] dollars.

Diary of Societies.

FRIDAY, DECEMBER 19.

LONDON SOCIETY (at Royal Society of Arts), at 5.—Prof. S. D. Adshead: South Essex: Its Docks, Industries, and Houses.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Informal Meeting) (in Mining Institute, Newcastle-upon-Tyne), at 7.15.—E. L. Champness and others: Are we justified in using Steel and other Materials of Foreign Manufacture in the British Engineering Industries?

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7.30.—W. Cullen: Well Drill Blasting.

BRITISH ELECTRICAL DEVELOPMENT ASSOCIATION (at Royal Society of Arts), at 7.30.—R. C. Hawkins: Sales Aspects of Hotel Lighting.

JUNIOR INSTITUTION OF ENGINEERS (at Metallurgical Club, Sheffield), at 7.30.—P. S. Devereux: Chairman's Address.

INSTITUTE OF CHEMISTRY (London Section), at 8.—Dr. A. E. Dunstan: Gluckstein Memorial Lecture.

ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics and Comparative Medicine Sections), at 8.30.—Major A. A. Pryer, Dr. R. W. A. Salmond, Lieut.-Col. E. Middleton Perry, Dr. J. B. King, and others: Discussion on A Comparison of Radiological Problems in Man and Animal.

SOCIETY OF DYERS AND COLOURISTS (London Section).—Dr. Callan: Emulsifying Agents, Textile Assistants, and Finishing Materials: their Examination and Valuation.

MONDAY, DECEMBER 22.

INSTITUTION OF AUTOMOBILE ENGINEERS (Glasgow Centre) (at 39 Elmbank Crescent, Glasgow), at 7.30.—Dr. H. E. Merritt: Trends in the Transmission.

PUBLIC LECTURE.

FRIDAY, DECEMBER 19.

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Technical College, Cardiff), at 7.30.—J. Pryde: Human Engines.

CONFERENCE.

DECEMBER 19 AND 20.

SOCIETY FOR EXPERIMENTAL BIOLOGY (at Bedford College).

Friday, Dec. 19, 10 A.M. to 1.—Dr. M. C. Rayner: Observations on *Armillaria mellea* in Pure Culture with Certain Conifers.
J. G. Boswell: The Biochemistry of Dry Rot in Wood.
G. E. Blackman: The Effect of Nitrogen Compounds on the Botanical Composition of Grass.
Dr. W. H. Pearsall: Changes in the Constitution of *Beta* Leaves during Growth.
Dr. E. D. Adrian: The Activity of Isolated Nerves and Nerve Cells.
H. O. Bull: Conditioned Responses and Salmon Smolts.
2.15 to 4.—Dr. C. M. Yonge: The Relationship between Corals and Zooxanthellae.
Dr. T. A. Stephenson: The Growth of Corals.
E. Hindle: Thermophilous Organisms.
W. H. Thorpe: Experiments on the Biology of the Petroleum Fly *Psilopa petrolii*.
5.30 to 6.30.—E. Charles: Metabolic Changes associated with Pituitary Activity.
E. A. Spaul: Internal Secretions and Metamorphosis.

Saturday, Dec. 20, 10 A.M. to 1.—Symposium on the Permeability of Protoplasmic Membranes.
Prof. L. T. Hogben: Electrical Conductivity and the Permeability of Animal and Plant Tissues.
Prof. A. V. Hill: The Steady State across Biological Membranes.
A. D. Hobson: Changes in the Sea-Urchin Egg following Fertilisation.
R. J. Pumphrey: Electrical Potentials across the Membranes of the Trout Egg.
C. F. A. Pantin: Surface Permeability and the Evolution of the Blood Serum.

SATURDAY, DECEMBER 27, 1930.

CONTENTS.

Editorial and Publishing Offices:
MACMILLAN & CO., LTD.,
ST. MARTIN'S STREET, LONDON, W.C.2.

Editorial communications should be addressed to the Editor.
Advertisements and business letters to the Publishers.

Telephone Number: GERRARD 8830.
Telegraphic Address: PHUSIS, WESTRAND, LONDON.

Intellectual Co-operation.

THE inquiry into the work of the Committee on Intellectual Co-operation of the League of Nations, which has recently been carried out by a small committee under the chairmanship of M. Roland-Marcel, was promoted by the very success of the efforts of the Committee in this particular field of international co-operation. Problems were being submitted to the Committee in increasing numbers, and a real danger had already arisen when the committee was appointed in 1929, that efforts in the field of intellectual co-operation might either overlap unprofitably with the efforts of national organisation or be spread over so wide a field that, with the limited resources at the disposal of the Committee and of the International Institute of Intellectual Co-operation, effective attack on the individual problems would be impossible. No question of restricting the field of co-operation or the efforts of the various organisations already participating was raised. The existence of a very widespread realisation throughout the world of learning of the value and need for co-operation in thought, if the interests not only of peace but also of art and letters and science are to obtain adequate service in a world where politics and industry have already been internationalised, was evident and received further emphasis from the inquiry.

The committee's report covered the methods of work employed in this field, and certain recommendations were made regarding the constitution of the Committee on Intellectual Co-operation itself, together with a proposal to appoint an executive committee consisting of eight members to meet four times a year.

In addition, a programme of work was drafted on broad lines indicating the order of precedence to facilitate concentration upon a selected range of problems. Included in this programme are the development of the exchange of ideas and the promotion of personal contacts between intellectual workers of all countries; co-operation between institutions engaged on work of an international character; the general study of certain major problems of international bearing; international protection of intellectual rights; and in particular, the propagation by educational methods of the principle of the League of Nations, and a recommendation that the interrupted general inquiry into the position of intellectual life in different countries should be resumed.

Up to the present the conception of intellectual co-operation which has apparently dominated the

work of the Committee of Intellectual Co-operation and of the International Institute is one of co-ordinating the intellectual activities of the world, improving facilities for intellectual life where required, and generally promoting unity between the national groups of learning.

This conception, which was possibly the only one that a temporary committee with limited resources could have adopted, is, however, far from adequate to the problem as it is now revealed. Co-operation in the field of learning must follow the lines of co-operation in the field of industry, and effective collaboration must be established between men of science of different countries in the solution of certain problems. Such a conception would involve the Institute of Intellectual Co-operation becoming a kind of international academy where men of learning would assemble, and inevitably much larger resources than those at present available would be required.

It is, however, such a conception of intellectual co-operation which has inspired the most successful efforts in the field of international science, whether directed by the Committee on Intellectual Co-operation or not. The success of the health work of the League of Nations, as represented by the investigations of the malaria commission, the sleeping sickness commission in Africa, the Singapore Epidemiological Intelligence Bureau, etc., is the fruit of deliberate co-operation in a carefully selected field, the organised attack by scientific workers of different countries upon a common problem. Similar remarks apply to the work of the Committee itself in such fields as those of bibliography, library co-operation, the compilation of an annual list of notable books, and the inquiry into the durability of printed documents.

The revised constitutions recommended for the International Committee and Institute justify some hope that they will be more adequate to discharge the functions required by this conception of intellectual co-operation. There are, however, two points on which it is necessary to insist. The selection of the problems for international co-operation is a critical factor in determining the success of efforts in this field. Not only must the range of subjects be one commensurate to some extent with the resources available, but also it must be one which appeals sufficiently to the majority of the countries represented to ensure the loyal and energetic support of the national groups. Much of the work inevitably must be carried on through the national committees and other channels, and any lack of sympathy of understanding between these and the International Committee would undoubtedly be disastrous.

Equally important, however, is full freedom in selecting the problems for co-operation. Nothing would more surely jeopardise efforts in this field than limitations dictated by political considerations or prejudice. Real co-operation in the field of learning is only possible when the form and extent of that co-operation is determined by the free selection of appropriate problems by the workers themselves, influenced solely by considerations of the available resources and the advantages accruing to mankind.

It must be admitted that while direct political pressure is unlikely, it is difficult to detect or resist indirect pressure. For this reason the active prosecution by the Committee of inquiries concerning the international protection of intellectual rights is highly desirable, and there should be no diminution in the support given to the Advisory Committee on Professional Workers, set up by the International Labour Office in 1928, and on which the Committee on Intellectual Co-operation is represented.

For the full service of science or of any other branch of knowledge in the international sphere, the existence of representative professional organisations in the different countries, having an independent outlook and status, is of fundamental importance. Such organisations are more than a mere safeguard against the political control of efforts in the field of learning. Their contribution and participation are indispensable if the work of intellectual co-operation is to be continuously directed in practical channels and the dissipation of effort in academic or sterile directions is to be avoided.

Co-operation in thought is an essential condition of any form of international progress, and while efforts in the field of intellectual co-operation may well have a powerful indirect influence in promoting other forms of international co-operation, any divorce between learning and action in field of intellectual co-operation itself would be fatal to such an influence. For this reason a much closer association between the work of the International Committee and that of the national committees and of the national professional organisations is indispensable, if learning is to exert decisive influence in any field of international relations, and if the scientific study of international affairs is to be no mere academic formula but vital contribution of science in shaping the destiny of civilisation.

Mr. Winston Churchill on Miseducation.

My Early Life: a Roving Commission. By the Rt. Hon. Winston S. Churchill. Pp. 392 + 16 plates. (London: Thornton Butterworth, Ltd., 1930.) 21*s.* net.

NOT only out of the mouth of babes but also of public characters may come wisdom—even from a Winston Churchill. The autobiography he has recently published is full of meat for the would-be student of education. Obviously, being the son of his father, with the possibility of genes—this in recognition of the Bishop of Birmingham's reversion to bionomics—from other peculiar forbears, he could not be educable in any ordinary way. He has written a most fascinating account of his irresponsible upbringing, which should shame the devil in all but one of his schoolmasters. The book is to be studied by every teacher who desires to play an honest hand, a warning to every parent.

He went to a most fashionable and expensive preparatory school at seven. He had been so happy, he says, in his nursery with his wonderful toys: a real steam engine, a magic-lantern and a collection of soldiers already nearly a thousand strong. At school it was to be all lessons, seven or eight hours a day except half-holidays, football or cricket in addition. At once he was set down to master the First Declension Mensa, a table; mensa, O table, etc. He gives a most amusing account of his subsequent interrogation by the form master. He found the vocative a complete puzzle: why two meanings to the same word—why at one time 'a table', then 'O table'? Told that the latter was used in talking *to* a table, he ingenuously and naturally replied, that he never did. "If you are impertinent, you will be punished . . . let me tell you, very severely", was the conclusive reply. Flogging with the birch, in imitation of Eton, was the great feature in the school curriculum—the floggings "exceeded in severity anything that would be tolerated in any of the Reformatories under the Home Office". Being constitutionally unable to learn Latin, he had his plentiful share of whippings. So he hated school and lived a life of anxiety there during more than two years. The greatest pleasure he had was reading: when nine and a half, his father gave him "Treasure Island", which he devoured with delight. What a book this has been for youngsters—I well remember how it electrified my children, in fact, all of us, when it came out.

"My teachers saw me at once backward and precocious, reading books beyond my years and yet at the bottom of the Form. They were offended. They had large resources of compulsion at their disposal, but I was stubborn. Where my reason, imagination or interest were not engaged, I would not or I could not learn. In all the twelve years I was at school no one ever succeeded in making me write a Latin verse or learn any Greek except the alphabet. I do not at all excuse myself for this foolish neglect of opportunities procured at so much expense by my parents and brought so forcibly to my attention by my Preceptors. Perhaps if I had been introduced to the ancients through their history and customs, instead of through their grammar and syntax, I might have had a better record."

Here the interesting question may well be asked: Whether customs and history can, in any way, take the place of language study? Surely, it is mere pretence to say they can. The study of a language is something apart. Classical custom and history are profitably studied, I venture to think, only in a language with which the student is familiar. Warde Fowler is certainly the best of guides to Rome.

Churchill fell into a low state of health but was only removed from the school after he had a serious illness; he was sent to a small school at Brighton, kept by two ladies, in which he found an element of kindness and sympathy conspicuously lacking in his first school. Query: Should not preparatory schools all be in the hands of ladies? He remained there three years and gradually grew stronger. He was allowed to learn things which interested him—"French, History, lots of Poetry by heart, and above all Riding and Swimming".

He went to Harrow when he was twelve, entering "the inhospitable regions of examinations, through which for the next seven years I was destined to journey". The whole philosophy of examinations is to be read in the following passage in which he sets out this theme:

"These examinations were a great trial to me. The subjects which were dearest to the examiners were almost invariably those I fancied least. I would have liked to have been examined in history, poetry and writing essays. The examiners, on the other hand, were partial to Latin and mathematics. And their will prevailed. Moreover, the questions which they asked on both these subjects were almost invariably those to which I was unable to suggest a satisfactory answer. I should have liked to be asked to say what I knew. They always tried to ask what I did not know. When I would have willingly displayed my knowledge, they sought to expose my ignorance. This sort of treatment had only one result: I did not do well in examinations."

Yet as a man he has done well in after life, as do multitudes who, like him, fail at school. In my long

experience, it is never safe to write down a boy a fool: development so often waits upon age and opportunity. The account which Mr. Churchill gives of his performance at entrance to Harrow is most amusing: he was unable to answer a single question in the Latin paper. Yet the head master, Mr. Weldon, admitted him—doubtless upon his name. He was placed in the bottom form, of which he was last of all during nearly a year. Here comes a golden passage:

"... being so long in the lowest form I gained an immense advantage over the cleverer boys. They all went on to learn Latin and Greek and splendid things like that. But I was taught English. We were considered such dunces that we could learn only English. Mr. Somervell—a most delightful man, to whom my debt is great—was charged with the duty of teaching the stupidest boys the most disregarded thing—namely, to write mere English. He knew how to do it. He taught it as no one else has ever taught it. Not only did we learn English parsing thoroughly, but we also practised continually English analysis. Mr. Somervell had a system of his own. He took a fairly long sentence and broke it up into its components by means of black, red, blue and green inks. Subject, verb, object: Relative Clauses, Conditional Clauses, Conjunctive and Disjunctive Clauses! Each had its colour and its bracket. It was a kind of drill. . . . As I remained in the Third Form (β) three times as long as anyone else, I had three times as much of it. I learned it thoroughly. Thus I got into my bones the essential structure of the ordinary British sentence—which is a noble thing. And when in after years my schoolfellows who had won prizes and distinction for writing such beautiful Latin poetry and pithy Greek epigrams had to come down again to common English, to earn their living or make their way, I did not feel myself at any disadvantage. Naturally I am biassed in favour of boys learning English. I would make them all learn English: and then I would let the clever ones learn Latin as an honour, and Greek as a treat. But the only thing I would whip them for is not knowing English. I would whip them hard for that."

I would *force* this passage upon the attention of every English teacher and whip him hard until he mastered its meaning and acted in its spirit. In one of the schools with which I am connected, in which the curriculum had been entirely classical and mathematical, several years ago the decision was taken, partly owing to my insistence, to substitute English for Latin in the Lower School and then to enforce Latin only upon boys of distinct literary ability. The attempt was a failure because the classical masters would not and could not teach English: so they soon reverted to their early evil course of general Latin torture. The experiment has been an interesting one, confirming my suspicion that Latin needs but a lesser level of intelligence in the teacher, also explaining the failure of our schools under classical leadership. As a teacher, in my own subject, I have always insisted upon training in English composition being made part of the course—with little result, I fear as an example, judging from complaints such as that made recently by Sir William Pope. The time is at hand, however, when we must recognise our own language and those of other moderns.

Winston Churchill spent four and a half years at Harrow, three in the Army class. Officially, he never got out of the Lower School. He had a wonderful memory. While apparently stagnating in the lowest form, he gained a prize open to the whole school for reciting to the head master twelve hundred lines of Macaulay's "Lays of Ancient Rome" without making a single mistake. He passed the preliminary examination for the Army, while still almost at the bottom of the school. Here—let all mark this—his nursery toys came in. He was embarked on a military career. This orientation, he says, was entirely due to his collection of toy soldiers. He had ultimately nearly fifteen hundred. He tells how he arranged his forces, how his father one day made a general inspection and studied the scene with a keen eye and captivating smile. At the end, the father asked him if he would like to go into the Army. Thinking it would be splendid to command an Army, he said 'Yes' at once and was taken at his word. He afterwards learnt that his father had thought he was not clever enough for the Bar. However, the toy soldiers had turned the current of his life.

It took him three tries to pass into Sandhurst. He has much to say about Latin and mathematics and examinations, in this connexion, that should be of great interest to teachers generally. At the close of his career at the Royal Military College, he had been nearly twelve years at school:

"Thirty-six terms each of many weeks (interspersed with all-too-short holidays) during the whole of which I had enjoyed few gleams of success, in which I had hardly ever been asked to learn anything which seemed of the slightest use or interest, or allowed to play any game which was amusing. In retrospect these years form not only the least agreeable, but the only barren and unhappy period of my life. I was happy as a child with my toys in my nursery. I have been happier every year since I became a man. But this interlude of school makes a sombre grey patch upon the chart of my journey. It was an unending spell of worries that did not seem petty, and of toil

uncheered by fruition; a time of discomfort, restriction and purposeless monotony.

". . . I would far rather have been apprenticed as a bricklayer's mate, or run errands as a messenger boy, or helped my father to dress the front windows of a grocer's shop. It would have been real; it would have been natural; it would have taught me more; and I should have done it much better.* *Also I should have got to know my father*,† which would have been a joy to me.

"Certainly the prolonged education indispensable to the progress of Society is not natural to mankind."

Cannot we make school—'natural to mankind'? Surely, we must! Surely we could, if sympathy and scientific thought were brought to bear upon the task!

The desire for learning came upon Churchill when he was nearly twenty-two, a cavalry officer at Bangalore. It is a fascinating and suggestive story. He had picked up a wide vocabulary but caught himself using many words the meaning of which he could not define precisely. (We all do this but how many recognise their deficiency.) He had heard a friend say: "Christ's Gospel was the last word in Ethics". This sounded good but what were ethics. They had never been mentioned to him at Harrow or Sandhurst. There was no one at Bangalore to tell him about ethics for love or money. Other similar needs pressed upon him. Someone spoke of the Socratic method. What was that? Then there was history. He had always liked history but at school was given only the dullest, driest, pemmicanised forms like "The Student's Hume". How true is this and not of history alone! So he set himself to read history, philosophy, economics and things like that. The effect upon him is summarised in the following most noteworthy statement:

"When I am in the Socratic mood and planning *my* Republic, I make drastic changes in the education of the sons of well-to-do citizens. *When they are sixteen or seventeen*† they begin to learn a craft and to do healthy manual labour, with plenty of poetry, songs, dancing, drill and gymnastics in their spare time. They can thus let off their steam on something useful. It is only when they are really thirsty for knowledge, longing to hear about things, that I would let them go to the university. It would be a favour, a coveted privilege, only to be given to those who had either proved their worth in factory or field or whose qualities and zeal were pre-eminent. However, this would upset a lot of things; it would cause commotion and bring me perhaps in the end a hemlock draught."

May we not hope that it is not too late for him yet to qualify for that draught? Why not make himself Minister of Education in the next Government; then, following Christ's example, clear out the money-changers from the school temples.

The one strange thing is that nowhere in the book is the slightest reference made to the part played by 'natural science' and 'scientific method' in our affairs, beyond the vague statement:

"I wonder often whether any other generation has seen such astounding revolutions of data and values as those through which we have lived. Scarcely anything material or established which I was brought up to believe was permanent and vital, has lasted. Everything I was sure or taught to be sure was impossible, has happened."

Is the explanation, 'faulty schooling' or 'innate disability'—such as that shown towards learning Latin?

To me the book seems to be the most fascinating and important contribution to the study of educational practice of recent times, showing as it does the great need of an entire departure in method. On all grounds it is to be commended both to teachers and parents of sufficient intelligence to read between the lines and ponder the lessons it conveys; with sufficient courage to defy present soul-killing school conventions.

HENRY E. ARMSTRONG.

* It is noteworthy that nowhere does Churchill mention having had manual instruction.

(4) *Lecture Experiments in Optics.* By B. K. Johnson. Pp. 112. (London: Edward Arnold and Co., 1930.) 8*s*. 6*d*. net.

THE value of all branches of physics to industry is becoming more and more obvious every year, and manufacturers are finding that many important processes hitherto carried out empirically by their workmen, by methods depending

solely upon previous experience, can be controlled with far greater certainty by the use of physical apparatus. Among these controls there are many based more or less directly upon applications of optics, and the books under review contribute to the study of these applications.

(1) This is more particularly true of the first of the above books, upon the applications of interferometry, in which is given very concise explanations of a set of closely allied phenomena which have many important applications in metrology, in the study of spectra, and in the final surfacing and testing of lenses, lens-systems, and prisms. Interferometry has recently been brought into special prominence due to the famous experiments of Michelson and Morley, which have led to a revolution in our conception of the universe through the theories of relativity, largely suggested by and founded upon these experiments.

After a general introductory chapter, the author deals successively with interference phenomena under the following classification: (*a*) From a point or line source as in the Rayleigh interferometer and diffraction gratings; (*b*) involving a division of amplitude (Newton, Brewster, and Jamin); (*c*) by Michelson's method; (*d*) by simultaneous division of amplitude and wave front (Fizeau, Twyman and Green, Köster); (*e*) involving multiple beams (Fabry and Perot, Lummer).

This classification, while not free from criticism, will be of assistance in enabling the reader to distinguish between the different varieties of phenomena which can be produced—and no one can help being struck by the many types of interference which are possible and by its numerous applications. Each of the six chapters is followed by a valuable list of references to original papers on the subject of the chapter.

(2) We have in Dr. Martin's "Applied Optics" (of which this is announced as the first volume only) a general theoretical and practical treatment of the subject, which is based throughout on the ray or geometrical basis. In defending this mode of treatment, he rightly says that "the wave theory is no nearer 'reality' than the ray. It tells us nothing as to what actually happens in the region of the focus."

In the first two chapters are obtained the formulæ for lenses, single and in combination, and examples are given of trigonometrical ray-tracing. Chap. iii., on the "Physical Study of Light", deals briefly with diffraction, interference and its effects, radiation, and absorption. In the next chapter the aberrations of optical systems are dealt with—the sine condition, Seidel's aberrations, Petzval's condition, with their formulæ; but for the calculation of aberration-free systems the student is referred to Conrady's well-known "Applied Optics and Optical Design". In Chap. v. the author describes the eye and its properties, but he returns to physical optics—polarisation, crystallography, dispersion achromatism, and lens working—in the next two chapters; we should have thought that these chapters should have preceded Chap. v., for in the last chapter he deals with visual optics and the correction of defective eyesight.

All this is treated clearly and carefully and without the aid of higher mathematics; it should prove of very great assistance, not only to the ordinary students and those who desire to proceed to the higher branches of applied optics and optical design, but also to those who wish to understand thoroughly the refractive errors of the eye and their correction.

(3) The third book is essentially a practical one, giving empirical directions for the management of the microscope. It is probably not too much to say that the greater percentage of the users of the microscope do not know how to take full advantage of the wonderful instrument with which the manufacturers have provided them. The modern objective is perhaps one of the greatest products of inventive skill to be found in any field, and, when used as it should be, is a marvellously perfect instrument. Indeed, the workmanship of the lenses and their mounting are usually so good that the objective can generally be relied upon to give images which approximate closely to those theoretically possible; but only by close attention to every detail of manipulation is it possible to obtain such an image, and this, of course, is especially true of the high-power immersion objective.

It is in the management of the illuminating system that most users of the microscope fail. For some twenty or thirty years there was great controversy as to the correct method of illumination for high-power work, but it is now generally agreed that each point of the object should be illuminated by a cone of light focused as sharply as possible upon it. For this, a well-corrected sub-stage condenser must be employed to focus the source of light upon the object, and the aperture of this cone of light should be nearly as large as the aperture of the objective, if the objective is to be used to its full advantage. In Belling's book, the methods of centring and focusing the condenser, the mirror to be used, the type of lamp with its ground-glass screen and diaphragm, the aperture of the incident

cone of light, the use of colour screens, are all fully treated, with directions which no one should find difficulty in following.

In the first six chapters the several types of microscope are described, but there appears to be little guidance to the purchaser of the instrument as to the type which would best suit the work for which he is proposing to use it. Then follow the chapters on illumination, light filters, the condenser, the mounting of objects, the objective and other cognate subjects; in all, there are twenty-seven chapters. The more important chapters are summarised, and there is also added to several of them a list of rules. There is thus a good deal of repetition which some readers will think unnecessary, but it may be helpful in impressing the necessary steps upon the beginner. No attempt is made to give any theoretical discussion of the rules recommended; there appears, for example, to be no reference to the size of the diffraction disc, and no explanation why the limit of resolving power should depend upon the working aperture. Rules are all given empirically.

The book is written by a practical user of experience, and should be valuable to anyone who finds himself confronted with a complicated piece of apparatus, usually with very little reliable help. There is added a glossary, and a list of 157 references to books and papers on the use of the microscope.

(4) The fourth book is intended for the use of a lecturer or lecture-demonstrator in optics, and explains how the fundamental lecture experiments should be set up for class teaching. Projection experiments illustrating the laws of reflection and refraction and the passage of light through prisms and lenses are described in a thoroughly practical manner; in most cases diagrams are given, often also descriptions and photographs of the apparatus to be used. These experiments are followed by the more difficult projections of interference, diffraction, and polarisation phenomena. The ripple experiment and the projection of a flat soap or celluloid film would be much improved by the use of a large convex lens, say 4 in., 6 in., or even 8 in. diameter with a focal length of 20 in. to 30 in., placed over the ripple tank or film; the distances should be so arranged that this lens should either focus a slightly divergent beam from the lantern on the aperture of the projecting lens, or form an image of the arc itself upon the lens without the interposition of the ordinary lantern condenser. The beam should be reflected down through this large lens, on to the film placed horizontally; the light that is reflected back from the film passes a second time through the lens, and just before it reaches its focus it should be reflected forward by a prism into the projecting lens. When the projecting lens is being used for the projection of ripples, an iris diaphragm placed in or near it will help to intensify the image and show up the ripples.

Hydrogen Ion Concentration of Plant Cells.

Hydrogen-ion Concentration in Plant Cells and Tissues. By Prof. James Small. (Protoplasma-Monographien, Vol. 2.) Pp. xii+421. (Berlin: Gebrüder Borntraeger, 1929.) 30 gold marks.

THE difficulties in the way of determining the hydrogen ion [illegible]ntration of the interior of plant cells are great and they have retarded any real advance in our knowledge of the operation of hydrogen ion concentration as a factor governing the activities of the cell. Of the three more obvious methods, the most attractive, that of using micro-electrodes, has proved unsuitable even in the case of single cells, as apparently the results are liable to be affected very considerably by the oxidation-reduction potential of the protoplasm. A second method, that of measuring the hydrogen ion concentration of the expressed plant sap, has been much used, in spite of the known objections that it allows loss of carbon dioxide and also represents materials from cells of very different types, as well as from different parts of the same cell. The third method, that of examining the behaviour towards a suitable range of indicators of sections of plant tissue, has been largely used and developed by Prof. Small and his collaborators, and in this volume he summarises the results they have obtained, as well as the information available from other sources.

The data thus brought together are representative of a very wide range of plant types, and they include the reactions of the various tissues in the organs examined, as well as observations on the diurnal and seasonal variations. In regard to the latter, it is shown that the general tendency of plant tissues is to be more acid in winter. On the other hand, the external cells, which are generally more acid than the inner ones, tend to have a lower acidity in winter. Of equal interest is the author's discussion of the hydrogen ion concentrations of different parts of the same cell, and the observation that the cytoplasm and vacuole may have widely differing pH values. Thus in the

more acid cells of potato stems, for example, the cytoplasm was pH 5·9, the vacuole sap pH 4·8–5·2.

Of great value also is the discussion of the buffer systems responsible for the regulation of acidity in plant saps. The plants examined all differ in detail, but the present data show that the phosphates and bicarbonates, together with the salts of organic acids, exert with the free acids a predominant influence in regulating the pH of the sap. The systems present vary, of course, with the plant investigated. In sunflower, the rather feeble buffering effects are apparently due to phosphates chiefly. In apple juice, malates and malic acid appear to play a predominant part. The bicarbonate system so characteristic of animal tissues appears to be much less important in plants, which is not perhaps surprising in view of the great metabolic differences between plant and animal. The continuation of this work will be awaited with great interest by plant physiologists, who are, in the meantime, under a great debt to the author for marshalling the available masses of data into an intelligible and convenient form. W. H. P.

Our Bookshelf.

The Law of Aviation. By Dr. G. D. Nokes and Dr. H. P. Bridges. Pp. xix + 220. (London: Chapman and Hall, Ltd., 1930.) 12*s.* 6*d.* net.

THIS book is divided into two sections, dealing with conditions of peace and war respectively. Part I., "Peace"—which naturally deals with the laws, both national and international, governing civil aviation—is as satisfactory as any publication can be at present, remembering the state of flux in which aviation must inevitably be for many years yet. For example, the authors mention that the British Order in Council of 1923 "has been amended since that date not less than ten times".

The first part, dealing with British law, is clearly and fully set out, and constitutes an excellent standard text-book on the subject as it stood at the date of issue, but it should be read subject to alterations by the flood of subsequent amendments.

The chapters on international law are less definite. While the book sets out the laws, both ratified and otherwise, it necessarily cannot always give an account of interpretations of these that have not yet arisen. Unhappily, many nations to-day are using these laws obstructively, in a manner directly opposed to the obvious spirit of them.

The chapter dealing with regulations for safety in flight, both for airworthiness of aircraft and navigation rules, are in a happier condition. These regulations are now tending towards unification between the more important nations, and it is possible to discuss them with more confidence.

Part II. covers the regulation of military aeronautics in war and neutrality. It automatically divides itself into two broad divisions. The ordinary recognised rules of combat, modified as necessary to suit aircraft requirements, are obvious, and the authors' interpretation of them is quite definite. The type of warfare peculiar to aircraft—as, for example, bombing of towns, the exact rights of an airman escaping from a wreck by parachute, etc.—can only be covered by expressions of opinion. Even so, such opinions are valuable coming from legal experts, as both writers are. This section is provocative rather than informative, and it is of the utmost value if read from this point of view.

Lehrbuch der chemischen Physik. Zugleich dritte Auflage des "Grundrisses der physikalischen Chemie". Von Prof. Dr. Arnold Eucken. Pp. xvi + 1037. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1930.) 56 gold marks.

PROF. EUCKEN'S book "Grundriss der physikalischen Chemie" has now developed into a "Lehrbuch der chemischen Physik". The change of title follows naturally from the fact that the physical aspects of chemistry have developed so rapidly in recent years as almost to obliterate the boundary between the two subjects. Thus, on one side, thermodynamical theory has led to the replacement of concentrations by activities; on another side, quantum theory has made the specific heats of solids a matter for complex physical investigation; and, finally, the application of spectroscopy to the problems of atomic and molecular structure has made it necessary to include a treatise on optics in every work devoted to the study of physical chemistry. Whilst, therefore, space must still be found for the familiar concepts of mass action and the phase rule, there is an irresistible tendency for books on physical chemistry to become even more physical in character, until they become in fact books on chemical physics instead of physical chemistry.

Prof. Eucken's book covers more than 1000 pages and is therefore almost at the extreme limit of bulk for a text-book to be read *in extenso*, even by an advanced student in physical chemistry. Any further expansion would almost inevitably relegate it to the class of works of reference, from which particular chapters may be picked out for special study. Indeed, it already has distinct merits from the latter point of view, since the author has been able to give an account of band spectra, and of some other rapidly developing lines of research, which may be of real service to those chemical students who follow the progress of modern physics with difficulty and with much retardation. A translation into English would, however, very greatly enlarge the scope of its usefulness both in Great Britain and in the United States, since it is a serious handicap to be obliged to read in an unfamiliar language a book of such a size and on a subject which cannot be made easy, even in the hands of the most competent teacher.

Handbuch der biologischen Arbeitsmethoden. Herausgegeben von Prof. Dr. Emil Abderhalden. Lieferung 309. Abt. 9: *Methoden zur Erforschung der Leistungen des tierischen Organismus.* Teil 2, Hälfte 2, Heft 3: *Methoden der Süsswasserbiologie.* Pp. 1385-1549. (Berlin und Wien: Urban und Schwarzenberg, 1929.) 9 gold marks.

THE present part of this very useful work is concerned with methods of research in fresh-water biology and contains chapters on a variety of subjects by well-known workers. The portion by Dr. W. M. Rylov on the Limnoneusten is perhaps one of the most interesting as it deals with a subject only comparatively recently brought into prominence. The study of the biology of those organisms which have to do with the surface film is rapidly becoming more and more developed, thanks to Dr. E. Naumann, who suggested the term ' neuston ' for the life in this particular habitat. Very special methods are here required, for those of the ordinary plankton worker cannot be used.

The most important members of the limnoneuston are bacteria, monads, and *Euglena*, which live in masses and cause a variety of colours on the water surface. Larger forms may also occur, such as small Entomostraca and insect larvæ. This film life is often at its maximum in the early morning hours, lessening in the afternoon and sometimes broken up in the evening. A windless day is best for collecting. Even an oil-immersion lens is included in the list of desiderata for the excursions of the out-of-door research worker.

Other sections deal with the collecting and culture of Bryozoa, culturing of phyto-plankton and zooplankton, methods of manuring aquaria, ponds, and lakes, measurement of the penetration of light into the water by photoelectric cells, and methods of studying plant and animal communities. Dr. E. Naumann's chapters on the breeding of phytoplankton, Cladocera, Ostracoda, Copepoda, and pelagic Rotatoria are specially good and give a large amount of information in a small space.

The Truth about Publishing. By Stanley Unwin. Third edition. Pp. 359. (London: George Allen and Unwin, Ltd., 1930.) 7*s.* 6*d.* net.

THERE was a time when the craft of publishing was regarded as something as mysterious as the ' black art ', and perhaps scarcely less sinister. Even to-day the misunderstandings are scarcely cleared up: and the ' man in the street ' is still under the impression that the publisher is out to fleece the poor author while making enormous profits for himself. The only way to remove that impression is for the publisher to display his whole craft—frankly to lay all his cards upon the public's table: and this is what Mr. Stanley Unwin has done. In this book he describes with utter fidelity the reception and reading of manuscripts—with well-merited praise of the publisher's reader; the ' casting off ', and estimating of costs; the publisher's dealings with the author in all forms of agreement; the craft of book production; the business of selling and advertising; questions of copyright and ' rights ' generally; publicity, reviewers' copies, free copies, and literary agents.

All that Mr. Unwin says is true, and frankly and wisely he says it. The publisher has a difficult and responsible task. Apart from his technical and complicated business, he must have tact to deal with authors, a *flair* for what the public wants, judgment and sound literary taste—or at least the power of making right decisions from the ' reader's ' estimates—and, above all, a real desire to publish what is worth publishing. Mr. Unwin's book has already gone a long way towards developing a right understanding of the publisher's aims and work, and must be of the greatest help to the inexperienced author. The present writer, being himself an author-publisher, and thus able to see both sides of the publishing question, is glad of this opportunity of congratulating Mr. Stanley Unwin on writing so true and valuable an exposition.

Alluvium: Grundsätzliches und Programmatisches zur Geologie der jüngsten erdgeschichtlichen Epoche. Von Kurd von Bülow. Pp. viii + 178. (Berlin: Gebrüder Borntraeger, 1930.) 13·50 gold marks.

THE author uses the term ' alluvium ' in a stratigraphical sense, to include both the epoch that dates from the beginning of the last retreat of the ice and the various deposits which have been formed—and still are being formed—in different parts of the world during this unfinished epoch. Without going into great detail, a very clear and concise summary of our present knowledge of post-glacial deposits is presented. Geographical distribution, relations to climate, petrological characters, stratigraphical succession, and biological considerations all receive their due recognition. The descriptions of the deposits themselves are based on a cross-classification of climatic zones against facies. The latter include sub-aerial (æolian and soils); sub-aqueous (fluviatile and lacustrine); organic; glacial and fluvioglacial; marine and littoral; and volcanic. So far as practicable, each of these groups is described in turn for the polar, tropical, desert, and temperate zones.

The method is a valuable one, for not only is it well designed to cover the whole field, but it also brings out the many gaps that still remain to be filled up by further exploration and research. To afford an ideally sound basis for comparative stratigraphy and palæoclimatology, the changing characters of each facies as it is traced over the whole earth should be thoroughly known. This ideal is being actively pursued in the study of soils and peats, but even for these important facies it is still impossible to give a satisfactory world survey.

The book can be cordially recommended. It presents a well-balanced picture of a vast and ever-growing subject, and contains the very useful soil map of the world prepared by W. Hollstein for the "Handbuch der Bodenlehre." Not least of its merits from our point of view is the clarity of the style: the involved sentences beloved of many German authors are here notably rare.

Effect of Internal Stress on the Magnetic Susceptibility of Metals.

THE effect of cold-working or internal stress on the density, electric resistance, elastic constants, thermo-electricity, etc., for various metals and alloys has been a favourite subject of investigation, but few experiments have been made to ascertain the effect on the magnetic susceptibility of metals. We have been working at this subject for a considerable time and have found quite recently the extremely important fact that the diamagnetic susceptibility of a metal belonging to the cubic system decreases in a marked degree by cold-working, and that, by a severe cold-working, the susceptibility of copper is changed from diamagnetic to paramagnetic.

The cold-working was given to metals by means of a large press, the total maximum pressure of which amounted to 300 tons, or 300,000 kgm. All the necessary precautions for preventing the direct contact of the specimen with iron pieces, by washing it with acid, alcohol, etc., were taken. The measurement of susceptibility was made by means of Weiss's electromagnetic method (Honda's "Magnetic Properties of Matter" (1928), p. 125). Two of the most important cases are reported below.

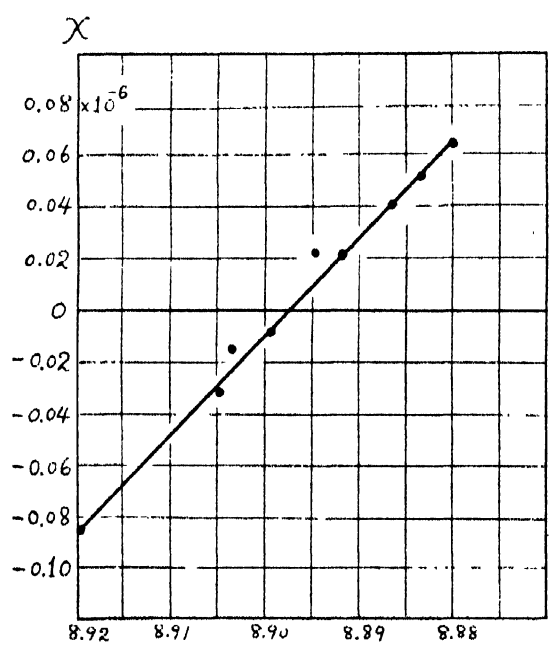

FIG. 1.—Copper.

(1) Copper: $\chi = -0\cdot083 \times 10^{-6}$, a weak diamagnetic metal. In general, the density of a metal diminishes with an increase of the degree of cold-working or that of internal stress. Hence we may take the change of density caused by cold-working as a measure of the internal stress. Fig. 1 shows a relation between the susceptibility and the density for different degrees of cold-working.

It is a remarkable fact that during the change of density from 8·921 to 8·887, the magnetic susceptibility of copper changes from diamagnetic to paramagnetic. The fact that this change is a true one was confirmed by an annealing experiment. It is well known that internal stress in copper is completely released by annealing it at 350°; hence the cold-worked copper specimen was vacuum-sealed in a small pyrex glass vessel and its susceptibility at different temperatures was measured during a very slow heating and cooling. The result is shown in Fig. 2. The paramagnetic susceptibility of the cold-worked copper rapidly decreases in the range 230°-330°, where the internal stress is released, and takes its original diamagnetic value $-0\cdot083 \times 10^{-6}$ at 350°. During cooling, the susceptibility remains almost constant down to room temperature.

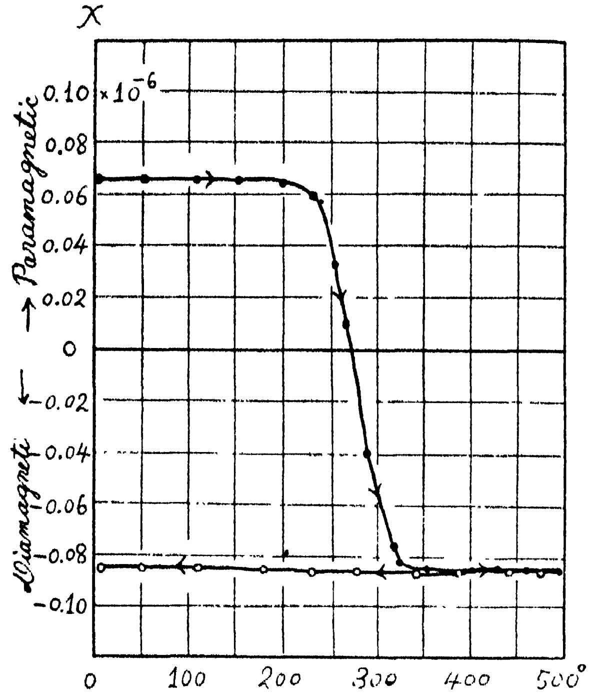

FIG. 2.—Cold-worked copper.

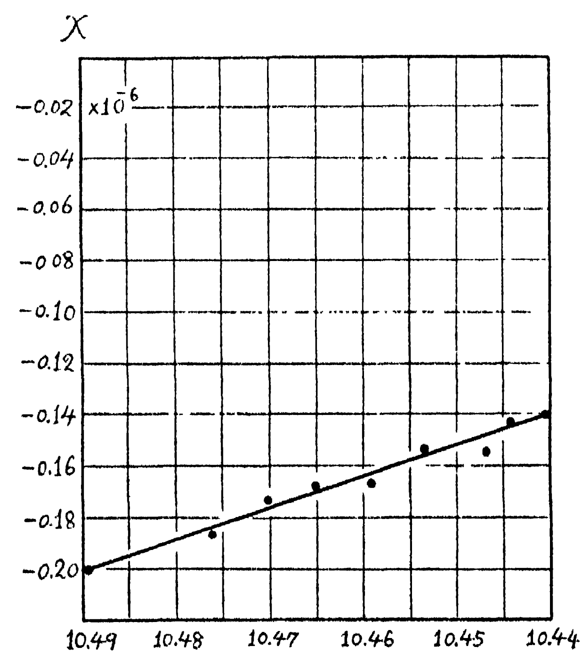

FIG. 3.—Silver.

(2) Silver: $\chi = -0\cdot200 \times 10^{-6}$, a diamagnetic metal. Figs. 3 and 4 show similar curves corresponding to Figs. 1 and 2 respectively. Thus, during the change of density from 10·489 to 10·439, the dia-

magnetic susceptibility changes from $-0{\cdot}200 \times 10^{-6}$ to $-0{\cdot}140 \times 10^{-6}$. From the course of the curve, it might be expected that at an extremely high stress (density $= 10{\cdot}365$) the susceptibility of cold-worked

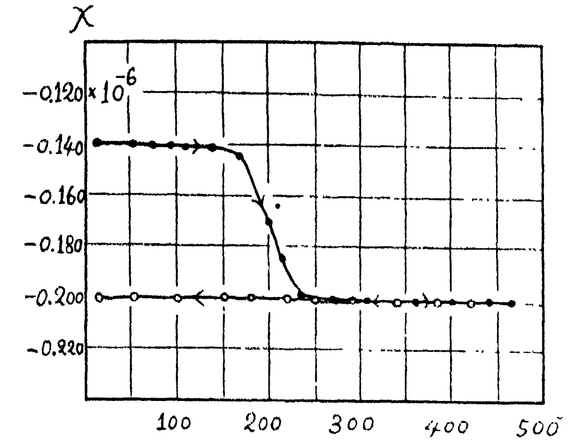

FIG. 4. -Cold-worked silver.

silver wi change from the diamagnetic to a paramagnetic. The annealing experiment (Fig. 4) shows also that the change is a true one.

Thus we have now two examples, in which the magnetic susceptibility of a substance changes its sign with external conditions, namely, tin and copper; the former (*l.c.*, p. 134) changes its sign with temperature and the latter with internal stress.

According to Honda's theory of magnetism (*l.c.*, p. 185), the magnetic susceptibility of a substance is the sum of a paramagnetic term χ_p and a diamagnetic one χ_d, that is,

$$\chi = \chi_p - \chi_d.$$

By applying a stress to a metal its density diminishes, and this will cause an increase of χ_p by the decrease of mutual action among neighbouring atoms (*l.c.*, p. 181), and also an increase of χ_d by an increase of bound electrons (*l.c.*, p. 186) at the cost of free electrons, so that in the case of diamagnetic metals the difference $-(\chi_d - \chi_p)$ may numerically decrease as in the case of silver, and may even become positive as in the case of copper, provided that the rate of increase of χ_p is greater than that of χ_d.

Effect of a Direct Current on the Frequency of a Sonometer Wire.

IN a communication in NATURE of May 31, p. 819, Messrs. D. V. Gogate and Y. G. Naik describe an experiment showing that a vibrating sonometer wire undergoes a lowering in frequency when placed in a D.C. circuit. They affirmed that this unexpected result was due neither to the heating of the wire nor to a magnetic action, but at the time offered no explanation of the cause. In their experiment a sonometer wire was tuned to the frequency of an electrically driven fork so that synchronous vibrations of a large amplitude were set up in the wire. When a direct current was sent through it, the amplitude was immediately reduced, and could be restored again to its original width by shortening a little the distance between the bridges, thus showing that the frequency of the wire had been lowered.

This seemingly inexplicable phenomenon aroused some interest in this laboratory, and at the suggestion of Dr. S. J. M. Allen a detailed investigation was carried out. It was found that there is nothing mysterious about the effect. It is simply the result of a decrease of tension in the vibrating portion of the wire due to thermal expansion and the friction at the bridge. This explanation can be verified by the following experiments:

(1) The experiment of Messrs. Gogate and Naik was repeated and similar results were observed.

(2) To test the effect of heating on the wire, a still wire was strung parallel and close to it. When a current was sent through this still wire, a decrease in amplitude of the vibrating wire, similar to that of the previous experiment, was observed. However, when a sheet of mica was interposed between the two so as to cut off immediate heat transfer, the passage of a current through the still wire produced no change in amplitude. The effect of heating was further tested by holding a hot rod close to the vibrating wire. A change in amplitude and accompanying change in frequency, similar to that produced by the current, was at once observed, thus showing that the change in frequency was due to heating.

(3) The fixed end of the wire was attached to a small spring balance which was firmly clamped to the first bridge. Tension was maintained by a weight and pulley. When a current was sent through the vibrating wire, a displacement of the pointer on the balance, as viewed through a low-powered microscope, indicated a decrease in the tension of the vibrating portion. When the current was broken, the pointer moved back to its original position. This proves that the frequency is lowered by a decrease in tension. A curve plotted with change in tension as ordinates and current as abscissæ takes the form of a parabola, but if the square of the current is used as abscissæ the result is a straight line, showing that the change is directly proportional to the heating of the wire.

Wires of different materials were used. It was found that for those having large expansion coefficients the tension change was greater than the corresponding change for wires having small expansion coefficients; for example, the tension change for German silver, having a coefficient of 0·000018, was almost twice as great as that for steel with a coefficient of 0·000010. This shows that the change in tension is dependent upon the expansion of the wire.

As the wire expands and moves over the bridge its motion is opposed by the friction of the bridge so that the slack in the wire is not all taken up by the weight. The tension in the vibrating portion, then, will differ from that on the opposite side of the bridge by an amount equal to the frictional force at the bridge.

(4) To test the effect of the bridge friction, the sonometer was placed in a vertical position and the bridge replaced by a pulley, thus reducing the friction to a minimum. Then, when a current was passed through the vibrating wire, no change in amplitude, and consequently no change in frequency, could be detected, even though large currents were passed through the wire.

Quantitative results will be published elsewhere.

A Biological Station for the Red Sea.

THE Red Sea is one of the most interesting in the world, and the usefulness of a biological station on its shore scarcely needs emphasis. Owing to its peculiar physical features—desert coasts and a shallow sill separating it from the Indian Ocean—warm water, with active coral growth, and, with

that, the Indo-Pacific fauna, extends much farther north than in any other sea, vigorously growing reefs occurring even at the entrance to the Gulf of Suez in latitude 28° N. Living corals and Alcyonaria of tropical genera are to be found even at Suez, while at a point a few miles south is a bed of at least sixteen species of coral with four of Alcyonaria; coral may, however, grow without any reef formation, and it is doubtful whether a growing reef exists within the Gulf of Suez.

Though much has been done on coral variation, ecology, and physiology, much more remains, and the whole tropical fauna offers problems which have only been touched as yet. A laboratory accessible from

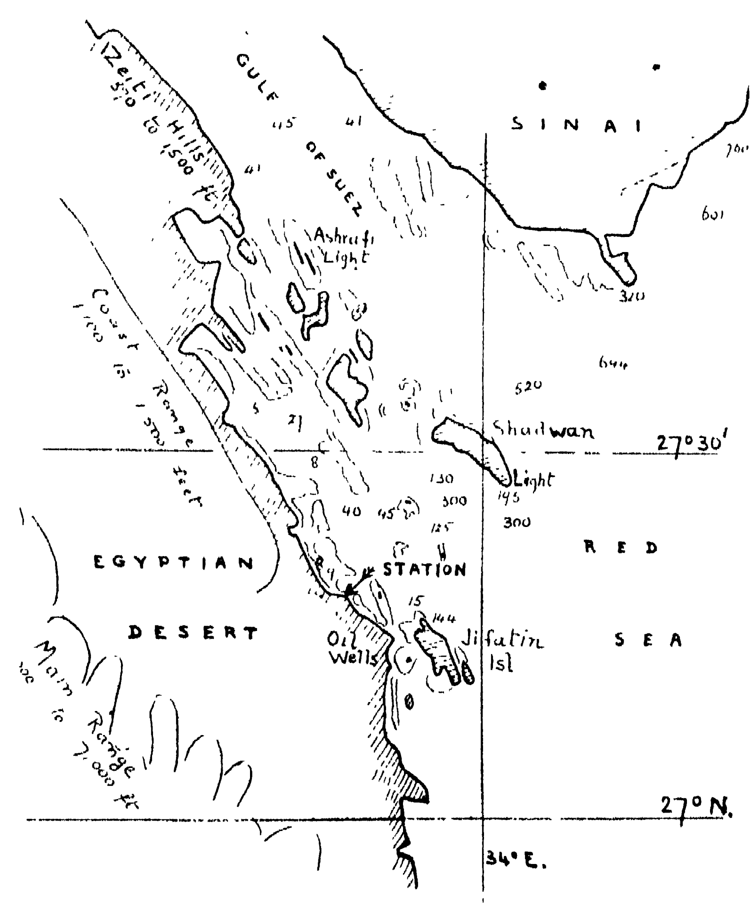

FIG. 1.

the universities of the Old World, and on this classic ground, the origin of so many types, has long been wanted. It will therefore be of interest to all biologists to hear that the new Faculty of Science in the University of Egypt has not been slow to realise the advantage in which it is placed with regard to tropical marine biology, and had carried out two expeditions to the Red Sea before I myself became actively interested.

The site finally selected is near the Ghardáqa Oil Fields (the name is given as "Hurghada" on the charts, an inversion of the Arabic), within the shelter of the Jifatin and other islands, in lat. 27° 13′ N. A glance at the chart (Red Sea, Strait of Jubal), reproduced as Fig. 1, shows that we are near the southern end of the remarkable maze of reefs and islands, occupying the north-west corner of the Red Sea just south of the entrance to the Gulf of Suez, which is a continuation of the Zeiti coast range and ends in the high island of Shadwan. We thus have every form of reef at our doors, a great area of sheltered water of varying depths, with the 100 fm. line only a few miles to seaward. Our buildings will be on a raised coral reef, the flat surface of which is disintegrated into a gravelly sand; below is a little beach, and reef flats with weeds and marine phanerogams, with scattered corals and Alcyonaria along its edge. A short distance to sea is as beautiful a coral bed as I have seen anywhere, rising to the surface to form a reef flat of the simplest construction. The outer reefs are of greater age and more complex construction, with a different fauna of corals; while of the Alcyonaria, for example, *Tubipora* grows in large masses, the red skeleton completely hidden under the long, grey, or grey-green polyps. As in most tropical seas, the Alcyonaria are both abundant and varied; *Xenia* along shore, the large fleshy forms on the outer reefs, the lovely scarlet or yellow *Spongodes* and the rarer hard-stemmed gorgonians, in deeper water, and other groups, like these, rare and inconspicuous in European seas, are to be seen here in all their beauty merely by looking over the side of a boat.

There is therefore little or no need for a show aquarium at Ghardáqa: Nature provides more than could be shown in any tanks, however well stocked and skilfully kept; and, as the station is for the use of students and research workers only, this expensive department is to be dispensed with. In addition to the vessels used for research inside the laboratories, it is proposed to build two or three shallow ponds on the reef flat, in which the water will be circulated by pumps, and in these close observation of experimental animals will conveniently be carried out, or material can be kept alive until needed indoors. There is plenty of sheltered, yet clean, water in which cages, etc., can be safely anchored.

The station should be useful to other than marine biologists, forming a centre from which the desert fauna and flora, both of the plain and mountains, may be studied more thoroughly than is possible from a temporary camp and when restricted to the cooler months. To the geologist the region is of exceptional interest, not for its oil yield alone, and combined biological and geological exploration of the adjacent islands and reefs may throw light on the coral reef problems. For the inland excursions the necessary motor transport will be provided.

The climate of the Red Sea has an evil reputation, quite undeserved so far as Ghardáqa is concerned, since it is well north of that area of low barometer which separates the prevalent north-west and south-east winds of the ends of the sea, and in which those "cities of dreadful night", Port Sudan, Suakin, and Massawa, have the misfortune to be placed. This is a point of importance to university research workers, who are often free only in the summer months, and it is hoped that, in the selection of the site and design of the buildings, my long experience of the hot central section of the Red Sea will enable me to ensure comfort at all seasons. Data provided by the meteorological office of the Egyptian Government show that at Ghardáqa the average maxima are higher by 1·5° C. than in Cairo during the winter, an advantage to Ghardáqa; in May the same, namely, 32° C.; in June and July slightly lower, and half a degree

higher in August, September, and October. The highest averages are in August, the maximum then being 35·6° C., the minimum 25° C. (77° F.). In point of personal experience, Ghardáqa is far more comfortable than Cairo in August, since every building is open to the breeze, and the wearing of coats, collars, and ties is not enforced.

The station is readily accessible, by land from Cairo, by sea from Suez. The former route involves a night in the train and an eight-hour journey by car across the desert and the Red Sea mountains, following the old road by which the Romans carried porphyry from their quarries in the mountains. From Suez the Anglo-Egyptian Oil Co.'s steamers sail three times a week, reaching Ghardáqa in 16 hours, and supply the oil camp with abundance of fresh water and provisions, so that the hardships of desert life are conspicuous by their absence.

It is hoped that the station will be complete in about a year's time, not only as regards laboratories, apparatus, machinery, and launch, but also with rest houses for research workers and students.

Cairo.

Change of the Dielectric Constant of Nitrobenzene with Temperature.

I HAVE made a study of the dielectric constant of nitrobenzene as a function of temperature, using a method depending on the beats of two high frequency oscillation circuits, as described by M. Wolfke and W. H. Keesom.[1] Some details concerning the apparatus have been published already in a short note on the dielectric constant of ethyl ether.[2]

It should be stated that the temperature was determined with an error not exceeding 0·005°, and

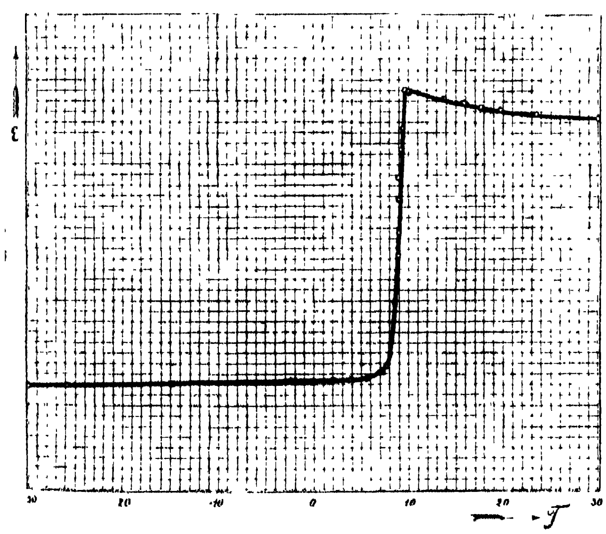

FIG. 1.

the changes in the fifth decimal of the value of the dielectric constant were still discernible.

The changes of the dielectric constant of nitrobenzene with temperature have been studied by Abegg and Seitz.[3] These authors, however, used under-cooled liquid which was not purified sufficiently to obtain results with a very high degree of accuracy, as they themselves point out in their paper.

In my experiments the nitrobenzene was obtained from benzene crystals and was carefully purified by means of the most recent methods. It was afterwards fractionised five times at the interval of 0·05° C.

The dielectric constant was studied through the temperature interval −75°, +30°; special care being taken in the neighbourhood of the liquefaction point. The measurements were made both at increasing and decreasing temperatures.

With decrease of temperature the dielectric constant of nitrobenzene steadily increases from the value 35·4 at 30·01° up to the maximum value 35·18 at 9·6°, in the immediate neighbourhood of the solidifying point. A sharp decrease is then observed down to the value 11·82 at 7·713°, and then a slow asymptotic decrease down to the limiting value 9·709 at −75° C.

These observed changes of dielectric constant of nitrobenzene with temperature do not agree with the results of Abegg and Seitz.

Some irregularities in the rate of change of the dielectric constant in the region of sharp decrease (that is, between 9·6° C. and 7·713° C.) suggest the possibility of some complications in the neighbourhood of the solidifying point of nitrobenzene. A further study will be made to clear up this question.

The change of the dielectric constant of nitrobenzene at temperatures described above is represented on the accompanying graph (Fig. 1).

A full report of the investigations concerning ethyl ether and nitrobenzene will appear in the *Comptes rendus des Sciences de la Soc. Polon. de Physique*, Warsaw, and the *Physikalische Zeitschrift*.

Persian Science and Jundishapur.

MAY I take the opportunity, afforded by the review in NATURE of Dec. 6 of Sir Percy Sykes's "History of Persia", of directing attention to a point of interest to students of the history of science?

Readers of NATURE will be aware that what we call 'Arabic' science was to a very large extent the work of Persians who wrote in Arabic, though deriving from Greek, Syrian, and Hindu origins. It is also generally known that one of the greatest centres of Persian science was the school or university of Jundishapur. But there appears to be no general agreement as to where this school was situated; and I am hopeful that readers of NATURE may be able to throw some light on the matter. I give below some of the divergent views of authorities I have consulted. It will be noted that the name is spelt in a number of different ways, and, but for encroaching unduly on the space available I would accompany this letter with a plea that a little science should be applied to the transliteration of Oriental names.

Gibbon in his "Decline and Fall of the Roman Empire", chap. xlii., places Gondi Sapor near Susa. Browne in "History of Persian Literature", vol. 1, p. 305, quotes from Carl Brockelmann to the effect that Jundi-Shapur was in Khuzistan, which does not conflict with Gibbon's statement. Sykes in his "History of Persia" (I have not yet seen the latest edition), vol. 1, p. 437, states that Gundisapur is the city of Shapur near Kazerun. This does not agree with the statement that it was in Khuzistan, which also has the support of the "Encyclopædia of Islam" under the heading 'Djundai-Sabur'. The "Encyclopædia Britannica", 10th ed., art. "Arabian Philosophy", refers to "Gandisapora or Nisabur in the east of Persia", thus giving the city a third location. In the 11th edition it is spelt "Junday Shapur" in the article on "Disful", and "Gundev-Shapur" in the article on "Shapur". Both articles place it near Susa. But in

the 14th edition the index says: "Gandisapora, see Nishapur". I find no mention of Gandisapora in any of the articles in this edition referring to Nishapur, so must assume that they are supposed to be the same place. But Nishapur is in Khorasan, whereas the other sites are in Khuzistan and Fars respectively. Berthelot, "Histoire des Sciences", vol. 2, introduction, refers to Gandisapora but does not say where it was. Other references bearing on this matter will be found in Sarton's "Introduction to the History of Science", p. 435, and in "Lands of the Eastern Caliphate", by Le Strange, pp. 262-3; but they do not enable me to decide definitely where this city, so important in the history of science, actually was.

It may be that differences of opinion have arisen through the name of the Persian king Shapur I. (also spelt Sapur, Sapor, Sapores, etc.) being closely associated with Nishapur (Nisabur, Naysabur, Niv-Shapur, etc.) in Khorasan (Khurasan, Korasan, etc.); also with Shapur (Bishapur, Nishapur, Bih-Shapur, Wih-Shapur, Bana Shapur, Shahristan, etc.) in Fars; also with a third city the ruins of which are still to be seen on the road between Shuster and Disful.

Sir Percy Sykes informs me that the city in Fars, near Kazerun, which he believes to have been Jundishapur, was very important with Sasanian bas-reliefs and is still termed 'the city of Shapur'.

Determination of the Velocities of Projectiles by Light Interception.

WE have developed a light interception method for the determination of the velocity of projectiles in the immediate neighbourhood of the muzzle.

The principle of the method is shown in Fig. 1.

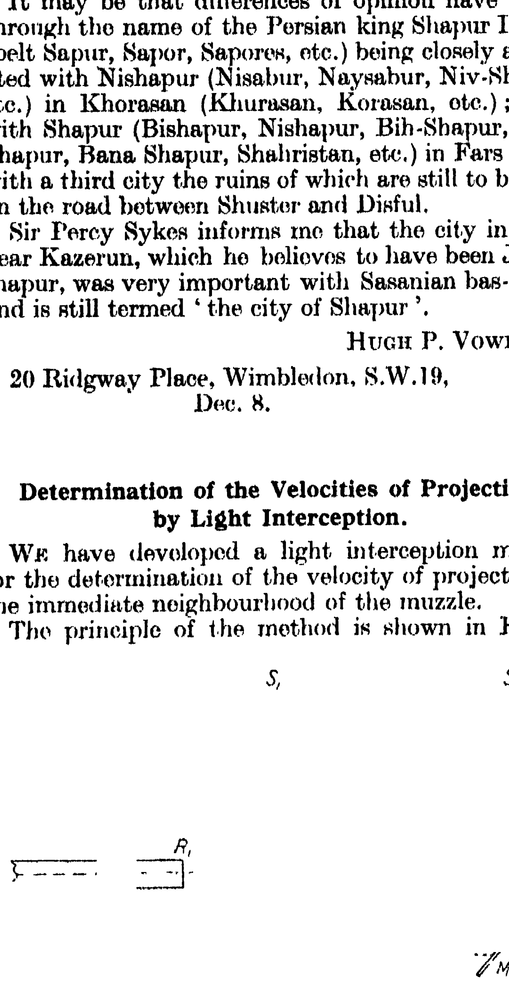

FIG. 1.

RR_1 is the gun. Two beams of light S_1I_1 and S_2I_2 cross the line of flight of the projectile and are brought to a fine focus upon it. The beams are turned by mirrors M_1M_2 and gathered to linear foci, colinear in a vertical sense, on the film of a high-speed camera. The projectile in its flight intercepts first the beam S_1I_1 at I_1 and then the beam S_2I_2 at I_2, causing breaks in the bands of light photographed on the film of the high-speed camera. Time marks are impressed upon the film by means of an Eccles' valve-maintained tuning-fork of 1000~ which carries a small concave mirror on one prong and deflects a beam of light falling upon it. Knowing the distance I_1I_2 and the time between interceptions on the film, the velocity of the projectile may be readily determined. One beam alone may also be used for velocity determinations if the length of the projectile is known.

The method has been used successfully for the determination of the velocity of rifle bullets and shot-gun ejecta. Fig. 2 is a photograph of a rifle bullet velocity determination with two interceptions. In

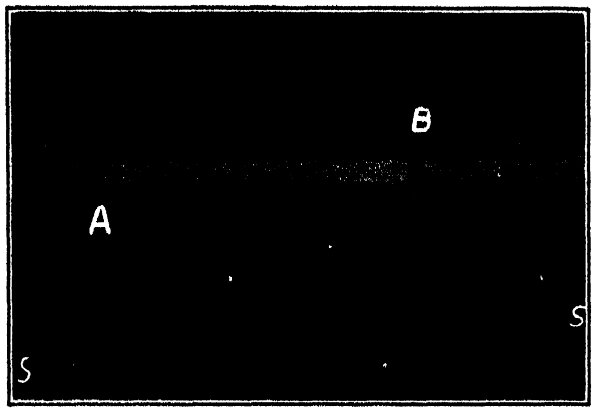

FIG. 2.—A and B indicate the first and second interception of the line of flight by light rays. SS is the time marking.

the discharge from a shot-gun, the interceptions are complex, showing shot column, wad, and cards.

A complete description of the method is being published at an early date.

Viscosity of Electrolytes.

AN important conclusion arrived at in two recent papers on the viscosity of electrolyte solutions [1] is that the relative viscosity of all electrolytes must be greater than unity at high dilutions. It follows from this that the phenomenon of 'negative viscosity', which is well known to occur in solutions of salts of potassium, rubidium, etc., must disappear at the highest dilutions, and that the presence of these salts in very small concentration must increase the viscosity of water.

Heretofore there has been no authenticated instance of this phenomenon. We have therefore measured

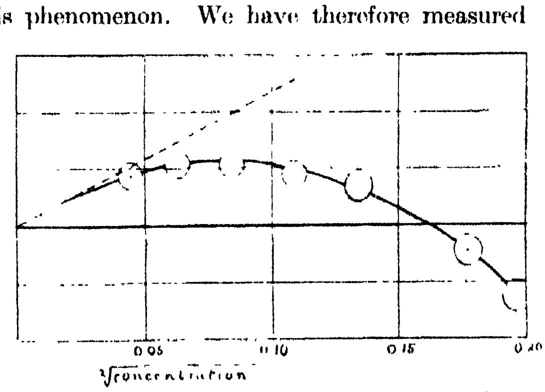

FIG. 1.

the viscosity of dilute aqueous solutions of potassium chloride at 18° C. in silica and glass viscometers of the Washburn-Williams type. Our results for the glass viscometers are represented in the accompanying diagram (Fig. 1), in which relative viscosity is plotted against the square root of the concentration of the solution.

These observations seem unequivocally to show viscosities greater than that of pure water up to a concentration of 0·025 N. The dotted line represents the limiting slope predicted by the Dole-Falkenhagen

equation; it will be seen that this line is tangential[1] to the extrapolated curve drawn through the experimental points. A good straight line is obtained by plotting $(\phi - 1)/\sqrt{c}$ against $\sqrt{c}$ (*vide* Jones and Dole) and its intercept on the axis of zero concentration is -0.0052, in satisfactory agreement with the value of -0.0046 predicted by the Dole-Falkenhagen equation. The values obtained in the silica viscometers are less concordant but indicate clearly the existence of relative viscosities greater than unity over the same concentration range as that indicated above. It is possible that measurements made with a capillary viscometer at these high dilutions are materially affected by some sort of electro-kinetic effect which will vary with concentration; it is possible, for example, that specific ion adsorption in the capillary may produce an electrical 'drag' on the flowing liquid. It is for this reason that we are carrying out measurements in both silica and glass viscometers.

Raman Spectra of Some Triatomic Molecules.

IT was observed by me [1] and also independently by Dickinson and West [2] that liquid sulphur dioxide gives three Raman frequencies. The measured wave-number shifts were 526, 1146, and 1340, the line corresponding to 1146 being much more intense and sharper than the two others. The spectrum of sulphur dioxide gas has since been successfully photographed by me and exhibits a frequency 1154, which is distinctly greater than the value 1146 obtained with the liquid and agrees much better with the infra-red value 1152 found for the gas by Bailey, Cassie, and Angus.[3] The two other lines are presumably too weak to be recorded in the case of the gas.

The spectrum of liquid hydrogen cyanide has also been photographed by me and shows a triplet giving the frequency shifts 2076, 2097·2, and 2122, of which the middle component is much more intense than the others: its value 2097·2 is probably accurate to within $\pm$ 0·2. Dadieu and Kohlrausch give it as 2092 and do not record its companions.[4] It is interesting to note that Barker,[5] working with hydrogen cyanide gas, found the corresponding infra-red absorption band at $4 \cdot 7\mu$ to be a triplet, the maxima appearing on his curves at 2088, 2103, 2117 wave-numbers, in each case only a few units different from the values reported above for the liquid.

The case of carbon disulphide has been the subject of investigation by several authors. Krishnamurti found recently [6] that the intense line at 655 has a feeble companion at 647, and that the line at 800 is also diffuse. His results have been confirmed by me, and in addition three new very feeble bands at 4438, 4605, and 4680 A. have been discovered in the spectrum of carbon disulphide excited by the mercury line 4358·3 A. when photographed with long exposures. If these are assumed to be due to Raman transitions, they give us three new characteristic frequencies of carbon disulphide, namely, 412, 1229, and 1577.

Dangerous Properties of Ethylene Chlorhydrin.

IN the issue of NATURE for Sept. 8, 1928, p. 376, appeared a note on a paper by Mr. F. E. Denny read at the annual meeting of the Society of Chemical Industry in New York, in which he advocates the use of ethylene chlorhydrin for speeding up the sprouting of potatoes, and in which it was indicated that the use of this substance is quite safe from the point of view of the workmen applying it.

During the course of its work in connexion with safety in chemical factories, the Association of British Chemical Manufacturers has recently had brought to its notice (*Zentr. Gewerbehygiene*, 1927, **4** (9), 712) information indicating that this substance possesses unsuspected toxic properties, and that several deaths have occurred in Germany from inhaling the vapour. A somewhat similar case with a fatal termination is reported, for the first time in Great Britain, in the annual report of the Chief Inspector of Factories and Workshops, 1930, p. 95.

The substance apparently acts as a metabolic poison with a specially severe effect on the nervous system, producing muscular weakness, inertness, refusal of food, sleepiness, and finally death by paralysis of respiration.

In view of the increasing use of this substance as a solvent for resins, wax, cellulose, and in the lacquer, paint, and pharmaceutical industries under conditions encouraging evaporation, it seems advisable to direct attention to the above observations, particularly as the substance itself is apparently innocent of all dangerous properties and its action is for that reason all the more subtle.

Determinism.

THE implications of Heisenberg's principle of uncertainty are often seriously confused owing to the ambiguity of the expression 'to determine'. In the present connexion this should mean 'to cause'; what further meaning should be assigned to 'cause' itself is here immaterial. Among other physicists, Prof. G. P. Thomson asserts in "The Atom" (p. 190) that "physics is moving away from the rigid determinism of the older materialism into something vaguely approaching a conception of free will". In any such statement 'determinism' appears to have the sole meaning of 'unvarying causation', apart from which 'free will' is totally irrelevant. Most unfortunately, however, 'to determine' often means merely 'to ascertain', as when we say we cannot 'determine' the exact state of the case. On pp. 193, 194, then, Prof. Thomson substitutes this alternative meaning: "velocity is quite uncertain. A similar result applies if we try to determine the velocity of the electron. . . . There is an exact reciprocity between the exactness with which position and momentum can be determined." Here 'to determine' plainly means not 'to cause', but simply 'to ascertain'. But every argument that, since some change cannot be 'determined' in the sense of 'ascertained', it is therefore not 'determined' in the absolutely different sense of 'caused', is a fallacy of equivocation.

A New Theory of the Evolution of the Insects.

By Dr. R. J. TILLYARD, F.R.S.

A CRITICAL study of the various theories extant concerning the origin and evolution of the insects as a class reveals that there is so far no general agreement amongst biologists on the point at issue. Handlirsch derives them direct from Trilobites. A long line of authors champion the theory of derivation from Crustacea; well-known exponents of this theory are Hansen, G. H. Carpenter, and Crampton. Versluys would derive them, with all other Arthropoda, from the Onychophora, by way of the Myriopoda, considering both Trilobites and Crustacea as side-branches which took to the sea. The famous Campodea Theory of Brauer is only one of a number of more or less diverging views which would derive the insects more or less directly from some type of Myriopoda.

It is interesting to notice which type is considered the most primitive of all insects, according to these various theories. For Handlirsch, the original insect was a winged Palæodictyopteron which arose somewhere in the Carboniferous; the Thysanura and other supposedly primitive apterous forms are, for him, debased side-branches of an originally winged main stem. For those who would derive insects from Crustacea, the family Machilidæ of the Thysanura is the most primitive type. Those who support the myriopod theory find the closest connexion between the Symphyla on one side and the Campodeidæ on the other.

All the theories so far put forward appear to fail at some critical point. Few entomologists can believe that winged insects preceded the oldest wingless forms; it is on this point that Handlirsch's theory, so clearly and fascinatingly presented by its talented author, fails to make appeal. The argument on segmentation drives the adherents of an origin from Crustacea to support a fairly highly evolved type of crustacean, somewhere near the lower Malacostraca, as the ancestor of Machilidæ; but such a theory breaks down when put to the test of detailed analysis. The old crux of the position of the genital pore still stands unsurmounted by those who would like to derive the Campodeidæ from the Symphyla. There is, in fact, no generally acceptable theory as yet.

Where nobody has succeeded, it would seem indeed rash for anyone to make a further attempt. I have, however, done so, not so much with the hope of convincing everybody that I have found the solution, as with the desire to stimulate new lines of thought on a very old problem.*

The theory is built up from the results of an analysis of the evolution of (*a*) segmentation, (*b*) the walking leg, and (*c*) the reproductive system, in insects and other arthropods. As the results obtained from all three analyses were found to agree quite closely, the general theory so constructed was then applied to the evolution of other organs, including the various internal systems, and also to the embryology, with the result that it appears to stand the tests quite well. It also does no violence to the geological record.

In segmentation, attention may be directed to the existence of a nauplius larva in the more primitive types of Crustacea, and to the 'telescoping' of this larval type into the embryology, in certain specialised types such as crayfishes and syncarids. The conclusion is drawn that the Crustacea are derived from a *nauplioid ancestor*, though not from any actual type of nauplius. This would imply *an original lesser amount of segmentation* both in the head and in the body of the animal. As regards the head, the suggestion arises, by comparison of the nauplius head with that of *Peripatus*, that it was originally only four-segmented, and that the mouth was originally closed behind by a flap or process which was not formed from segmental appendages, but was merely a process of the mandibular segment. From this arose the paragnaths in Crustacea and the hypopharynx and maxillulæ or superlinguæ of insects. The addition of either one or two maxillary segments to the head gave rise to all the five- or six-segmented heads now found in Myriopoda, Insecta, Crustacea, etc.

Turning next to segmentation in the Myriopoda, we meet the phenomenon of *anamorphosis*, or the addition of segments during ontogeny by interpolation in front of the anal or preanal segment. Such addition may take place either singly or in groups. The young larva hatches out with relatively few body segments, and at each instar there is an increase by anamorphosis, until the full number is reached. An analysis of the ontogeny of the primitive myriopod group Pauropoda shows that the young hatch out with only six postcephalic segments, of which only the second, third, and fourth carry legs. This is the 'six-legged larva'. It is followed by a ten-legged larval stage, a twelve-legged stage, and a sixteen-legged stage, while the adult pauropod has twelve postcephalic segments and nine pairs of legs. Emphasis is laid on the fact that the total segmentation of the pauropod, inclusive of its five head segments, is less than the total of twenty-one or twenty-two required to derive a machilid direct from a lower malacostracan or a leptostracan.

While all Progoneata appear to be anamorphic, and also many Opisthogoneata, there are also certain higher chilopods which, like the crayfishes, have telescoped all their larval segmentation stages into the egg, and hatch out with the full number of segments belonging to the adult. This phenomenon is termed *epimorphosis*. It is clear that epimorphic forms are, in this respect, more advanced than anamorphic ones.

* The complete new theory may be read under the title "The Evolution of the Class Insecta" (*Papers and Proceedings of the Royal Society of Tasmania*, 1930), which is an amplification of a presidential address on the same subject given in Brisbane in May last, before Section D of the Australasian Association for the Advancement of Science.

When we turn to the insects, we find that almost all of them are epimorphic, namely, the whole of the Thysanura and Pterygota. One small group, the Protura, still exists which exhibits anamorphosis; the larval form has nine abdominal segments, and three more are added just in front of the last, in the form of ring-segments, before the adult stage is reached.

This analysis now brings us to a hitherto neglected group, the Collembola or springtails. These differ from all other insects in having only six abdominal segments right through their embryology, their larval stages, and the adult. A close comparison can be made between this condition, which is really that of possessing *nine* postcephalic segments, and the twelve-legged larvæ of Pauropoda and Symphyla. It is suggested that this condition is even more primitive than that of the anamorphic groups, and should be distinguished as *protomorphic*.

We thus have three stages of evolution in segmentation of terrestrial arthropods: (1) *Protomorphism*, in which an original small number of segments is retained throughout the ontogeny; (2) *anamorphism*, in which this original number is raised, bit by bit, by addition of new segments near the hinder end at ecdysis; and (3) *epimorphism*, in which all this larval addition is telescoped into the embryonic period, so that the young larva hatches out with the full number of segments. The Collembola are claimed to be remnant of the original protomorphic ancestors or Protaptera; but for the fact that their abdominal appendages have been specialised to serve another function, that of jumping, instead of remaining as walking-legs, they could be classed as very primitive opisthogoneate myriopods. The Protura are a remnant of the later developed anamorphic groups of hexapods. The Thysanura must have begun as Entotrophica and later become more vigorous and developed exserted mouth-parts. The Pterygota or winged insects must have sprung direct from a dorso-ventrally flattened lepismatoid type.

The analysis of the walking-leg brings out two points. First, that there is no evidence of an undoubted exopodite in the legs or maxillæ of terrestrial arthropods, and therefore no need to derive insects from marine forms. Secondly, that the most primitive walking-legs are those of the Symphyla and Collembola, both of which are only actually four-segmented, ending in a claw and empodium.

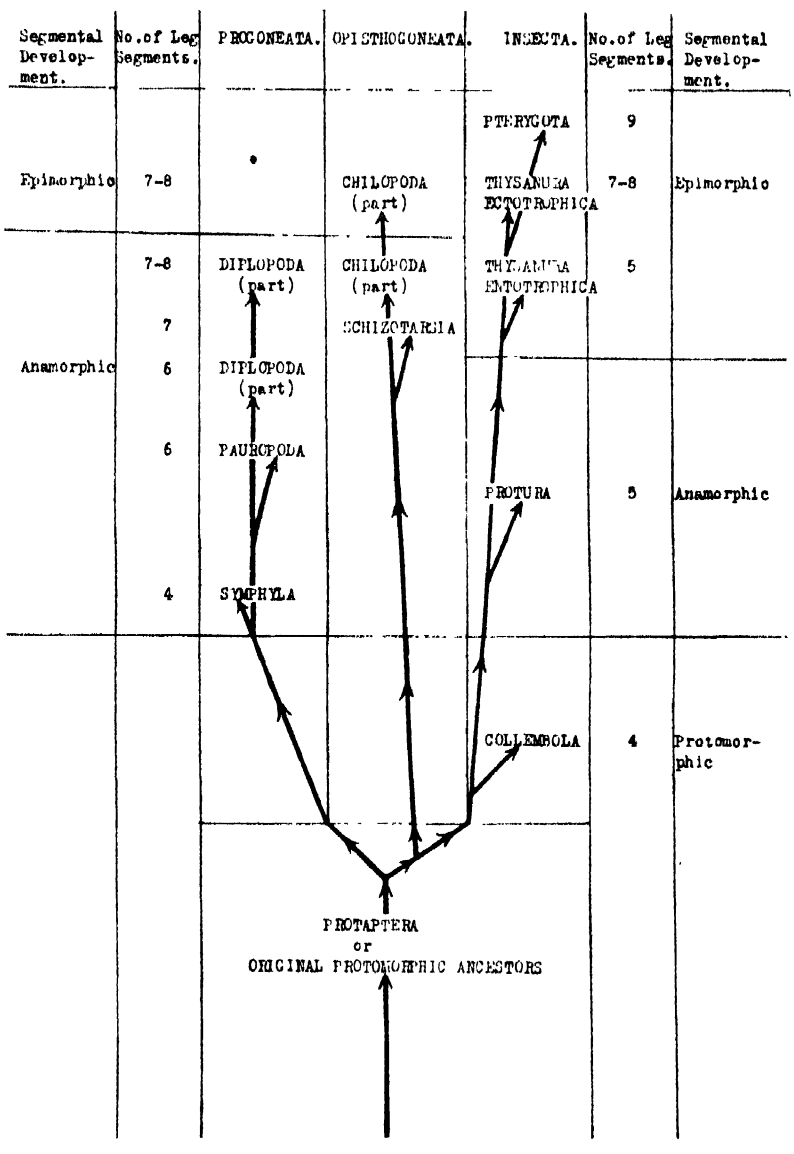

FIG. 1.

The abdominal styles and exsertile vesicles of the Thysanura are homologous with those of the Symphyla, both belonging to the subcoxal region. The legs of Collembola are even more primitive than those of Symphyla in not possessing either of these organs and also in the non-development of any definite scheme of chitinisation of the subcoxal region.

The evolution of the leg in Myriopoda may be followed out through stages with six, seven, and eight segments, that of insects through stages with five, seven, eight, and nine segments, the latter being the types having a tarsus with five divisions. The additional subdivisions do not take place similarly in myriopods and insects, and hence it is not allowable to homologise the separate segments above the original four in the two types.

Coming next to the crux of the reproductive system, and dealing first with the Japygidæ and the primitive Pterygota, we are led to the conclusion that the Thysanura-Pterygota line originally possessed eight pairs of gonads segmentally arranged, of which one pair has been lost in the

Japygidæ. Counting thoracic and abdominal segments all as postcephalic, the most posterior position of the gonopores in Progoneate types is the *fourth postcephalic segment*, while the most anterior position in Opisthogoneate types is actually the *eighth, in Collembola*. Thus both types can be simply derived from an original ancestor *which possessed only five pairs of gonads*, in the fourth to eighth postcephalic segments respectively. These must be conceived of as having originally opened segmentally by paired gonopores. The linking up of the gonads on each side by paired gonoducts, to open into the fourth postcephalic segment only, gave the primitive progoneate condition, while a similar linking, with backward opening into the eighth, gave the primitive opisthogoneate condition, as in Collembola.

The conclusions arrived at by the above three lines of analysis are so closely similar that it is possible to exhibit them all in a single phyletic diagram (Fig. 1). The original common ancestor of myriopods and insects must have differed from the Onychophora in not being epimorphic and in having fewer body segments. This common ancestor, the Protaptera, would have merited the status of a class. It divided, first of all, into progoneate and opisthogoneate forms; and, very soon after, the opisthogoneate types divided into Myriopoda Opisthogoneata and true Insecta or Hexapoda The Collembola are the only remaining remnant of all the ancient protomorphic types. They were quite well developed in the Lower Devonian. The progoneate types culminated in the higher diplopods, leaving the pauropods on one hand and the Symphyla on the other as lowly anamorphic types The opisthogoneate myriopods ran out into the higher Chilipoda, which are epimorphic; but, while still anamorphic, they gave rise to another highly evolved type, the Schizotarsia, with annulate legs and large compound eyes. The hexapod or insect line, leaving the Collembola and Protura far behind as lowly side-branches, ran rapidly through the Thysanura Entotrophica to the Thysanura Ectotrophica, and so to the winged forms of Pterygota, probably somewhere in the Carboniferous.

The probable geological horizon of the hypothetical ancestral Protaptera is Upper Silurian, and their ecology is that of terrestrial forms dwelling in moist places and feeding on primitive plant life.

Progress in Education and Research in Agriculture and Fisheries.

INCREASING recognition is being given to the fact that many problems connected with agriculture need the help of the trained research worker as well as that of the practical man. During the last twenty years, since the appointment of the Development Commission, steady and rapid progress has been made, until at the present time the ramifications of the system of research and advisory work set up by that body extend over a surprising variety of problems. Three reports recently issued, one by the Development Commissioners, and two by the Ministry of Agriculture on agricultural research institutes and research and education respectively, present a comprehensive picture of the existing state of affairs in Great Britain.

The report of the Development Commission* falls into four sections, the first two of which relate to the grants which have been recommended for the development of agriculture, rural economy, fisheries, and harbours, and describe the purposes for which these advances are being used. The third part of the report relates to action taken under Part 2 of the Act of 1909 in connexion with the compulsory acquisition of land for road improvements. The fourth part deals with the financial position of the Development Fund at the end of the year 1929–30. The advances recommended from the fund amounted to £721,653, as against £394,752 in the previous year. The large increase for agriculture and fisheries is attributable to recommendations for capital expenditure out of a special grant of £500,000 made for unemployment relief. Schemes relating to fishery harbours and reclamation are receiving special attention, and any economic schemes of reclamation which may be put forward will receive favourable consideration.

Among the activities of the Commission, those dealing with the development of the countryside make a wide appeal. Rural industries are being aided and developed in thirteen counties by means of grants to be expended according to local needs for the organisation of classes and the staging of exhibits at shows. Some counties now have permanent showrooms for exhibiting craftsmen's goods. The building of village halls is much encouraged by a system of loans which has now been thrown open to the whole country by the establishment of *ad hoc* committees in counties not having a community council. The success of the scheme is such that in the first three months of 1929, 279 villages made inquiries as to loans, and during that period fourteen loans, amounting in all to £3833, were approved.

Another feature of the year's work of the Development Commission has been the adoption of methods for the relief of the fishing industry by remission of debts and by reconditioning of harbours with the view of the development of fisheries. A total sum of £34,770 was recommended during 1929–30 for the maintenance of fishery research. The grants are for 'directed' researches, deliberately planned to find a solution of problems affecting the commercial fisheries, and 'free' researches, the object of which is to advance that knowledge of marine life in relation to its whole environment upon which the solution of practical problems ultimately depends. The fisheries section of the report sets forth much interesting information, and is calculated to surprise the average reader by the

* Development Commission. Twentieth Report of the Development Commissioners, being for the Year ended the 31st March 1930. Pp. 247. (London: H.M. Stationery Office, 1930.) 3s. 6d. net.

extent and variety of the attempts to improve our knowledge of matters appertaining to the important sources of food in river and sea.

The position of affairs relating to agricultural research is set out more fully in the report issued by the Ministry of Agriculture and Fisheries.* Here, again, it is obvious that a very wide field is being surveyed, and that a multitude of problems relating to agriculture in the widest sense are being probed. These investigations are nearly all carried out at the research institutes and at advisory centres, by specially appointed staffs. It is scarcely possible to give even the briefest outline of the activities of the stations, which range from every aspect of plant and animal growth in health and disease to problems of agricultural economics, engineering, food preservation, and transport. The main lines of research in progress are indicated in a series of short reports drawn up by the heads of the various institutes, but of necessity they can do little more than indicate the object of the experimental work and the more striking of the results already obtained. It is apparent that steady progress is being made and much valuable information obtained and disseminated, the output apparently being limited only by the staff and money available. The attempt to establish *Spartina townsendii* (rice grass) in Essex is interesting. The primary object is to prevent coast erosion, other considerations being the provision of a supply of seed to meet overseas demands and the establishment of a crop which could be used as an emergency feed for stock and to provide material for examining other economic possibilities of the plant. Attempts at overseas transport have shown that seed is unsatisfactory for long journeys involving passage through the tropics, but that cuttings can be successfully carried so far as Singapore if shipped in cool chambers between 30° and 40° F.

Fluctuations in the number of wild rodents are of importance on account of the economic effects of these animals on agriculture and forestry. The co-operation of numerous observers throughout the country has been enlisted to obtain data about cycles in numbers of field mice and squirrels, the cyclical variation being apparently affected by disease and by certain climatic factors as yet not properly understood.

The other report issued by the Ministry of Agriculture and Fisheries† indicates a gradual but steady expansion of the system of agricultural research and education in Great Britain, this being regarded as convincing proof that a genuine need of agriculture in the country is being met by this means.

Agricultural research owes much to the financial aid received from the Empire Marketing Board, which has facilitated considerable extension during the past few years. In 1929 the expenditure on research from all sources amounted to £19,694 on capital account and £288,012 for maintenance grants, more than half of the expenditure taking the form of grants to research institutes. The most important single development has been the formation of eight Imperial bureaux, which have been established in close connexion with existing research institutes. These deal with soil science, animal nutrition, animal health, animal genetics, agricultural parasitology, plant genetics (herbage plants and others), and fruit production. It already seems certain that the opportunities thus afforded for mutual interchange of ideas and information will benefit British agriculturists as well as overseas workers.

Attention is directed to the serious scarcity of students, trained in biological science, capable of filling the various posts in the Empire which from time to time offer themselves; special steps have since been taken to attempt to remedy this by increased publicity of the possible opportunities awaiting trained biologists.

The report, as a whole, confines its attention to an outline of the position of the Ministry's various activities with regard to agricultural research, local investigations and advisory work, scholarships, and provision of technical advice. Detailed accounts of the scientific results are not included, as they are published elsewhere.

Agricultural education during 1928–29 continued to make steady progress, but showed no features of outstanding importance. Special attention was devoted to the problem of providing suitable agricultural instruction for country boys and girls between the ages of fourteen and sixteen years, and certain experimental courses in Shropshire met with such success that the possibility of more extended schemes has come under consideration. Further success has attended the Ministry's recognition of farm household management as a branch of agricultural education, scholarships being provided at certain institutes.

Improvements in the position of veterinary science are overdue, and proposals have been put forward for the reconstruction of the Royal Veterinary College with the view of establishing the work on a sound basis, the recommendations being very far-reaching.

The progress of dairy education is reflected in the rapid improvement in the milk supply throughout England, the producer, on the whole, turning out a much higher grade product than formerly. As a result, the interest of sanitary inspectors has been aroused, and many of these are endeavouring to keep in touch with the dairy instructors.

Horticultural education is steadily increasing, and during 1929 two more county authorities began to provide facilities in this respect. A noteworthy advance has been made with regard to instruction in the cultivation of crops under glass, as complete courses of practical and technical instruction for the commercial glasshouse industry have been established by the Herts education authority, in co-operation with the Lea Valley Growers' Association. Bulb-growing provides an example of a

* Ministry of Agriculture and Fisheries, Department of Agriculture for Scotland, and Ministry of Agriculture for Northern Ireland. Reports on the Work of Agricultural Research Institutes and on certain other Agricultural Investigations in the United Kingdom, 1928–29. Pp. 247. (London: H.M. Stationery Office, 1930.) n.p.

† Ministry of Agriculture and Fisheries. Report on the Work of the Research and Education Division for the Year 1928–29. Pp. 100. (London: H.M. Stationery Office, 1930.) 1s. 6d. net.

highly specialised industry which is benefiting by county and Government assistance, comprehensive trials and experiments dealing with problems peculiar to the industry being carried out in various centres, notably Scilly, Cornwall, and Lincolnshire.

On the advisory side, continued progress has been made in the inspection and certification of growing crops, chiefly potatoes, strawberries, and black currants; of goods intended for export, including nursery stock; and in the enforcement of the various orders against destructive insects and pests. The value of this phase of work is enhanced by the stringent import regulations in force in many other countries, as it is most important that the high reputation of the English certificate of health should be maintained.

News and Views.

THE following sectional presidents have been appointed for the centenary meeting of the British Association, to be held in London on Sept. 23–30 next year, under the presidency of General Smuts: Section A (Mathematical and Physical Sciences), Sir J. J. Thompson; Section B (Chemistry), Sir Harold Hartley; Section C (Geology), Prof. J. W. Gregory; Section D (Zoology), Prof. E. B. Poulton; Section E (Geography), Sir Halford Mackinder; Section F (Economic Science and Statistics), Prof. E. Cannan; Section G (Engineering), Sir J. Alfred Ewing; Section H (Anthropology), Prof. A. R. Radcliffe-Brown; Section I (Physiology), Dr. H. H. Dale; Section J (Psychology), Dr. C. S. Myers; Section K (Botany), Prof. T. G. Hill; Section L (Educational Science), Sir Charles Grant Robertson; Section M (Agriculture), Sir John Russell. On Wednesday, Sept. 23, the ceremony of installing General Smuts as president of the Association, and a reception of delegates, will be held in the Albert Hall during a private view of the exhibition which is being arranged in connexion with the Faraday centenary celebrations, and will be open, for this occasion, to members of the British Association.

DYESTUFFS have occupied considerable attention in Parliament recently, the debates incidentally directing the limelight of public attention on to the part played by organic chemistry in framing the nation's destiny. In the House of Commons on Dec. 17, the Government's majority in favour of allowing the Dyestuffs (Import Regulation) Act, 1920, to lapse next month had fallen from thirty to six – a small number, seeing that 482 members voted, but sufficient to reject the amendment inserted by the House of Lords in the Expiring Laws Continuance Bill. Mr. Graham, the President of the Board of Trade, disagreed with the view that opportunity for further inquiry was necessary, holding that there has already been made a full and impartial review of the case by the Dyestuffs Industry Development Committee, which was representative of both dye manufacturers and dye users. This committee was unable to give any clear direction to the Government; the decision of the latter, he said, was well founded and should be maintained. Sir P. Cunliffe-Lister said that the committee's report urged the Government to pursue inquiries further and endeavour to reach agreement between makers and users as to the measure of protection necessary and the form which it should take. He challenged the Government to disclose the views of the Service departments, and declared that a substantial section of dye users opposed the lapse of the Act. Sir H. Samuel again opposed the continuance of the Act; is there any probability, he asked, that a new inquiry will lead to any more agreed and unanimous a report than that which has already been issued?

LABOUR members were not solidly ranged in support of the Government's attitude; Mr. Wise, Mr. Denman, Major Church, and Mr. Strachey advised acceptance of the Lords' proposal to continue the Act for one year. Mr. Wise expressed his belief that the growth of the dyestuffs industry in Great Britain has had very valuable effects on research, but he doubted whether all is being done that might be expected. It would be in the best interests of British industry and the vital interests concerned in dyes and chemicals if the Act were continued for a short period. Mr. Denman said that we need more experiment; we have shown ourselves intolerant of experiments and drop them at the moment when they are becoming interesting and worth continuing. He advised a test of the new conditions, followed by an inquiry, before a final decision was reached. Major Church said that virtually every scientific body in the country has condemned the non-continuance of the Act. With one accord eminent scientific workers at the Bristol meeting of the British Association last September suggested that it would be an act of incredible folly to withdraw the protection which has been given to our dye industry, and he did not think the House could afford to ignore the considered opinion of that body. Mr. Strachey declared that if Britain is to survive as an industrial nation, it will be primarily by the development and application of science throughout the industrial and economic system, and the action of the Government would attack the interests of science both directly and indirectly by allowing the Act to lapse. Speeches in favour of temporary continuation of the Act were delivered by Mr. Remer, Sir H. Croft, Mr. Marjoribanks, Mr. E. D. Simon, and Sir R. Horne, whilst Mr. J. H. Hudson, Sir D. Maclean, and Mr. Shaw opposed it; the Secretary of State for War (Mr. Shaw) admitted that the experts in his department advised that it is essential to maintain a chemical research industry, and that, failing it, there must be something comparable to safeguard the country.

INSISTING on its amendment, which has the effect of continuing the Dyestuffs (Import Regulation) Act for another year, the House of Lords on Dec. 18 returned the Expiring Laws Continuance Bill to the

House of Commons. It was admitted, said Viscount Hailsham, that dye-making is an industry of national importance, that the dye-makers are supported by the Institute of Chemistry and the Federation of British Industries in anticipating that lapse of the Act would check research and undermine the economic position, and that the Government's advisers on matters of national security consider that the lapse would be attended by danger. Lord Parmoor voiced the Government's protest, while Lord Darling reiterated that the question is one of the safety of the country. The subsequent debate in the House of Commons, which terminated with the acceptance of the Lords' amendment, disclosed little of scientific interest: it was concerned rather with views on the relations between the two Houses, with the organisation of the dyestuffs industry, with allegation and retort. The series of debates in Parliament has perhaps served a useful purpose other than that which necessitated it. The public has been reminded that organic chemistry stands in a unique and responsible position on the quarter-deck of the ship of State. Lip service at least, and perhaps a worthier tribute, has been rendered to the claims as well as to the achievements of research. All parties agreed that chemical research must go forward in support of industry and of defence; there were even references to the reasonableness of paying for such research as is desired. We hope that, in the comprehensive inquiry which will in due course be held, the voice of chemical science will be heard as attentively as that of economics.

THE birthday anniversaries of three veteran workers in science and educational progress are called to remembrance this month. On Dec. 12 last, Prof. W. C. Unwin, "a master and teacher of the science of engineering"—to use the appraising words of the late Sir William White—entered on his ninety-third year. He was born at Coggeshall, Essex, in 1838, educated at the City of London School, and began his notable technical career as a pupil in the firm of William Fairbairn, Manchester. Prof. Unwin was elected to the fellowship of the Royal Society in 1886. Dr. William Garnett, who was born at Portsea, will celebrate his eightieth birthday on Dec. 30. Like Prof. Unwin, he was educated at the City of London School. Proceeding to St. John's College, Cambridge, he graduated fifth wrangler. Entering the Cavendish Laboratory, Dr. Garnett enjoyed the distinction of being the first demonstrator of physics there under James Clerk Maxwell. From 1904 until 1915, Dr. Garnett was educational adviser to the London County Council. Prof. S. H. Vines, who was elected a fellow of the Royal Society in 1885, will be eighty-one years of age on Dec. 31. A graduate of Christ's College, Cambridge, he was formerly Sherardian professor of botany in the University of Oxford.

THE centenary of the birth of the British chemist, Augustus Matthiessen, which occurs on Jan. 2, recalls a career successfully devoted to science in spite of great physical infirmity, but one which came to a close all too soon, in tragic circumstances. Born in London, Matthiessen's life-long defect was due to a paralytic seizure in his infancy. From an early age, however, he displayed a taste for chemistry and at the age of twenty-one was able to go to Giessen, and later on to Heidelberg, working under Will, Buff, Bunsen, and Kirchhoff. Graduating Ph.D. at Giessen, he became known for his isolation of pure calcium and strontium by electrolytic means and for his study of electrical conductivity. Returning to London, he continued his studies under Hofmann, fitted up a laboratory at 1 Torrington Place, and from 1862 until 1868 was lecturer in chemistry at St. Mary's Hospital and after that lecturer at St. Bartholomew's Hospital. His work on electrical standards, undertaken voluntarily for the British Association, occupied the years 1862–1865, and in 1869 he was awarded a Royal Medal of the Royal Society for his investigations on the physical, electrical, and chemical properties of metals and alloys. For a year he was one of the editors of the *Philosophical Magazine*. He died on Oct. 6, 1870, at the early age of thirty-nine years.

A RECENT *Daily Science News Bulletin* issued by Science Service, Washington, D.C., gives a brief account of the meeting at Washington of the first Inter-American Conference on Agriculture, Forestry, and Animal Industry. At this meeting plans were discussed for protecting the great tropical forests of the Americas from careless exploitation such as has laid waste the forests of other parts of the world. It is estimated that there are some 3,000,000 square miles of forest lands in the twenty Latin republics, an area larger than the total area of continental United States exclusive of Alaska. Practically no research has been undertaken in these forests, and the estimate of the volume of timber they are said to contain (at least six thousand billion board feet) is admitted to be purely guess-work. Mr. W. T. Cox, consulting forest engineer of the Tropical Plant Research Foundation, said that "too little is yet known about the forests of tropical and sub-tropical countries". He urged extensive forest exploration aided by aeroplane, so as to obtain not only botanical information of the numerous trees but also commercial classifications. The training of young men in forestry and the development of these vast forests along scientific principles was advised.

INTERNATIONAL foresters heard something of the undeveloped state of the forests of the Latin Americas at the Forestry Conference at Rome in 1926. The proceedings of the Sub-Committee dealing with Tropical Forestry at that Conference show that there is a vast amount of information already gathered concerning some of the tropical forests, and the perusal of Stebbing's "Forests of India" would disclose the methods by which the tropical and sub-tropical forests of India and Burma have been brought under an intensive management during the past sixty years or so. At this Washington Conference other speakers dwelt upon the dangers of diseases and epidemics due to their accidental introduction, and to the necessity of organising this matter upon international lines. Prof. D. M. Matthews, University of Michigan, was more practical when he pointed out the dangers of

looking for temporary reward rather than to ultimate benefit when forests were cut down. He also directed attention to the degrade of the land which follows reckless exploitation, and the danger to agricultural areas. Others pointed out the necessity of studying the little-known or unknown timbers of this tropical forest area, "with a view to their possible uses in future decades when both Latin American countries and the United States will have to turn to these forests for most of their lumber". This shows a better realisation of the case, and the Conference to some extent grasped the present position.

THE executive of the Comité International Radio-Maritime at its meeting in Brussels in September last discussed the possibility of the transmission of pictures to ships by means of radio. On land, between fixed places, picture and facsimile reproduction is an accomplished fact, and Marconi engineers have obtained excellent results even when the places are thousands of miles apart. The technical and commercial experts recognise that such a service as the transmission of weather charts to ships' commanders for their guidance in navigation would raise considerably the factor of safety of navigation. They concluded, however, that it would be premature to undertake a service of facsimile transmission to ships at sea. Both technical and commercial difficulties stand in the way. In the present state of the system's development, the question of cost is a serious obstacle. Such a service would doubtless enable ships to make quicker voyages and appreciably reduce risk. It would supply the master of the ship with weather charts which would give him a visual indication of the weather conditions all round him. In order to justify itself, the service would have to be perfectly trustworthy and sufficiently accurate technically to ensure good reception. The apparatus, therefore, would have to be elaborate, and the weather chart service would cost probably not less than a guinea per day to ship-owners. The time occupied in the transmission of a weather chart would be about twenty minutes, during which the handling of the ordinary traffic would have to be suspended. The technical difficulties that are not yet overcome are the interference from other signals and atmospherics and, in addition, the phenomenon of 'fading'. These might render maps or charts illegible in parts and even misleading.

WHEN the English railway companies were first grouped together it was expected that more satisfactory results would be obtained by shareholders, passengers, and those who use the railways for the transport of goods. According to the views expressed by Sir Philip Dawson at a luncheon of the Batti Wallahs' Society on Dec. 11, "grouping has proved to be of no good whatever". The obvious thing for the railways to do is to adopt the most modern methods whatever they may be, but instead of doing this they do nothing. He believed that if they needed the money for the good of the public the Government would be willing to guarantee the amount. The investment would be quite sound. Unlike road and other employment schemes, it would pay dividends. The electrical manufacturers of Great Britain have supplied the world with the best machinery for electric traction. There is no reason why the country should not have the best equipped electric traction system in the world. Main line electrification has proved successful in Sweden, Japan, India, New Zealand, and many other countries. Actual electrification of the railway lines is easier now than it was a few years ago because of the progress that has been made with the grid. Sir Philip Dawson believes that main line electrification will soon be embarked upon, and that such electrification will become one of the great economic factors of the future. The Southern Railway has now 300 route miles electrified, making altogether 800 track miles. In spite of road competition, the increase in passengers carried during the last year was 35 per cent. This success is due to the fact that the comfort of the passengers has been studied. The services are fast and the trains sufficiently frequent to make the consulting of a time-table unnecessary.

THE success which has followed the introduction of high voltages for the distribution of electric power has led engineers to plan the use of still higher voltages. In Germany, for example, there is a closely meshed network 4700 miles in length working at 100,000 volts. In addition, Germany has now 750 miles of overhead mains operating at 220,000 volts. Even this high pressure is not considered sufficient to transmit great quantities of energy over hundreds of miles, and 380,000-volt lines are now being considered. At present the voltage economically practical is limited by the corona losses, but this limit can be raised considerably by employing suitable cables and insulators. To test the insulators which work at a pressure of 380 kilovolts, it is found that a voltage of a million is not adequate. In *AEG Progress* for December there is a description of a two-million volt laboratory which has been erected in the Porcelain Factory of Ph. Rosenthal and Co. As two million volts will arc over a distance of 16½ feet, a very large building had to be erected. It has no windows, as all the tests are carried out in darkness so that the faintest glow may be detected. On one side of the building there is a large hole, 27 feet in diameter, for leading out when necessary a two-million volt conductor. The high pressure is produced by two transformers with their secondaries in series and their primaries in parallel. The alternator has a capacity of a thousand kilovolt-amperes at a million volts. A large amount of power is thus available. The flashovers produced by this plant make a noise like the bursting of a high explosive, and physically are very similar to lightning. To measure the voltage, spherical electrodes each eight feet in diameter are used.

THE work of draining the Zuider Zee, the great national enterprise of the Netherlands, is now in full progress (NATURE, Sept. 21, 1929, p. 446). It is estimated that when all the land considered in the scheme has been reclaimed from the sea the area of the country will be increased by about one-seventh.

The first and smallest of the four areas into which the undertaking has been divided, and comprising nearly 50,000 acres, has been provided with two pumping stations, one at Medemblik and the other at Den Oever. When the area has been reclaimed, these stations will be permanently used for drainage purposes. In the *Brown Boveri Review* for November there is an interesting account of the novel electrical equipment at the Medemblik station. At Den Oever the water is pumped out by three centrifugal pumps driven by Diesel engines. At Medemblik the centrifugal pumps are driven by three-phase motors. The station is supplied with current at 50,000 volts. Each of the induction motors driving the pumps is rated at 660 kilowatts and runs normally at 107 revolutions per minute. By electrical devices, however, the speed can be varied between 88 and 120 revs. per minute, so that the operation may always be under the most favourable conditions. Owing to their slow speed, the motors had to be constructed with 56 magnetic poles. They always run at their maximum efficiency and power factor. The electrical station has been working continuously since last February.

ON Nov. 17, there was opened at the American Museum of Natural History a new South Asiatic Hall, the stocking of which was due to the enthusiasm of two British sportsmen, Lieut.-Col. J. C. Faunthorpe and Arthur S. Vernay. The hall is a fine tribute to the art of taxidermy in the Museum and to painstaking efficiency which led to the collection in India not only of the animals themselves but also of the plants, foliage, and representative sketches which combine to give a natural setting to the animal groups. The actual work of collection has been in progress since the first expedition was sent out in 1921, and the new hall itself has been in preparation during the last five years. The exhibited series consists of twenty large habitat groups showing all the more important of the Indian mammalia, but in addition the collectors brought back about 450 specimens now in the study collections. This fine gift- for the cost of the expeditions was borne by Mr. Vernay--arose from an almost chance visit paid by the late Col. Faunthorpe to the New York Museum, when, disappointed with the Indian animals exhibited, he expressed to Prof. H. Fairfield Osborn his willingness to make efforts to replace them. Needless to say, his project received every encouragement and support, and an unequalled South Asiatic Hall is the result. The official dedication of the hall was commemorated by the publication of a large brochure containing reproductions of photographs of all the groups. It should be a useful book to the enterprising museum curator, if only because it indicates suitable landscape treatment for the surroundings of different well-known species.

So often we have referred to the educational activities, amongst children, of certain American museums, that it is a pleasure to commend the excellent work being accomplished by some provincial museums in Britain. At the Cardiff Conference of the Museums Association in June, two papers were read on the subject of a rural museum service, pointing out what has been done, particularly at Batley and Huddersfield, and what could be done with further encouragement and help from education authorities (*Museums Journal*, November). The main theme centred round the distribution and circulation of specially prepared educational groups amongst schools; and the interest taken in the papers and in the subsequent discussion showed how keenly alive provincial museum curators are to the educational possibilities of their collections and to the need for making an impression upon young minds. In an editorial article upon the subject of rural museums for Britain, the school service is commended, but the remark is made that " it is hard to see why the teaching of children in (not from) elementary schools should be a function of museums ". Of course, the use of the museum should be a function of the education authority, but by hook or by crook the museums must get a footing in the world of elementary education, and the museums service to schools, apart from its own value, is a means of demonstrating to authorities slow to realise the possibilities that it is worth while to collaborate with museums.

A LARGE collection of neolithic implements from the Cotteswolds, numbering some eight thousand specimens, has recently been acquired by the Cheltenham Museum through the generous gift of Miss E. A. Paine. The collection was formed by her brother, the late Mr. A. E. Paine, who devoted many years of his life to the study of the neolithic period in that area. The collection is fully illustrative of the development of the new stone age industries of the district, and in addition to finished implements, includes flakes, cores, and fabricators, as well as implements in various stages of manufacture. There is also a representative series of polished implements, rare from this area. In an account of the collection which appears in the *Gloucestershire Echo* of Dec. 5, it is said that the collection is the finest from the Cotteswolds in existence. Incidentally, the writer of the article states that while the Museum contains objects from the long barrows of the neighbourhood, the culture of the round barrows is not represented, although it is well known that many of these have been opened and that their contents are still in existence but are not available for study. Perhaps Miss Paine's example may stimulate one or more private owners to emulate her generosity.

DR. MARCEL FOSSEYEUX, the indefatigable general secretary of the French Society for the History of Medicine, has recently compiled and published a bibliography, arranged according to authors and subjects, of the papers read before the first six international congresses of the history of medicine, held at Antwerp (1920), Paris (1921), London (1922), Brussels (1923), Geneva (1925), and Leyden and Amsterdam (1927) respectively. The great variety of the subjects is shown by the fact that they have been classified in the following fifteen sections: (1) bibliography, terminology, inscriptions, etc.; (2) education, schools and faculties, corporations;

(3) medical doctrines, methods, and processes of examination; (4) biographies (by far the largest section); (5) history of anatomy; (6) history of diseases such as plague, leprosy, syphilis, and nervous disorders; (7) surgery, obstetrics, ophthalmology, and stomatology; (8) pædiatrics; (9) dietetics, therapeutics, pharmacology, hydrology, and climatology; (10) public health and epidemiology; (11) veterinary medicine; (12) medicine and art; (13) medicine and literature; (14) hospitals, public assistance, and military medicine; (15) folk-lore, charlatanism, mystic medicine, popular medicine, and primitive medicine.

THE November number of the *King's College Hospital Gazette* was published as a centenary number and contains a sketch of the history of the Medical School, 1830-1930, the Medical Faculty having been established the year after the founding of the College. For some years the students suffered from the drawback of having to obtain practical instruction in the neighbouring hospitals, until in 1839 the first King's College Hospital was opened upon the site of the old St. Clement Danes workhouse in Portugal Street, Lincoln's Inn Fields. One hundred and twenty beds were at once available, and by 1872 this had increased to 172. In 1909 King Edward VII. laid the foundation stone of the new Hospital at Denmark Hill, which was opened four years later. Of the many famous men who taught in the old hospital, such as Richard Partridge (1805-1873), Robert Bentley Todd (1809-1860), Sir William Fergusson (1808-1877), Sir William Bowman (1816-1892), and others, Dr. Willoughby Lyle gives many interesting notes. Fergusson, a brilliant operator, it was said 'had the eye of an eagle, the heart of a lion, and the hand of a lady'. Lister joined the hospital in 1877, and it was in the old buildings in Portugal Street in July 1892 that he delivered his last clinical lecture. Patient to a degree, he disliked carelessness, but his failing was unpunctuality. The last meeting of the Committee of Management in the old buildings was held in July 1913, and patients were admitted and work commenced in the new hospital at Denmark Hill in October of the same year.

THE sixteenth Report of the Director of Veterinary Services and Animal Industry, Onderstepoort, Pretoria (Union of S. Africa, Dep. of Agricult.: The Government Printer, Pretoria, 1930. Pp. vi + 592), maintains the high standard of previous volumes and is admirably produced and illustrated. The Director, P. J. du Toit, and R. A. Alexander have found that it is possible to immunise horses against horse-sickness by means of formalised virus. The bacteria of botulism are surveyed at length by E. M. Robinson. Parasitology has several papers devoted to it. The important subject of mineral deficiency and metabolism as it affects animals is considered in seven communications. The production of bacon is the subject of a valuable study in which the influence of the breed of pig and variations in the feed of the animals upon the grade of bacon produced have been investigated. These papers are only a few of the studies dealt with in this volume.

AT the ordinary meeting of the Institution of Electrical Engineers to be held at 6 P.M. on Thursday, Jan. 8, an oil painting of Graham Bell, by Mr. W. W. Russell, R.A., will be presented to the Institution by Sir Hugo Hirst.

AT the recent council meeting of the Yorkshire Philosophical Society, York, Prof. G. Baldwin Brown, Watson Gordon professor of fine art in the University of Edinburgh, and Dr. R. Mortimer Wheeler, Keeper and Secretary of the London Museum, Lancaster House, were unanimously elected honorary members of the Society.

SERIOUS losses are liable to occur from certain diseases, particularly piroplasmosis and anaplasmosis, in British cattle imported into South Africa, South America, and elsewhere, and this risk acts as a deterrent to the export trade. The Ministry of Agriculture and Fisheries announces that immunisation against piroplasmosis and anaplasmosis can now be carried out at the Ministry's Veterinary Laboratory at Weybridge. For particulars application should be made to the Secretary of the Ministry, Whitehall Place, London, S.W.1.

WE learn from a recent *Daily Science News Bulletin* issued by Science Service, Washington, D.C., that quarantine restrictions on Florida fruit and vegetable shipments have been wholly removed as from Nov. 15 last. These restrictions were put into force in order to protect the rest of the United States against the Mediterranean frit fly which was discovered in certain Florida orchards in April 1929. Energetic measures of repression were put into operation almost immediately the discovery was made, and these appear to have been so efficacious that Florida is now restored to complete parity with all other States so far as such shipments are concerned. The lifting of the quarantine regulations, however, does not mean that the usual vigilance will be relaxed, since the possibility has to be provided for that complete eradication of the pest has not yet been achieved.

THE Medical Research Council announces that it has awarded three Dorothy Temple Cross Research Fellowships for 1930-31, these being the first appointments to be made under the terms of the recent benefaction in that name for research fellowships in tuberculosis, as follows: Dr. A. I. G. McLaughlin, Chief Assistant, Tuberculosis Department, St. Thomas's Hospital, London; Mr. R. J. Matthews, Chief Tuberculosis Officer, Mid-Glamorgan area, and Medical Superintendent, Cymla Hospital; and Lieut. S. M. Burrows, R.A.M.C., attached Sudan Defence Force. Dr. McLaughlin has received a fellowship for the study of methods of diagnosis and treatment at some chosen centre in the United States. Dr. Matthews and Lieut. Burrows have received senior fellowships and will make special studies of problems of tuberculosis among the native population in Zanzibar and in the Bahr-el-Ghazal Province of the Sudan, under arrangements made by the Council with the respective governments.

AN important catalogue (No. 440) of some 2000 second-hand books on zoology, geology, and palæonto-

logy has just been received from Messrs. Bernard Quaritch, Ltd., 11 Grafton Street, W.1. Many rare works are included.

MESSRS. A. West and Partners, 36 Broadway, Westminster, have recently issued a catalogue of 250 pages, of surveying and drawing instruments, with sections devoted to photographic apparatus and plan reproduction materials. Besides the usual apparatus and fittings, there are described a new form of cabinet for filing plans by hanging them in steel clips; a computing board designed by Mr. R. O. Kapp for calculations of two-part tariffs involving the four quantities—the kw. charge, the unit charge, the load factor, and the total cost per unit; and the Bromostat method of reproducing plans.

MESSRS. C. F. Casella and Co., Ltd., have recently issued a new edition of their illustrated Catalogue of Surveying and Drawing Instruments, including theodolites, transit instruments, levels, barometers, telescopes, tide gauges, planimeters, etc. Besides giving the dimensions and prices of the instruments, notes are given on their construction and, in some cases, on their use also. Included in the catalogue are the prism attachment for use with theodolites for the observation of equal altitudes, designed by Mr. E. A. Reeves, and the prism alidade, devised by the Rev. A. J. Potter, an instrument depending on a simple optical principle, which does not appear to have been used in this connexion hitherto. A new form of cathetometer is described; while among the barometers shown is an interesting reproduction of an instrument made about 1690 by Tompion, "the father of English clockmakers", who, it will be recalled, lies in the nave of Westminster Abbey, in the same grave as his famous apprentice, George Graham.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned: An assistant agricultural chemist in the Department of Agriculture and Horticulture of the University of Bristol—The Agricultural Advisory Office, 22 Berkeley Square, Bristol (Jan. 3). A visiting teacher of mathematics for the Paddington Technical Institute—The Education Officer (T.1), County Hall, S.E.1 (Jan. 5). A graduate assistant master for physics at the Middlesbrough Junior Technical School—The Director of Education, Education Offices, Middlesbrough (Jan. 5). A principal of the Torquay Technical College—The Secretary, The Castle, Exeter (Jan. 8). Civilian education officers, Grade III., in the Royal Air Force Educational Service—The Secretary, Air Ministry, Gwydyr House, Whitehall, S.W.1 (Jan. 17). A professor of geology at the University College of Wales—The Financial Secretary, University College of Wales, Aberystwyth (Feb. 14).

Our Astronomical Column.

Pluto.—As noted in NATURE for Sept. 27, Prof. M. Wolf found an image on a plate exposed at Königstuhl on Jan. 23, 1914, which was conjectured to be Pluto. A comparison made by Messrs. Bower and Whipple with their ephemeris in *Lick Obs. Bulletin*, No. 427, gave residuals of 112·5″, 25·2″ in R.A. and Decl., so that the identity appeared doubtful (*Harv. Circ.*, 142). But in *U.A.I. Circ.*, 305, Dr. Zagar publishes new elements of Pluto, in which he has applied perturbations by all the large planets, so that they should be somewhat more exact than the Lick elements (the difference between them is not great). The new elements represent the 1914 position within 0·6″, so that there is little doubt that it belongs to Pluto. It extends the arc of observation by nearly six years, the previous date of the earliest images being December 1919 (Mt. Wilson).

Prof. H. N. Russell discusses the orbit of Pluto in the *Scientific American* for December. He considers the resemblance to the predicted orbit of Prof. P. Lowell to be far too close to be ascribed to chance, and concludes that it is the planet to which Lowell's analysis pointed. He also makes some interesting comments on the relations of Pluto to Uranus and Neptune. It takes about 500 years for Neptune to gain a revolution on Pluto, so the two planets will not be so near to each other for 500 years as they were at the conjunction a few years ago. It will be some 9000 years before the two planets will be at their minimum distance from each other, which is about $2\frac{1}{2}$ astronomical units. Pluto comes slightly inside Neptune's orbit, its perihelion distance being 29·80 units, but its high inclination (17° 7′) prevents a very near approach. Zagar's date for the next perihelion passage is 1989 Aug. 28·72; Lowell predicted March 1991.

Masses and Rotations of Planets.—Mr. V. V. Narlikar, 136 Victoria Road, Cambridge, notes in a letter to the Editor that if the planets are arranged in order of angular velocity of rotation, we get nearly the same order as when they are arranged in order of mass, the larger masses having the smaller periods of rotation. He observes that this may throw some light on the origin of the planetary system, as the orbital speeds of particles near a large mass would be higher. It is doubtful whether much stress can be laid on his result. The difference of angular velocity of the four giant planets is very small compared with their difference of mass; further, Neptune, though more massive than Uranus, has a slower rotation. At least two of the inner planets, the earth and Mercury, have had their angular velocities diminished by tidal action, so that their present rotations are not much guide to the primitive ones. Still, the point is worth mentioning, as it may be one of the many factors on which the early rates of rotation depended. The masses of the asteroids are very small; still, many of them are inferred to have rapid rotations from changes in their light.

The Leonid Meteors. The date of the next expected maximum of the Leonid meteors is now approaching, being due in 1932 or 1933. The *Daily Science News Bulletin* of Nov. 18 and Nov. 21, issued by Science Service, Washington, D.C., states that the meteors this year were more numerous than was expected, the display being the best since 1901. Dr. Olivier states: "It was much better than we expected and greatly encourages us to think that there may be a great shower in two or three years". The maximum occurred on the early morning of Nov. 17, which was a day later than he expected; the hourly rate was two or three times as great as he expected, and many of the meteors were fire-balls with long-enduring trains.

It is extremely difficult to make accurate forecasts for meteors, as their orbits are not identical with that of the parent comet; further, those that we meet in any year have never been seen before, so we can only guess at their position, knowing that of other meteors at a considerable distance from them.

Research

Peruvian Weights.—In *Man* for December, Erland Nordenskiöld discusses the ancient Peruvian system of weights on the evidence of two collections of stones presumed to be weights. Although individual objects regarded as weights have previously been described, this is the first account of any series from which some idea of the Peruvian system might be deduced. The first series is from the collection of Dr. E. Gaffon in Berlin. It comprises 13 stones and was discovered in the Hacienda de Sagrario, near Huacho. With the series was a small beam balance and a basket-work case. The weights were enclosed in a neatly finished cloth bag. With one exception the weights are water-polished pebbles; the exception is said to be of meteoric iron. The stones fall into two series, one of four stones, the other of nine. When the series of nine is arranged according to weight, it appears that the heaviest is eighteen times the weight of the smallest, the intervening units being 3, 5, 10, 12, 15, and the aggregate sum of all the units 85. The weight of the smallest is 1·53 gm., of the heaviest 27·50 gm. In the series of four, the largest again appears to equal eighteen units of weight, weighing 29·17 gm., and the smallest five units, at 8·10 gm. This system appears to show Spanish influence. The author, however, believes he has discovered in the collections of the Gothenburg Museum a series which is uninfluenced by the Spanish system, in a number of stones contained in a cloth bag from Pachacamac. In this series of nine stones, five suggest a unit between 3·72 gm. and 3·86 gm., while the remaining four, if taken in pairs, probably constitute units in the same system. There again occurs a weight which is eighteen times the unit, and it is, therefore, suggested that the figure 18 in the previous system is a survival of the ancient and original system. It may be due to the necessity of measuring some compound in which one of the ingredients had to be eighteen times another—such, for example, as the proportion of copper to tin in making bronze (5-6 per cent of tin in the Inca bronzes).

Excavations in Syria.—The results obtained in 1929 and 1930 by the French archæological expedition to Syria of the Académie des Inscriptions et Belles Lettres are described by M. Schaeffer, the leader, in the December issue of *Antiquity*. The work was begun as the result of the accidental discovery of a burial vault at Minet el Beida which contained Mycenæan and Cypriote pottery dating from the thirteenth century B.C. The excavations on this site have revealed an important cemetery containing several large rectangular tombs with corbelled vaults, approached through a short vestibule with stairway, the whole being built of well-worked stone blocks. One of the tombs was hidden under an important building and other more important buildings connect directly with the tombs. One building cleared this year contained thirteen halls, rooms, and passages, without counting the upper story, the staircase and landing of which are preserved. North of the tombs, towards the sea, at a depth of between 0·50 m. and 1·50 m. lay about eighty deposits of Mycenæan, Cypriote, and local pottery, bronze implements, and a variety of other relics, some of Egyptian provenance, and including statuettes of Syrian and Egyptian deities. A large temple on the northern projection of the mound had two rectangular courts joined together and enclosed by thick walls. The name of the town, Sapounna, was recovered from one of the stelæ. Near by was a seminary for priests, equipped with a library with numerous inscribed tablets. Outstanding importance is given to the cuneiform tablets by the fact that most of them contain a script that is wholly unknown and had already become alphabetic. In the glossaries Sumerian is translated into a language at present unknown, instead of the usual Babylonian. From the important finds made to date, it is clear that Sapounna was an international commercial centre of first-rate importance, with a polyglot population whose priests must have spoken at least five languages, including that which is at present unknown to us; while in the pantheon, native Syrian deities appear side by side with those of Mesopotamia and Egypt.

Abnormal Incisor in a Coypu.—An abnormal incisor of *Myocastor coypus*, which recalls some of the examples in other mammals recently described by Prof. W. C. M'Intosh, is described and figured by Carlos Ruscom (*Physis: Rev. Soc. Argentina Cien. Nat.*, **10**, p. 162; 1930). In the degree of its abnormality this upper tooth is unusual, for, having been deflected off the line of its opposing incisor in the lower jaw, it has continued to grow until the tip has described a full circle and more. The usual length of the incisor of a coypu is 76 mm.: this one measures 156 mm.

Fresh-water Sponges from the Dutch East Indies. Mr. N. Gist Gee, in *Treubia* (vol. 12, 1; 1930), continues his work on fresh-water sponges, the first part of which contained an historical account (*Treubia*, vol. 11, 2; 1929). The present part provides descriptions and illustrations of a very large number of species. Fresh-water sponges are abundant in these regions, occurring in lakes, tanks, ponds, and running water, and many of them are described from living material; this gives much value to the work, for colour, form, and habit are specially noted, in addition to the spicules both of the sponge itself and of the gemmules. We have now a very good idea of the fresh-water sponge fauna of the Dutch East Indies, which is of considerable importance.

North American Retinellidæ.—After careful study of the anatomy of most of the species, H. B. Baker has attempted to classify the North American land snails of the genus *Retinella* (*Proc. Acad. Nat. Sci. Philad.*, vol. 82). Previous classifications based on the supposed presence or absence of an accessory left mantle-lappet are inaccurate, the structure being present in all. It seems that *Retinella*, *Glyphyalinia*, *Omphalina*, *Mesomphix*, and *Vitrinizonites* have two widely separated lappets on the left side of the mantle edge, but *Oxychilus* and *Zonites* have only one continuous lappet in that position. The shell characters that may be used for the distinction of species are growth sculpture, spiral striæ, and form of shell. A systematic list with localities and notes of the species of the genus form the bulk of the paper, which also includes descriptions of the new subgenera *Glyphyaloides* and *Glyphognomon*.

The Foraminiferal Family Polymorphinidæ.—In "A Monograph of the Foraminiferal Family Polymorphinidæ, Recent and Fossil" (*Proc. U.S. Nat. Mus.*, vol 77, pp. 1-195, pls. 1-40; 1930) Dr. J. A. Cushman and the late Dr. Y. Ozawa describe and figure all the species of the Polymorphinidæ. The first undoubted representatives are found in the Trias, but it is not until the Jurassic that the family becomes at all frequent. The affinities of the species which have been recorded from the Ordovician and the Devonian are uncertain. With regard to distribution, the authors state that smooth and rather primitive species have a long geological history and are widely distributed, whereas specialised forms are restricted to narrow limits both in the present oceans

and in the past. Similarly, some of the species of various genera that are highly ornamented or have very characteristic shapes do not range widely. In their remarks on the evolution of the family, it is stated that the Polymorphinidæ are certainly derived from some coiled form of the Lagenidæ such as *Marginulina* or *Vaginulina*. Many species are described or recorded from various horizons in the Jurassic, Cretaceous, and Tertiary formations of England.

Researches on *Caudina chilensis*.—This organism is a favourite subject for research, and is used in two interesting papers in the June number of the *Science Reports* of the Tôhoku Imperial University (Fourth Series—Biology), Sendai, Japan, vol. 5, No. 2, 1930: "Notes on the Development of a Holothurian *Caudina chilensis* (J. Muller)", by Densaburo Inaba, and "On the Circulation of the Perivisceral Fluid in *Caudina chilensis* (J. Muller)", by Masayasu Zazabi. The first describes the development from egg to larva and young stages, the work being carried out both on material reared from artificial fertilisations and on eggs and larvæ from the plankton. The Auricularia stage is omitted and the barrel-shaped larva is a Doliolaria, which is also the case in several cucumarians the development of which is known. The life-histories of members of the family Molpadiidæ, to which *Caudina* belongs, have not so far been investigated, and it is shown that it is more closely related to the Cucumariidæ than to the Holothuridæ or Synaptidæ. The breeding season at Asamushi, where the work is carried on, is in May and June, spawning taking place during the high tide which succeeds the day-time low tide. The structure of all the stages in development is carefully worked out and there are good diagrammatic text-figures and six plates. The second paper, dealing with the pericardial and the tentacular fluid in *Caudina*, shows that the current of the former progresses antero-posteriorly close to the body wall and returns postero-anteriorly along the centre of the body cavity. The pressure of the perivisceral fluid exhibits much variation and is much higher in adults than in the younger animals in a similar physiological state.

Genetics of Garden Beans.—There are many varieties of the garden bean, *Phaseolus vulgaris*, differing markedly in the colour and mottling of the seed, in flower colour, and in other characters. K. Miyake, Imai, and K. Tabuchi (*Jour. Coll. Agric. Imp. Univ. Tokyo*, vol. 11, No. 1) have made a further study the genetics of stem and flower colour, seed-coat colour, and pattern. They find pink stem recessive to red, the flower colour corresponding in each case, while green stems may bear flowers which are red, pink, flecked, or white. Varieties with flecked or white flowers always have green stems, but when these are crossed the stem is coloured. Red stem is epistatic to pink, and coloured stem is dominant to green. Pink × green stem gives red F_1 and in F_2 9 red : 3 pink : 4 green, showing the presence of two factors. As regards seed colour, black is found to be epistatic, and white hyperstatic to all others. Intermediate in the series are brown, purple, red, grey, and yellow, each apparently represented by a single gene. Piebald is recessive to self-colour, and there are three possible modifiers affecting the extension of the colour. The 'mottled' character is dominant and is linked to the recessive gene cream, with which it gives 2·6 per cent of crossing-over. The various types of bean studied are illustrated by two coloured plates.

Base Line Comparisons.—The Baltic Geodetic Commission has recently issued its first Special Publication (No. 1, Helsingfors, 1930, pp. 236), which is entitled "Measuring of Seven Base Lines of the Baltic Polygon, executed in the year 1929", by Ilmari Bonsdorff. The aim was to determine whether the base lines in the various countries surrounding the Baltic Sea, and partaking in the work of the Geodetic Commission, are really in agreement with one another. The seven base lines chosen were Szubin (5·1 km.) in Poland, Sveksna (6·5 km.) in Lithuania, Ösel (6·3 km.) in Estonia, Hanko (5·9 km.) in Finland, Enköping (6·9 km.) in Sweden, Öland (6·0 km.) in Sweden, and Lolland (6·8 km.) in Denmark; these were compared with the standard bases at Potsdam (240 metres) and Helsingfors (720 metres). Eight invar wires were used; four were Finnish and four Danish, and as their certificates indicated that their temperature coefficients were different, they were supposed to be drawn from different pieces of invar; it was found later that one set of certificates gave wrong values, and that all the wires were really drawn from the same piece. Afterwards it appeared that between the second and third measurements at Helsingfors all the eight wires lengthened by 0·082 mm., for no assignable cause. This seems to be the most serious cause of error in such geodetic measurements, apart from irregular lateral refraction depending on climatic conditions.

Echo-Sounding.—The depth shown by an echo-sounding machine requires correction for the slope of the bottom, since the strongest echo, which makes the record of the depth, is returned as a rule from the nearest point, which is not always vertically under the ship. A. L. Shalowitz (Slope Corrections for Echo Sounding: U.S. Coast and Geodetic Survey Special Publication, No. 165) considers that this correction is negligible if it is so small that the uncorrected sounding would be correct if displaced on the chart by a distance not greater than the width of the numerals expressing it, 0·16 inch on an American chart, and provides tables for the rapid recognition of such cases. At least two lines of soundings are required in order to determine the slope correctly. An objection to this suggestion is that a sounding would be entered uncorrected on a chart on a small scale but corrected on one on a larger scale. The paper is reprinted in the *Hydrographic Review*, vol. 7, No. 1 (Monaco 1930), which contains a number of original papers and reprints or abstracts from other journals. Among the original papers is a note, with illustrations, on the British Admiralty pattern echo-sounders for 250 fm. and 500 fm., made by Henry Hughes and Son; and in other papers reference is made to the Langevin echo-sounding apparatus used in Italian surveying ships, and the French Marti apparatus. E. Lübeke in a reprint recommends the use of the Admiralty "Tables of the Velocity of Sound, etc.", H.D. 282, for the reduction of soundings to be used for scientific purposes, but prefers a standard velocity of 1500 metres per second for practical purposes. M. Camille Vallaux discusses the present state of our knowledge of the Humboldt Current, and accepts the view that the cold greenish water rich in diatoms wells up from the continental slope, while the occasional patches of cold blue water come from greater depths. Capt. J. Luymes, of the Netherlands Hydrographic Office, gives a short history of oceanography, with a postscript dealing with the work of the *Willebrord Snellius* Expedition up to the end of the year 1929.

Fluid Flow at Corners.—The issue of the *Canadian Journal of Research* for September contains a contribution from the National Research Laboratories, Ottawa, dealing with the design of corners in fluid channels so that they may produce the minimum of disturbance of the uniformity of flow. The authors, Messrs. G. J. Klein, K. F. Tupper, and J. J. Green, by observations on the air flow in a wind tunnel 18 inches wide, bent at a right angle, find that strips of thin

metal a little more than an inch in width bent so that half their width is at right angles to the other half, and placed in the diagonal of the bend of the wind tunnel with their surfaces parallel to the two directions of flow, make a great improvement in the uniformity of the downstream flow. Strips of the same width bent so that their transverse section is a quarter of the circumference of a circle, and placed about half their width apart along the diagonal of the bend, produce a downstream flow which is very nearly uniform across the width of the tunnel. The authors point out that the same improvement may be made in the uniformity of the downstream flow in bent water- or steam-pipes in which the resistance has to be reduced to a minimum, by the introduction of bent vanes.

Joule's Thermometers.—The November issue of the *Journal of Scientific Instruments* contains a short note by Dr. J. R. Ashworth on the present state of two of the thermometers used by Joule in his researches on the mechanical equivalent of heat which are preserved in a wall case in the rooms of the Manchester Literary and Philosophical Society. The two are the *A* and *D* instruments mentioned by Joule in his paper in the *Transactions* of the Royal Society of 1850 as those with which his most accurate work was done, *A* being the calorimeter thermometer. Each was made by Dancer of Manchester in 1843, and is nearly a metre in length, with a spheroidal bulb and an arbitrary scale, the range of *A* being from 0° to 30° C., and of *D*, 0° to 100° C. Joule calibrated both and recorded the changes of the freezing-point readings on them from 1844 to 1882. Sir Arthur Schuster tested them again in 1892, 1893, and 1894, and Dr. Ashworth has again tested them this year. During the whole period the freezing-point records have risen; in the first six years *A* showed a rise of 0·33° C., and it is now 0·65° C. and appears to be approaching a limit exponentially. It would be interesting to know what other thermometers of this age are in existence, and how their freezing-point readings have changed since they were first determined.

Sulphur Hexafluoride.—The compound SF_6, discovered by Moissan in 1886, is of interest because in it sulphur is exerting its maximum valency and the resulting compound is chemically very inert. Shumb and Gamble, in the November number of the *Journal of the American Chemical Society*, describe the preparation of the compound from sulphur and fluorine (the only practical method), in the course of which they give details of a simple apparatus, in which monel metal was used, for the production of fluorine. The vapour-pressure curve, melting point (−50·8°), and gas density (5·10 when air = 1; theoretical 5·04) were investigated.

Oil-driven Locomotives.—To the valuable series of pamphlets issued by the Association of Engineering and Shipbuilding Draughtsmen has recently been added one on the internal combustion engine, by B. Reed. In England, America, Germany, Switzerland, Russia, and elsewhere, much experimental work is being done on oil-driven locomotives, and Mr. Reed's paper contains a review of the problems involved in the design of locomotives fitted with Diesel engines and many particulars of the oil-driven locomotives at work. The fuel consumption of a Diesel engine for traction purposes is about 0·43 lb. per b.h.p. per hour, but taking coal at 22*s*. 6*d*. per ton and Diesel oil at 90*s*. per ton, the thermal efficiency of the oil-driven locomotive must be at least 3·1 times that of the steam locomotive for there to be no increase in the fuel bill. Included in the pamphlet are tables of costs, curves of performance, sections devoted to the locomotive as a whole, the engine unit, and the various forms of transmission gear, while an appendix gives details of eight recent engines and a bibliography of articles on the subject published in the engineering Press. Like other publications of the Association, the pamphlet is obtainable from the Draughtsman Publishing Company, Ltd., 96 St. George's Square, S.W.

Utilisation of Waste Wood Chips.—At St. Helens, Oregon, an extensive plant has recently been put into operation by the Fir-Tex Insulation Board Co. for the conversion of the hitherto wasted Douglas fir chips from the lumber industry into board one inch thick for building and insulation work. An illustrated description of the plant by R. C. Smith appears in *The Valve World* for November 1930. The chips, of which the supply is almost unlimited, are first treated with steam, in 18 ft. spherical rotary digesters, and then are reduced to pulp by hammer shredders. From the storage chests the pulp is passed on to a Fourdrinier machine having a wire screen 13 ft. wide and 100 ft. long with eight presses, each with two rolls, the main rolls weighing 12 tons each. The board, emerging from the machine at the rate of about 20 ft. per minute, is automatically cut into lengths and is then passed to a drier 360 ft. long with eight decks heated by oil-burning furnaces. The plant is capable of producing 150,000 sq. ft. of one-inch board every 24 hours, but plans are already under consideration for the extension of the plant to ten times this capacity. The board has not only been used for building and refrigeration work but also tests in the sound studios at Hollywood have shown it to possess remarkable acoustic and sound-deadening properties.

Cooling Electrical Machinery.—After forty years' experience in the design of electrical machinery, engineers have found that the heating factor is the one which nearly always limits the size of electrical apparatus. The temperature rise of machinery in the early days was very difficult to guess, but now that the conductivity of insulating materials and the laws of the loss of heat by air convection currents are known, approximate values for this rise are easily found. The maximum permissible temperature rise of any portion of a machine, the so-called hot spot temperature, is determined by the standard specification. Unfortunately, it is difficult to get international agreement on permissible temperature rises. They naturally depend on permissible overloads and these vary in different countries. In Britain, for example, the maximum permissible temperature rise for the commutators of very small motors is 45° C., in America 65° C., and in Germany 60° C. As the overload conditions are often different, it is difficult to compare the relative value of home and foreign machines. In a paper read to the Institution of Electrical Engineers on Nov. 6, Mr. Hoseason described various methods of heat dissipation and compared their relative values. The cooling medium most frequently used is air. Large generators and motors generally work with a ventilating air circulation system closed on itself with a water-cooler in the path of the air. In these cases the heat passes from the surfaces of the hot parts into the circulating air, is conveyed to the water in the cooler, and then carried by an outlet into a pond or river. Hydrogen is now not uncommonly used in place of air in the closed circuit, on account of its high thermal conductivity and the less power required to keep it circulating. In air-cooled machines it is found necessary to circulate about 100 cubic feet of air per minute per kilowatt lost, and in water-cooled machines about a gallon of water per minute for the same loss.

Biological Control of the Greenhouse White-Fly.

By E. R. SPEYER, Entomologist to the Experimental and Research Station, Cheshunt.

THE greenhouse white-fly is a pest of a number of plants grown under glass, and has, during the past fifteen years, become so widely distributed in Great Britain, Ireland, and the Channel Islands that the owner of the smallest conservatory must by this time be familiar with it and with the sordid appearance of his plants when infested by this insect.

Through the researches of Dr. Ll. Lloyd at the Cheshunt Experimental Station in 1920, it was shown that the pest could be controlled in commercial tomato and cucumber nurseries by fumigation either with the cheap 'cyanide' process or with the vapour of the more expensive liquid, tetrachlorethane. His demonstration of the correct methods of fumigating so as to reduce injury to the tomato plant to a minimum resulted in an incalculable saving to the industry.

In spite of the comparatively widespread use of these fumigants, the general white-fly population continued to increase in subsequent years, the commercial grower began to realise certain difficulties connected with extensive fumigation, and certain varieties of greenhouse plants were found to be very seriously injured by the vapour of tetrachlorethane.

The appearance of a parasite enemy of white-fly in Surrey was recorded by the late Prof. H. Maxwell-Lefroy, but the habit of this particular species, which still exists in England, does not admit of its exercising any material measure of control over the pest. An allied hymenopterous parasite, *Encarsia formosa*, was found by Mr. L. Hawkins at Elstree, Herts, in 1926, and scales of white-fly, parasitised by this insect, were received at the Cheshunt Experimental Station through the *Gardeners' Chronicle*. Observations upon the habits of the parasite established the facts that it reproduces itself parthenogenetically; is capable of distributing itself quickly by flight not only within an area covered by glass, but in midsummer for distances of several miles over land interspersed with greenhouses; and that a complete control of white-fly infestation is obtained by it when warm temperatures prevail.

Anything approaching extermination of the pest within a short period of time could not be expected, as the parasite is entirely dependent upon the young stages of white-fly for its existence, and cannot survive the winter either out-of-doors or in unheated greenhouses. However, the results of distribution during the summer of 1927 were so promising, that an application was made to the Empire Marketing Board, which generously gave a grant for the erection of a glasshouse in which the parasite could be propagated upon a larger scale.

During the earlier investigations upon the breeding habits of the parasite, an important fact came to light, namely, that the percentage parasitisation of white-fly scales is not the same upon all types of plant. The tobacco plant in particular, when grown in small pots, produces a sticky foliage upon which the white-fly breeds readily, but to which the parasite shows some aversion. It is due to this fortunate circumstance that a stock of white-fly can be maintained so that a continuous supply of parasitised scales upon other plants is obtainable.

The method of distribution is simple and has been adhered to as being the best with which to establish the parasite in greenhouses. Tomato plants are grown in pots or in the ground; tobacco pot-plants infested with white-fly and with a certain number of parasitised scales upon them are introduced amongst the former. The white-fly soon distribute themselves and lay eggs upon the lowest branches of the tomato plants; the scales which result from these eggs readily become parasitised and are recognisable by the jet-black colour which they assume 11-14 days after each has received a parasite egg. This blackening marks the time at which the pupal white-fly is destroyed by the larva of the parasite within the scale-case. When a large number of black scales have made their appearance, the low branches are removed, packed in boxes, and sent out to the grower, who ties them into small bunches and hangs them about in his infested house for a period of three weeks, during which time the parasite larva pupates and finally emerges, through a hole which it cuts in the roof of the scale-case, as the adult winged parasite, which immediately begins to deposit eggs in white-fly scales in its new environment.

In the meantime, more white-fly have bred upon the now lowest branches of the original tomato plants, which are afterwards used as another supply for distribution, and so on. A single series of tomato plants will thus yield a continuous supply of parasites for several months if transferred to 12-inch pots when young or when grown in the ground. At least a thousand parasitised scales may be present upon a single tomato branch, and each parasite eventually emerging is capable of causing the subsequent destruction of some fifty white-fly scales.

Male parasites appear rarely and usually only when temperatures have fallen below 60° F. over a period of some weeks. Under such conditions the fertility of the female may be much reduced. Adults of both sexes measure rather less than $\frac{1}{40}$ in. in length, so that they are not readily noticed unless very large numbers are present.

The approximate number of parasitised scales distributed in this way to growers of glasshouse plants during the past four years may be of interest:

Year	Approx. No Distributed.	Recipients.	Localities.
1927	15,000	13	5 English 1 Welsh County.
1928	200,000		20 Counties, England and Wales.
	20,000		Royal Botanic Gardens, K
	20,000		Canada.
	10,000		Channel Islands.
Total	250,000		
1929	900,000	509	40 English Counties.
	20,000	28	Wales.
	30,000	14	Scotland.
	20,000	11	Ireland.
	100,000	16	Channel Islands.
Total	1,070,000	578	
1930	1,350,000	745	42 English Counties.
	40,000	38	Wales.
	50,000	16	Scotland.
	10,000	6	Ireland.
	50,000	22	Channel Islands.
Total	1,500,000	827	

Up to May 1930, boxes of parasites were distributed to applicants free of charge, but afterwards a charge had to be made to defray the cost of packing, etc., except to members and associates of the Nursery and Market Gardens Industries Development Society, Ltd., which controls the Cheshunt Experimental

Station. After this system was adopted, the number of applications fell off, so that the supply of parasites available exceeded the demand.

In 1928 reports were received from the majority of the recipients as to the measure of control which the parasite had effected. Apart from a negligible number of cases in which the parasite failed to establish itself, about half reported complete and the rest partial control. Owing to the numbers supplied, it was impossible to obtain similar information in later years, but many reports of complete control have come to hand from all quarters.

The working of the parasite is best judged of from tomato-houses in the Lea Valley, in some parts of which the pest has been extremely severe for many years. In these particular areas, it has been found unnecessary to make use of fumigants during both the last and the current year.

The very large number of parasites which continually escape from the breeding house at Cheshunt appear to have furthered the distribution of the beneficial insect throughout glasshouses in Hertfordshire, and the white-fly population of that county, in which there is almost as great an area of glasshouses as in the whole of the rest of Great Britain, has definitely been reduced to a small fraction of what it was five years ago.

Applications for white-fly parasites should be made to the Experimental and Research Station, Cheshunt, Herts, not later in the year than September, nor earlier than March, unless minimum night temperatures of 55° F. can be maintained in the greenhouse during the winter months. Particulars of charges, etc., will be forwarded immediately to applicants.

It is useless to introduce the parasite into greenhouses in which the white-fly is not breeding at the time of receipt of parasite material. The parasite is quite harmless to vegetation and to animals, and does not parasitise insects other than the white-fly. In cases of severe infestation, when immediate control of white-fly is demanded, the greenhouse may be fumigated with a half dosage of 'cyanide' or tetrachlorethane without injury to the parasite, which is also not materially affected by other fumigants and sprays generally used for the control of pests upon living glasshouse plants, with the possible exception of paraffin emulsion.

An illustrated account of the white-fly and its parasite was published in the *Journal* of the Royal Horticultural Society, vol. 54, part 1, p. 181, January 1929, and a detailed account of the life-history of *Encarsia formosa* appeared in the *Bulletin of Entomological Research*, vol. 18, pt. 3, p. 301, March 1927.

Current Mortality Rates.

THE recent inaugural addresses by Mr. H. M. Trouncer at the Institute of Actuaries in London and by Mr. Steuart E. Macnaghten at the Faculty of Actuaries in Edinburgh, besides dealing with certain technical matters, discussed subjects of more general scientific interest, and directed attention to the great decrease in the rates of mortality between ages 20 years and 70 years in the general population, and presumably also among the lives assured by the various companies in Great Britain.

Mr. Trouncer mentioned that it is common knowledge to insurance offices that investigate their own experience, that, apart from yearly fluctuations, the rates of mortality are now lighter than ever before. The two actuarial societies have in hand a new continuous investigation into the mortality experience of assured lives and annuitants, and while results with regard to the latter have already been published, with forecasts of future mortality and extensive tables, the work on assured lives has taken longer to arrange and the results for the three years 1924–26 will only be fully available early next year, but will be quickly followed by a further three years' experience. This last point is important, as there might be a danger in using the figures of three such light mortality years as 1924–26.

Mr. Macnaghten referred also to research into the effect of family and personal history and occupation and foreign residence on mortality and sickness, and reminded his audience that, a few years before the War, Mr. Lewis P. Orr delivered a valuable address on this subject and advocated that a bureau of research should be set up. The idea was received favourably and we have reason to believe that a scheme was actually worked out in a preliminary way and put before the insurance offices. Then the War came and all such work had to be put aside. In spite of various post-War difficulties, much has already been done to bring mortality statistics up-to-date, and it remains for the future to show how far the work can be extended to special classes of risk, as has been possible in the United States, where the War interfered less.

It would seem that an investigation into the mortality of assured persons who proceed to tropical or sub-tropical areas is required, and there is no doubt that the information at present available is incomplete and untrustworthy, though individual actuaries have done something to fill the gap, as, for example, Mr. H. E. Raynes, for East and West Africa. The risk in all such cases has decreased: mainly owing to the great advances in tropical hygiene and preventive medicine, though a little of the apparent improvement may be attributed to a wiser choice of the men sent abroad.

Mr. Macnaghten amused his audience by an example of the change in point of view. "It is difficult", he said, "to realise to-day that eighty years ago lives resident in the United States west of the Mississippi were not accepted for life assurance except on almost prohibitive terms." With a further improvement in conditions, with greater knowledge of how to live in unhealthy areas, and with accurate statistics to measure the risk, it is to be hoped that those who look back in future years will notice similar changes.

The British Industries Fair.

THE Committee which was appointed by the President of the Board of Trade in February 1930, under Lord Chelmsford as chairman, to examine the present situation of the British Industries Fair and to consider means of increasing its utility to British trade, in its report (London: H.M.S.O. Cmd. 3726. Price 6*d*. net) makes the basic recommendation that "the Fair should be developed so as to become a truly national manifestation of the quality and range of British products and an increasingly powerful factor in the expansion of our trade". Both Government and manufacturers generally should accord it more vigorous support, and the public should be encouraged to learn through the Fair that British

manufacturers can supply their needs. A policy of 'Sell British Goods' is at least as important as 'Buy British Goods', if for no other reason than the difficulties at present encountered by customers wishing to purchase British goods—difficulties which, in some cases at any rate, are due to the obvious reluctance or indifference of the retailer to sell British goods.

The British Industries Fair is the direct outcome of the measures taken by the Commercial Intelligence Branch of the Board of Trade, immediately after the outbreak of War in 1914, to deal with the situation which had arisen in many industries owing to the cessation of trade with enemy countries. From the first Fair, which was held in May 1915, in the Royal Agricultural Hall, London, with an exhibitors' floor space of 80,000 square feet, the size of the Fair has steadily developed; the Birmingham Section was started in 1920, and in the 1929 London Fair the area occupied by exhibits was more than 310,000 square feet. Since 1926 the Treasury has made a grant of £25,000 per annum for advertising purposes, but the Committee reports that it received overwhelming evidence that this sum was totally inadequate for effective world publicity, and recommends that the Government should establish a regular annual publicity grant of a minimum of £100,000 and recognise the Fair as an integral feature of British economic policy. The Committee agrees with the view that advertisement of the Fair abroad is of value to British industry generally, and records its conviction that expenditure of this character, by assisting the restoration of prosperity to British industry, will prove to be a national economy and be amply justified by results. The preponderance of evidence was emphatically against increasing charges for space as a contribution towards advertising expenses; and regarding the Fair as a means of expanding British industry, the Committee urges that the recommended national contribution is insignificant compared to the present expenditure on unproductive relief of unemployment which it is designed to reduce.

Other recommendations include the acquisition of a site easily accessible from central London, and its equipment with buildings capable of extension as required; the continuance and, if possible, supplementing of the Government banquet to celebrate the opening of the Fair; the establishing of a special Committee to direct the expenditure of the publicity grant, the administration of which and the management of the London Section should remain under the control of the Department of Overseas Trade; some extension of the hours of admission of the public to the London Section, stricter exclusion of the general public during the hours reserved for trade buyers, and an extension of the free passport *visa* granted to foreign buyers attending the Fair to cover at least three months and return visits to Great Britain during that time.

Lattice Distortion and the Hardening of Metals.

IT has hitherto been regarded almost as axiomatic that lattice distortion of a metal will result in hardening. Doubt of the universality of such a hypothesis is now justified, however, as the result of work done by W. L. Fink and K. R. van Horn, which formed the subject of a paper read on Sept. 10 before the Institute of Metals at its annual autumn meeting at Southampton.

The experiments recorded consisted in elastically deforming samples of 70:30 brass and duralumin by bending and, whilst still under stress, in measuring the hardness by the Rockwell apparatus on scale 'E'. X-ray examination was made simultaneously, and the effacement of the $K\alpha$ doublet, the diffuseness or elongation of the reflection images, and the widening of the diffraction rings, proved that lattice distortion had in fact been produced.

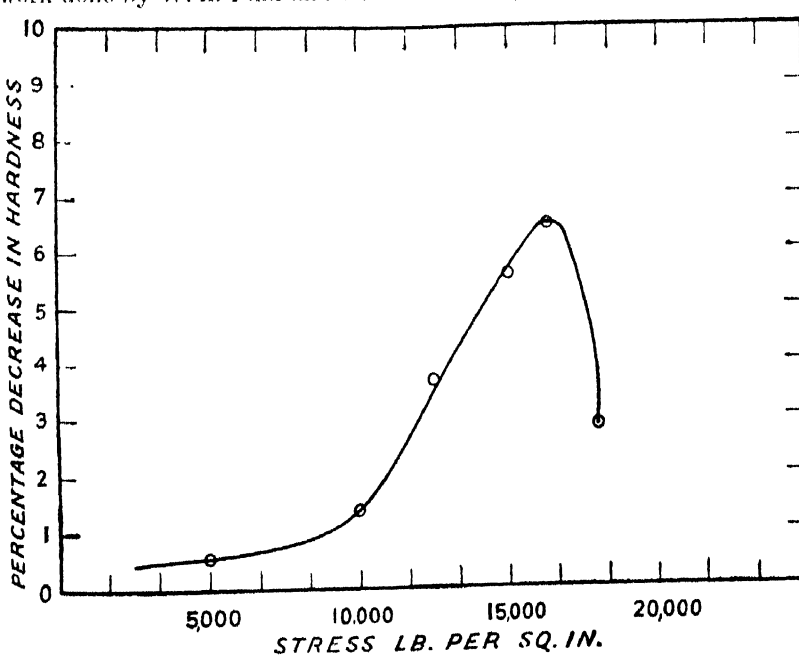

FIG. 1.—Relation between hardness and stress in duralumin. Reproduced by courtesy of the Institute of Metals.

In Fig. 1 the changes in hardness for the duralumin specimen are shown in relation to the stress set up. The material is at first softened and not hardened, the softening increasing with the stress up to the elastic limit. At stresses higher than this, the hardening resulting from the plastic deformation counteracts the softening effect and hardening commences. An exactly similar result was given by the work on the brass, which softened even more than did the aluminium alloy.

It is clear, then, that lattice distortion resulting from elastic deformation can be accompanied by an appreciable decrease in hardness. As the authors point out, however, it is conceivable that where lattice distortion is of a very local character, it may have the opposite effect and harden the material.

In corroboration of the results which have been obtained, the authors cite measurements made by Gayler and Preston on the aluminium alloy with 4·5 per cent of copper and by Chartkoff and Sykes on iron alloyed with 25 per cent of tungsten. In the former case, a specimen quenched from 500° C. and then aged first at room temperature and then for 3 hours at 200° C., which showed maximum lattice distortion, had a Brinell hardness number of 57.

The same specimen after an additional 21 hours at 200° C. had reached a maximum hardness of 78 but with considerably reduced distortion. The iron-tungsten alloy, which had been quenched from 1520° C., had a Rockwell 'C' hardness of 14 and pronounced lattice distortion. This alloy after a subsequent ageing for 40 hours at 800° C. was relatively free from strain but the hardness had risen to 39.

It would appear, then, that lattice distortion resulting from the precipitation of a new phase will, in some cases at least, reach a maximum and then partially disappear before the stage of greatest mechanical hardness has been attained. F. C. T.

University and Educational Intelligence.

THE eighteenth election to Beit Fellowships for Scientific Research, which are of the annual value of £250 and tenable at the Imperial College of Science and Technology, will take place on or about July 14 next. Not more than three fellowships will be awarded. Candidates must be less than twenty-five years of age at the time of election. Applications must be received by April 14. Particulars can be obtained, by letter only, from the Rector, Imperial College, South Kensington, London, S.W.

THE following scholarships will be offered for competition by the Institution of Naval Architects in 1931: *Naval Architecture*—Elgar Scholarship (£130 per ann. for 3 years) and the Vickers-Armstrong Scholarship (£150 per ann. for 3 years). *Marine Engineering*—Parsons Scholarship (£150 per ann. for 3 years) and the Denny Scholarship (£75 per ann. for 4 years). The Denny Scholarship is open to boys less than nineteen years of age who have not yet begun their apprenticeship, and is tenable at the University of Glasgow. The remaining scholarships are open to apprentices between the ages of eighteen and twenty-three, and are tenable at the Royal Naval College, Greenwich; University of Glasgow; Armstrong College; University of Liverpool; and the City and Guilds (Engineering) College. Particulars can be obtained from the Secretary of the Institution of Naval Architects, 2 Adam Street, Adelphi, London, W.C.2.

THE Meldola Medal (the gift of the Society of Maccabæans) is awarded annually to the chemist whose published chemical work shows the most promise and is brought to the notice of the administrators during the year ending Dec. 31 prior to the award. The recipient must be a British subject, not more than thirty years of age at the time of the completion of the work. The medal may not be awarded more than once to the same person. In awarding the medal for 1930 the adjudicators will, unless exceptional circumstances arise, give special consideration to work in inorganic or physical chemistry. The next award will be made in January, 1931. The medal is awarded on the advice of the board of examiners of the Institute of Chemistry sitting with representatives of the Society of Maccabæans. Communications should be addressed to the Registrar of the Institute of Chemistry, 30 Russell Square, London, W.C.1.

THE Commonwealth Fund of New York City, supported by gifts from the late Mrs. Stephen V. Harkness, has established for British graduate students a number of fellowships tenable at American universities. The fellowships are normally tenable for two years and are of the annual value of about £600. Thirty fellowships are available to graduates, either men or women, who are unmarried and not more than thirty years of age on Sept. 1; and ten are available to colonial graduates who have studied at a university in the British Isles and to graduates holding an appointment overseas under the British Government, the Government of India, or the Government of a British Dominion, Colony, Protectorate, or Mandated Territory. Candidates are required to produce evidence of proficiency in some recognised branch of university learning, and must also submit a definite scheme of research or study proposed to be carried out during their residence in the university to which they may be assigned. Applications must be forwarded through the authorities of the candidate's college or university and must reach the Secretary to the Committee, Mr. R. H. Simpson, 35 Portman Square, London, W.1, by Feb. 9, 1931, at latest. In 1930 the number of entries for ordinary and Dominion fellowships was 128 (104 men and 24 women); 35 candidates entered for the Service fellowships and three were appointed. Of the 32 fellows appointed, 20 came from the Faculty of Science and 12 belonged to the group of arts subjects.

Historic Natural Events.

Dec. 28, 1879. The Tay Bridge Storm.—On the evening and night of Dec. 28 a deep barometric depression passed along the north-west and north coasts of Scotland, moving north-eastwards. Violent gales from west and south-west were experienced over Scotland, the velocity reaching 88 miles per hour at Glasgow from 7.15 to 7.18 P.M. The storm is memorable for the destruction of the Tay Bridge at Dundee. The central raised portion of the bridge, 1050 yards long, broke away and at 7.30 P.M. a train and 75 persons, not one of whom was saved, plunged into the river. It seems probable that the bridge actually fell while the train was crossing. The wind at the time was blowing from west-south-west, almost directly across the bridge, and a continuous stream of sparks came from the wheels as the train passed across, caused probably by the force with which they were pressed against the lee rails. The bridge had only been opened to traffic on June 1, 1878; its rapid destruction showed that insufficient allowance had been made for the pressure of the wind, and led to a number of detailed studies on this subject.

Dec. 28, 1908. Messina Earthquake. The earthquake was very destructive within an area of less than 200 square miles. It is estimated that 75,000 persons (about half the total population) were killed in Messina, and 25,000 in Reggio and other places in Calabria. Less than ten minutes after the earthquake, both shores of the straits were swept by sea waves, which reached a height of 35 ft. on the Calabrian and 28 ft. on the Sicilian coast. A new series of levels made soon after the earthquake showed that both coasts had subsided, the Calabrian coast by 2[illegible] inches and the other by 28 inches.

Dec. 28-29, 1914. Gale off Dutch Coast.—One of the most violent gales of recent years struck the coast of Holland on the night of Dec. 28-29, 1914, after a very stormy month. On the morning of Dec. 29 the wind velocity at the Hook of Holland reached 94 miles per hour, and great damage was done to shipping. The gale was notable also for its long duration and great extent.

Dec. 30, 1788. Severe Cold in France.—It is recorded in the register of the Canton of La Châtre, Department of l'Indre, that "the frosts have been so severe this year in the month of December that the barometers (*sic*) have fallen two degrees lower than in 1709, especially Dec. 30. The snows covered the ground for more than six weeks."

Societies and Academies.

LONDON.

Linnean Society, Dec. 4.—**J. McLuckie**: On a natural *Grevillea* hybrid. Its hybrid character was first suggested by Fletcher and Musson (Linn. Soc. N.S.W., 1927) on facts of distribution and morphology. A comparative analysis of the hybrid and its putative parents is given. Two distinct types of *G. Gaudichaudii* occur in Nature, and their graphs reveal their differences. It has been synthesised artificially, and hybrid seedlings of the F_1 generation obtained. The experimental work reveals the comparative sterility of all three 'species'. The facts of distribution of *G. Gaudichaudii*, the results of a detailed analysis of its main morphological characters and of synthetic experiments in progress, seem to indicate that it is a natural hybrid between *G. laurifolia* and *G. acanthifolia*.—**B. Storrow**: Some fluctuations in zoological populations during the nineteenth century. The periods of major change are well marked, and the region affected is from the coast of Portugal to Spitsbergen. An amelioration of winter climate was due to a northerly extension of warm water which influenced the Arctic; the changed Labrador Current affected the fishes of the American coast from Newfoundland to Cape Cod. Local and widespread change, 1870–80, coincided with an increased contribution to the North Atlantic from the South Equatorial Current. The axis of the Gulf Stream approached nearer to the American coast, and the southward effect of the Labrador Current decreased. Such a change increases intermediate area of the North Atlantic. Variations in circulation and the incidence of fisheries become possible.

DUBLIN.

Royal Irish Academy, Nov. 10.—**E. J. Conway**: A statistical analysis of the law governing the urea excretion in man. The validity of an equation expressing the excretion of urea in the human subject has been demonstrated by statistical methods. This equation is similar in form to a diffusion equation and in fact only a special case of a general equation expressing either diffusion or secretion. The K of the equation is independent of the variables urine volume, blood concentration, and body weight. The influence of other unknown variables on K manifests itself in a peculiar frequency distribution.

EDINBURGH.

Royal Society, Dec. 1.—**G. Bond**: The stem endodermis in the genus *Piper*. In one group a continuous endodermis is present, in a second the layer present but is in a discontinuous condition, while a third group it is quite absent. This and other examples of variation in closely related types suggests that the stem endodermis can have little importance. The endodermis in *Piper* is also characterised by its persistence in the primary condition, its power of accommodation to the increasing bulk of the vascular cylinder, and by the irregular deposition of Casparian strips. In *Piper*, and possibly elsewhere, the Casperian strip is probably secreted by the endodermal protoplast.—**Alastair Graham**: On the morphology, feeding mechanisms, and digestion of *Ensis siliqua* Schumacher. There may be three or four apertures in the mantle—two posterior siphons and an anterior pedal aperture are of constant occurrence, but there may be a fourth aperture about the middle of the ventral surface. The foot contains six finite series of muscles and in the young animal a well-developed byssus gland of which no trace remains in the adult. The muscles and nervous system (remarkable for the large number of peripheral anastomoses) are described in detail. A comparison of the ciliary mechanisms of *Ensis* with those of other lamellibranchs, for example, *Ostrea*—an animal with widely different habits leads to the conclusion that throughout the class (except the septibranchs) these mechanisms will be found to be very similar. The style contains a strong amylase and also an oxidase; the digestive diverticula contain a protease, a lipase, a diastase, and a glycogenase.—**L. Mirskaia** and **F. A. E. Crew**: On the pregnancy rate in the lactating mouse, and the effect of suckling on the duration of pregnancy. Among primiparæ the pregnancy rate during lactation was found to be 24 per cent, among multiparæ 50 per cent, the difference being possibly a reflection of a difference in degree of somatic maturity. In all the cases of pregnancy during lactation the duration of gestation was prolonged. The figures do not confirm Daniel's law. Prolongation is due to an insufficiency of the hormone(s) responsible for the inception and maintenance of pregnancy.—**B. P. Wiesner**: Further observations on the mechanism of the diphasic sex cycle. Œstrogenic extracts from the anterior lobe and the gonadotropic substance of pregnancy urine interrupt pregnancy in mice in certain concentrations, but do not interfere with its progress in high concentration. The experiments are interpreted as supporting Wiesner and Crew's theory of the existence of two gonadotropic hormones. No gonadotropic hormones were found in placentæ of diphasic animals. The second phase of anterior lobe secretion in the mouse persists at least up to the twelfth day of pregnancy.

CAPE TOWN.

Royal Society of South Africa, Sept. 24. **E. Newbery**: The theory of electrolytic valve action. An insulating anodic film is built up, which is impermeable to the large anions usually present but permeable to hydrogen ions. As the films are very thin and the hydrogen ions very rapid, there is no difficulty in accounting for the observed rapid changes of potential and all the known phenomena of electrolytic valve action.—**B. F. J. Schonland**: Thunderstorms and the penetrating radiation (2). Thunderclouds which seem to have an excess positive charge elevated above a negative charge produce much larger reductions in the intensity of the penetrating radiation than the more usual type. This can be readily interpreted if the primary radiation consists either of positively charged particles or of ultra-gamma quanta, but it does not support the view that the radiation is made up of fast beta rays.—**C. van Riet Lowe**: Giant crescents. The term 'giant crescent' is used to describe an artefact that characterises a hitherto unnoted and unrecorded culture in the Stone Age of South Africa. Since the discovery of an isolated specimen by Stapleton at the Kasouga River mouth more than five years ago, a number of others have been found associated with a well-defined industry that was practised from Mazeppa to Algoa Bay along the south coast and so far inland as the Orange River an area that covers about 20,000 square miles. Technically and typologically the culture represents a transition from the Middle to the Later Stone Age and probably formed an integral part of a blending or contact between palæanthropic and neanthropic folk, the main influence being neanthropic. It shows remarkable affinities with the Late Mousterian and Early Aurignacian industries of Europe.—**A. C. Leeman**: Holism.

CRACOW.

Polish Academy of Science and Letters, July 7.—**St. Ziemecki**: An apparatus for the study of the Raman spectra of organic compounds. The apparatus proposed by Raman has been modified so as to permit the use of so little as 20 c.c. of liquid under examination. The experimental tube is placed in a bath of paraffin oil, which has the effect of reducing the reflections on the walls. The author considers that the study of the Raman spectrum of a substance will probably be regularly employed in organic laboratories.—**L. Marchlewski** and **Mlle. B. Charlampowiczówna**: The absorption of ultra-violet rays by certain organic substances.—**Mlle. A. Kozlowska**: The genetic elements of the steppe flora in Poland.—**L. Ejsmont**: *Astiotrema emydis*, a trematode of *Emys orbicularis*.—**E. Godlewski, jun.**: New researches on the phenomena of agglutination of the spermatozoids by sperm and by substances drawn from the organism of other species.—**S. Skowron** and **Mme. H. Skowron**: The action of tripaflavine on the karyokinetic division of the cell.—**T. Pawlas** and **S. Skowron**: The action of colouring matters derived from acridine on the male sexual cells and their production.—**Mme. Z. Kolodziejska** and **Mlle. W. Halber**: The chemical nature of the cancerous antigen. **Wl. Florkowski**: The lymphatic vessels of the head of the eel (*Anguilla anguilla*).—**A. Dunajewski**: The lymphatic vessels of the body of the eel (*Anguilla anguilla*). **P. Socha**: The development of the blood vessels in the brain of the frog.—**T. Marchlewski** and **Br. Slizynski**: The influence of prolonged selection on the development of a vestigial organ. An account of an attempt to increase the average length of the wings in the winged varieties of *Drosophila ampelophila*. **T. Marchlewski**: The craniology of the domestic dog.—**T. Marchlewski**: Certain factors determining the hereditary transmission of an abundant milk production in cows.—**J. Borowik**: The migration of *Pleuronectes limanda* in the central part of the Baltic.—**J. Borowik**: Marking *Pleuronectes* in the bay of Dantzig.

ROME.

Royal National Academy of the Lincei, May 30.—**U. Cisotti**: Isotropic tensors and hemi-isotropic tensors.—**G. Abetti**: Altitude of the chromosphere in 1929 and the course of the present solar cycle. Observations at Arcetri and Madrid in 1929 show that the total area of the solar protuberances (measured in units of protuberance), which fell by 53 from 1927 to 1928, diminished by 156 from 1928 to 1929. Thus the maximum of the present solar cycle has passed.—**A. Angeli**: Constitution and reactions of isomeric diazohydrates. An answer is given to Hantzsch's objections to the author's results and to the conclusion that stereoisomerism alone explains all differences in behaviour between normal diazohydrates and their isomerides.—**G. Bruni** and **G. Natta**: The crystal structure of thiophen. X-ray investigation of the crystal structure of thiophen by the powder method, with the aid of a special spectrograph adapted for use at low temperatures, shows that the crystal has a tetragonal cell with the axial ratio $a : c = 1 : 1 \cdot 32$. The lattice constants at -170° are: $a = 7 \cdot 225$, $c = 9 \cdot 54 \pm 0 \cdot 01$ A., $v = 498 \times 10^{-24}$ c.c. The unit cell contains four molecules C_4H_4S, and the density is 1·11. Use was made in the measurements of a metallic calcium anti-cathode, application of which is particularly advantageous in the examination of organic substances.—**S. Franchi**: Uniformity in character of the *Helmynthoida labyrinthica* zone from Ubaye to the Alps and to the Ligurian coast, and consequently its great chronological value.—**G. Levi** and **G. C. Dogliotti**: Structure and properties of the striated and reticula[r] fibrils in certain living tissues. The actual existenc[e] of these fibrils is demonstrated in a number of livin[g] organs, namely, the spleen, lymphatic glands, thymu[s] marrow, liver, kidneys. Study of the resistance t[o] tension of the fibrils in the spleen and liver by mean[s] of Péterfi's micro-manipulator shows that the fibril[s] are elastic in the ordinary sense of the term.—**G. Andreoli**: Limits and pseudo-limits of a succession. **Giuseppina della Moglie**: Study and tabulation of a particular function.—**Miron Nicolesco**: Theorems of the mean for functions of two real variables.—**Enrico Volterra**: Determination of the tensions in an elastic medium due to a small displacement of an immersed rigid sphere.—**F. Lamberti**: Investigations on the baricentric, scalar, and vectorial moments of the quantities of motion for a material system. **D. Bonvicini**: Certain fundamental theorems of electrodynamics and of the statics of elastic solids.—**E. Fermi**: Interpretation of the principle of causality in quantistic mechanics. An attempt is made to defin[e] up to what point causality may, according to quantisti[c] mechanics, be spoken of, and in what sense the statement that quantistic mechanics does not lead to a determination of future events, is to be understood. The case discussed is that of a point movable along a straight line, but the considerations advanced may b[e] readily extended to more complicated systems.—**E. Persico**: The relation $E = h\nu$ in wave mechanics. **Washington del Regno**: The laws of emission o[f] nickel. The few results yet published on the radiation of nickel indicate that the total emission of th[e] metal may be expressed by a relation of the Stefan Boltzmann type, $E = KT^n$, but somewhat divergen[t] values have been obtained for n by different investigators. By means of an experimental arrangemen[t] simpler and more certain in the determination of th[e] temperature of the emitting lamina than thos[e] previously used, the value 4·586 is obtained for [n] over the extended temperature interval 360°-60°. **G. Wataghin**: Seizure of electrons by ions. Applicatio[n] of the methods of wave mechanics is capable of furnishing an interpretation of the recent experimenta[l] results of Davis and Barnes on the seizure of electron[s] by α-particles.—**V. Ronchi**: Shadow fringes in th[e] study of very small spherical aberrations. Investigation of simple spherical aberration by means of shado[w] fringes shows that the deformations to which the fringes are subject are appreciable even when th[e] images no longer reveal the presence of spheric[al] aberration.—**G. R. Levi** and **D. Ghiron**: Oxidation [of] chlorites to chlorates by means of permanganate. This oxidation takes place quantitatively in col[d] neutral solution and is rendered more rapid by th[e] presence of salts of calcium, zinc, etc., which neutralis[e] the alkalinity of the process:

$$3ClO_2^- + 2MnO_4^- + 2H_2O \rightarrow 3ClO_3^- + 2MnO_2 + 2OH^-.$$

The course of the reaction is not disturbed by exce[ss] of the permanganate.—**G. Natta** and **A. Nasini**: Structure of inert gases (1). Investigation of xen[on]. At about 100° absolute, the side of the unit cell [of] xenon has the value $a = 6 \cdot 18 \pm 0 \cdot 02$ A., the volum[e] being 236×10^{-24} c.c., and the density, assuming th[at] the cell contains four atoms and taking $1 \cdot 65 \times 10$ gram as the weight of the hydrogen atom, 3·64. Th[is] value for the density corresponds with the expe[ri]mental value for liquid xenon at its boiling poin[t], namely, 3·06. On the assumption of the tangency [of] spherical atoms in the lattice, the apparent radius [of] the xenon atom is 2·18 A.—**A. Ostrogovich** and **Galea**: Investigations on γ-triazines. Syntheses [of] ethyl- and propyl-aminothioltriazines, and new dat[a] on methylaminothioltriazine. The conditions f[or] obtaining the higher homologues of methylaminothi[o]

triazine and aryl and arylalkyl derivatives of aminothioltriazine are given. The ethyl compound melts at 257°-258° and the propyl compound at 262°-263°. —**A. Desio**: The presence of the fossiliferous Silurian in the island of Coo (Ægean Sea).—**Romolo de Fazi**: Action of ultra-violet rays on the germination of barley for malting. The effects of the action of ultra-violet rays on germinating barley include acceleration of the germinating process, prevention of mould growth, and increase in the vitamin content. This treatment is found to be applicable, with beneficial results, to the manufacture of malt under industrial conditions.—**C. Guareschi**: First experimental results on the development of the otocysts of urodele amphibia. By means of a new experimental procedure, it is shown for the first time that the otocysts of urodele amphibia form a mosaic system.

SYDNEY.

Linnean Society of New South Wales, Sept. 24. **J. R. Malloch**: Notes on Australian Diptera (26). The group treated in previous papers in this series as subfamily Ochthiphilinæ is now regarded as of family rank. Keys are given to the genera.—**A. M. Lea**: Descriptions of new species of Australian Coleoptera (21). Eleven new species of Scarabæidæ and thirteen new species and five new genera of Curculionidæ, mostly from Australia, and three species from Fiji and two from Papua closely allied to Australian forms, are also described.—**J. Calvert**: An abnormal *Xanthium* burr. A burr in which two male florets occupy portion of the burr, whilst just alongside, a loculus contained what looked like an unopened floret. This made up one half of the burr, the other half consisting of the normal one-seeded loculus.—**W. W. Froggatt**: Notes on gall-making coccids, with descriptions of new species (2). Five species of *Apiomorpha* are described as new. In some cases the specific names of the Eucalypts on which the galls develop, which were previously unknown, are recorded. **C. Deane**: Trichopterygidæ of Australia and Tasmania: descriptions of new genera and species. Hitherto only six species of Trichopterygidæ had been described from Australia. The present paper adds eleven new species, classed in eight genera, six of which are new, most of them being very distinct. One new genus is blind, there being no eyes or eye sockets, nor any suggestion of a place for the eyes. *Rodwayia* is also blind, but differs in most other ways.

Diary of Societies.

TUESDAY, DECEMBER 30.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. M. Tyndall: The Electric Spark (1): Some Properties of Electrified Bodies (Juvenile Lectures).

WEDNESDAY, DECEMBER 31.

BRITISH ASTRONOMICAL ASSOCIATION (at Sion College, Victoria Embankment), at 5.

THURSDAY, JANUARY 1.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. M. Tyndall: The Electric Spark (2): The Spark as a Current of Electricity (Juvenile Lectures).

FRIDAY, JANUARY 2.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—S. J. Davies: An Experimental Investigation into Induction Conditions, Distribution, and Turbulence in Petrol-Engines.

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section) at 7.—E. Fawssett and G. E. Moore: Apparatus and Methods for Accurate Maintenance of Large A.C. Energy Meters.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group Informal Meeting), at 7.—Discussion on Portfolio Prints.

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7.30.—W. A. Benton: Weighing Machinery.

GEOLOGISTS' ASSOCIATION (in Architectural Theatre, University College), at 7.30.—Dr. F. Smithson: The Triassic Sandstones of Yorkshire and Durham.—E. St. John Burton: Periodic Changes in Position of the Run, near Mudeford, Christchurch, Hants.

SATURDAY, JANUARY 3.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. M. Tyndall: The Electric Spark (3): Air as a Conductor of Electricity (Juvenile Lectures).

CONFERENCES.

DECEMBER 31 TO JANUARY

GE

Wednesday, Dec. 31 (at Imperial Institute), at 5.30.—Suez Canal Film to be shown by Sir J. T. Davies.

Thursday, Jan. 1 (at London School of Economics).

At 11.30 A.M.—School Journeys Exhibition and Discussion.

At 2.—B. B. Dickinson: Presidential Address.

At 3.45.—Exhibition of Maps showing Agricultural Distributions in Scotland, prepared by H. J. Wood.

At 5.30.—A Regional Study of the Chod Villages of S.W. Bohemia—a Field Study by a Leplay House Group, with an Exhibit of Original Maps and Files of this and other Regions.

Friday, Jan. 2 (at London School of Economics).

At 10 A.M.—Major R. W. G. Hingston: In the Tree-Roof of the Guiana Forest (Lecture).

At 11.30 A.M.—Miss R. M. Fleming: Regions of Russia (Lecture).

At 2.30.—Meeting for Teachers in Secondary Schools for Discussion on a paper by B. C. Wallis on School Geography from the Point of View of an Examiner.

Meeting for Teachers in Primary Schools:—Geography and the Extension of the School Age. Discussion to be opened by E. J. Orford.

Saturday, Jan. 3 (at London School of Economics).

At 10.15 A.M.—Dr. P. W. Bryan: The Distribution of Houses in England and Wales as a Population Index (Lecture).

DECEMBER 31 TO JANUARY 7.

CONFERENCE OF EDUCATIONAL ASSOCIATIONS (at University College).

Wednesday, Dec. 31, at 3.—Sir Richard Gregory: The Worth of Science (Presidential Address).

FROEBEL SOCIETY AND JUNIOR SCHOOLS ASSOCIATION.

At 5.30.—J. Howard Whitehouse: Ideals and Methods in Education (Presidential Address).

BRITISH PSYCHOLOGICAL SOCIETY (EDUCATION SECTION).

At 5.30.—Prof. T. H. Pear: Learning how to Study (Lecture).

NEW EDUCATION FELLOWSHIP.

Thursday, Jan. 1, at 5.—Discussion on The Efficiency of the First School Examinations and their Relation to Matriculation.

SCHOOL NATURE STUDY UNION.

At 3.—Sir J. Arthur Thomson: The Beauty and Wonder of the World (Lecture).

UNIVERSITY OF LONDON ANIMAL WELFARE SOCIETY.

At 5.—Mrs. Susan Isaacs, Miss S. M. Wortman, O. H. Latter, and Capt. C. W. Hume: Discussion on Humane Education in Schools.

DALTON ASSOCIATION.

Friday, Jan. 2, at 11.—G. W. Spriggs: Individual Work in Mathematics (Lecture).

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

At 2.—Dr. A. G. Maitland-Jones and others: Discussion on Hours of Sleep and the School Child in Day and Public Schools.

CHILD-STUDY SOCIETY.

At 5.30.—Prof. J. E. Marcault: What is Religious in the Child (Lecture).

MODERN LANGUAGE ASSOCIATION.

Monday, Jan. 5, at 11 A.M.—Prof. E. W. Scripture and Prof. P. Menzerath: Discussion on Experimental Phonetics.

NATIONAL COLLEGE OF TEACHERS OF THE DEAF.

At 11 A.M.—Dr. J. Drever: The Educational Handicap of the Deaf from a Psychologist's Point of View (Lecture).

JOINT CONFERENCE.

At 5.—J. Fairgrieve, Lt.-Gen. Sir William Furse, Miss B. Hosgood, C. B. Thurston: The Teaching of Geography. Chairman: Sir Richard Gregory.

CENTRAL COUNCIL FOR SCHOOL BROADCASTING.

Tuesday, Jan. 6, at 11 A.M.—Prof. Winifred Cullis and others: The Teaching of Biology by Wireless (Lecture-Demonstration).

BRITISH SOCIAL HYGIENE COUNCIL.

At 5.—Dr. H. Crichton Miller: Marriage, Freedom, and Education (Lecture).

MATHEMATICAL ASSOCIATION (at London Day Training College).

Monday, Jan. 5, at 3.30.—Sir Arthur S. Eddington: The End of the World (from the standpoint of Mathematical Physics) (Presidential Address).

At 5.—Prof. A. R. Forsyth: Dimensions in Geometry.

Tuesday, Jan. 6, at 10 A.M.—A. Robson and others: Discussion on The Report on the Teaching of Mechanics in Schools.

At 11.30 A.M.—W. Hope Jones, Dr. F. J. W. Whipple, P. M. Marples and others: Discussion on Gambling.

At 2.30.—Prof. J. E. A. Steggall: Faith and Reason in beginning the Calculus and Elsewhere.

At 3.45.—Prof. E. H. Neville: Limits in Geometry.

JANUARY 6 TO 9.

SCIENCE MASTERS' ASSOCIATION (at University, Birmingham).

Tuesday, Jan. 6, at 8.30 P.M.—Sir Charles Grant Robertson: Presidential Address.

Wednesday, Jan. 7, at 10.15 A.M.—J. Young: The Lunar Landscape (Lecture).

At 11.30 A.M.—Prof. W. N. Haworth: An Insight into Complex Molecular Structures (Lecture).

At 6.—Prof. Nash: The Work of the Physicist and Chemist in the Petroleum Industry (Lecture).

At 8.15.—The Lord Bishop of Birmingham: A Finite Universe (Lecture).

Thursday, Jan. 8, 10 to 11.15 A.M.—F. Fairbrother and others: Discussion on General Science.

At 12.—Prof. K. N. Moss: Scholarships offered in Coal Mining and Metal Mining.

6 to 7.15.—Prof. F. W. Burstall: The Science Education of the Boy up to Eighteen Years of Age (Lecture).

At 8.30.—Meeting of S.M.A. with Representatives of the Commission on Educational and Cultural Films.

Friday, Jan. 9, at 10 A.M.—Prof. H. Munro Fox: Zoological Experiments for School Work.

EXHIBITION.

JANUARY 6 TO 8.

PHYSICAL AND OPTICAL SOCIETIES' EXHIBITION OF ELECTRICAL, OPTICAL AND OTHER PHYSICAL APPARATUS (at Imperial College of Science and Technology), at 3 to 6, and 7 to 10.

Wednesday, Jan. 7, at 8 P.M.—E. Lancaster-Jones: Searching Minerals with Scientific Instruments (Lecture).

Thursday, Jan. 8, at 8 P.M.—Sir Gilbert Walker: Physics of Sport (Lecture).

Recent Scientific and Technical Books.

Volumes marked with an asterisk have been received at "NATURE" Office.

Mathematics: Mechanics: Physics

Batten, T. C., and Brown, M. W. A School Algebra. Cr. 8vo. Part 1. Pp. x+198. (London: John Murray, 1930.) 3*s*.; with Answers, 3*s*. 6*d*.

Bieberbach, Ludwig. Theorie der Differentialgleichungen. (Die Grundlehren der mathematischen Wissenschaften in Einzeldarstellungen mit besonderer Berücksichtigung der Anwendungsgebiete, herausgegeben von R. Courant, Band 6.) Dritte neubearbeitete Auflage. Roy. 8vo. Pp. xii+399. (Berlin: Julius Springer, 1930.) 21 gold marks.

Brillouin, Léon. La théorie des quanta. Deuxième édition. Les statistiques quantiques et leurs applications. (Recueil des Conférences-Rapports de documentation sur la Physique, Vol. 18.) Roy. 8vo. Vol. 1. Pp. 192. Vol. 2. Pp. 193-404. (Paris: Les Presses universitaires de France, 1930.) 125 francs.*

Broglie, Louis de. An Introduction to the Study of Wave Mechanics. Translated from the French by H. T. Flint. Demy 8vo. Pp. xi+249. (London: Methuen and Co., Ltd., 1930.) 12*s*. 6*d*. net.*

Broglie, Maurice de, und Broglie, Louis de. Einführung in die Physik der Röntgen- und Gamma-Strahlen. Übersetzt von L. von Seuffert. Roy. 8vo. Pp. viii+208+11 Tafeln. (Leipzig: Johann Ambrosius Barth, 1930.) 21 gold marks.

Brünold, Charles. L'Entropie: son rôle dans le développement historique de la thermodynamique. Roy. 8vo. Pp. v+221. (Paris: Masson et Cie, 1930.) 30 francs.*

David, Pierre. L'Électro-acoustique: rapports de l'acoustique moderne et de l'électricité. Conférence faite au Conservatoire National des Arts et Métiers le 9 mai 1930. (Conférences d'actualités scientifiques et industrielles, 11.) Roy. 8vo. Pp. 39. (Paris: Hermann et Cie, 1930.) 5 francs.*

Deans, W. M. Examples in Elementary Algebra. Gl. 8vo. Pp. 47. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1930.) 1*s*.

Dedekind, Richard. Gesammelte mathematische Werke. Herausgegeben von Robert Fricke, Emmy Noether und Öystein Ore. Band 1. Roy. 8vo. Pp. iii+397. (Braunschweig: Friedr. Vieweg und Sohn A.-G., 1930.) 30 gold marks.

Deltheil, R. Erreurs et moindres carrés. (Traité du calcul des probabilités et de ses applications, par Émile Borel. Tome 1: Les principes de la théorie des probabilités, Fascicule 2.) Roy. 8vo. Pp. vi+161. (Paris: Gauthier-Villars et Cie, 1930.) 30 francs.*

Department of Scientific and Industrial Research: Illumination Research. Technical Paper No. 9: Reflection from Road Surfaces. By A. K. Taylor. Roy. 8vo. Pp. v+19. (London: H.M. Stationery Office, 1930.) 6*d*. net.*

Dobson, Charles G. The Arithmetic of Building. (Lockwood's Manuals.) Second edition, revised. Cr. 8vo. Pp. vii+84. (London: Crosby Lockwood and Son, 1930.) 2*s*. 6*d*. net.

Dougall, John, Arranged by. Test Papers in Algebra and Geometry. Gl. 8vo. Pp. 40. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1930.) 1*s*.

Dresden, Arnold. Solid Analytical Geometry and Determinants. 8vo. Pp. 310. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1930.) 15*s*. net.

Gosselin, Albert, et Gosselin, Marcel. Constitution et thermochimie des molécules: les constituants moléculaires, les liaisons intramoléculaires, la valeur énergétique des liaisons. Sup. Roy. 8vo. Pp. vii+231. (Paris: Les Presses universitaires de France, 1930.)*

Guiller, George L. Kinematics of Machines. Second edition. 8vo. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1930.) 15*s*. net.

Hadamard, J. Cours d'analyse professé à l'École polytechnique. Tome 2: Potentiel, calcul des variations, fonctions analytiques, équations différentielles et aux dérivées partielles, calcul des probabilités. Roy. 8vo. Pp. vi+721. (Paris: Hermann et Cie, 1930.) 140 francs.*

Heisenberg, W. Die physikalischen Prinzipien der Quantentheorie. Med. 8vo. Pp. viii+117+2 Tafeln. (Leipzig: S. Hirzel, 1930.) 7 gold marks.*

Hilbert, D. Grundlagen der Geometrie. (Wissenschaft und Hypothese, Band 7.) Siebente umgearbeitete und vermehrte Auflage. 8vo. Pp. vii+326. (Berlin und Leipzig: B. G. Teubner, 1930.) 18 gold marks.

Holmyard, E. J. Physics for Beginners. (Dent's Modern Science Series.) Gl. 8vo. Pp. viii+160+8 plates. (London and Toronto: J. M. Dent and Sons, Ltd., 1930.) 2*s*. 6*d*.*

Humphrey, D. Intermediate Mechanics: Dynamics. (Longmans' Modern Mathematical Series.) Demy 8vo. Pp. x+382. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1930.) 10*s*. 6*d*.*

James, R. W. X-ray Crystallography. (Methuen's Monographs on Physical Subjects.) Fcap. 8vo. Pp. vii+88. (London: Methuen and Co., Ltd., 1930.) 2*s*. 6*d*. net.*

Julia, Gaston. Principes géométriques d'analyse. Première partie: Leçons faites à la Sorbonne. Re... et rédigées par Marcel Brelot. (Cahiers scientifiques, Fascicule 6.) Roy. 8vo. Pp. vi+116. (Paris: Gauthier-Villars et Cie, 1930.) 25 francs.*

Kirchner, Fritz. Experimental Physik der Röntgenstrahlen. Roy. 8vo. Pp. 584. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1930.) 55 gold marks.

Knowlton, A. A., and O'Day, Marcus. Laboratory Manual in Physics. Med. 8vo. Pp. xi+127. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1930.) 8*s*. 9*d*. net.*

Lewis, C. N. School Certificate Heat. (Pitman's School Certificate Series.) Cr. 8vo. Pp. vii+270. (London: Sir Isaac Pitman and Sons, Ltd., 1930.) 4*s*. 6*d*.

Mackenzie, A. H., and Forster, A. Theoretical and Practical Mechanics and Physics, with a Chapter on Chemistry: a Preliminary Science Course. Cr. 8vo. Pp. xviii+288. (London: Macmillan and Co., Ltd., 1930.) 3*s*.*

Mahler, Gottfried. Physikalische Aufgabensammlung. (Sammlung Göschen, Band 243.) Neu bearbeitet von Karl Mahler. Vierte verbesserte Auflage. Pott 8vo. Pp. 136. (Berlin und Leipzig: Walter de Gruyter und Co., 1930.) 1.80 gold marks.

Miles, Egbert J., and Mikesh, James S. Calculus. Med. 8vo. Pp. xiii+638. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1930.) 18*s*. 9*d*. net.*

Paget, Sir Richard. Babel: or the Past, Present and Future of Human Speech. (To-day and To-morrow Series.) Pott 8vo. Pp. 93. (London: Kegan Paul and Co., Ltd., 1930.) 2*s*. 6*d*. net.*

Painlevé, Paul, Professées par. Leçons sur la résistance des fluides non visqueux. Rédigées par A. Metral et R. Mazet. (Chaire de mécanique des fluides et applications.) Première partie. Rédigée par A. Metral. Roy. 8vo. Pp. viii+183. (Paris: Gauthier-Villars et Cie, 1930.) 40 francs.*

Painlevé, Paul, et Platrier, Charles. Cours de mécanique: mécanique des solides indéformables, mécanique des milieux continus déformables, théorie sommaire des machines et de l'aviation, les mécaniques de Newton et d'Einstein. (Cours de l'École polytechnique.) Demy 4to. Pp. viii+644. (Paris: Gauthier-Villars et Cie, 1929.) 150 francs.*

Palmer, C. I. Practical Mathematics. Part 1: Arithmetic, with Applications. Third edition. Cr. 8vo. Pp. 164. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1930.) 6*s*. 3*d*. net.
